    val idVersion7SpecificTime = Uuid.generateV7NonMonotonicAt(timestamp)
    println(idVersion7SpecificTime)
}
```

Parse UUIDs

UUID values are often represented as strings, such as in URL parameters or database records.

To convert a `String` value to a `Uuid` value, use the `Uuid.parse()` function:

```
import kotlin.uuid.Uuid

fun main() {
    val id = Uuid.parse("de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a")
    println(id)
}
```

The `Uuid.parse()` function accepts both the standard hex-and-dash format and the hexadecimal format without dashes.

If the input is invalid, the `Uuid.parse()` function throws an `IllegalArgumentException`:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val id = Uuid.parse("10")
    println(id)
}
```

If your application accepts only one representation, use the format-specific functions:

- `Uuid.parseHexDash()` for the hex-and-dash string representation.
- `Uuid.parseHex()` for the hexadecimal string representation without dashes.

For example:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val standard = Uuid.parseHexDash("de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a")
    val compact = Uuid.parseHex("de2bc56cea734f3c8a375a46fdb2d79a")

    println(standard)
    println(compact)
}
```

If you have UUIDs from external sources and must handle invalid input safely, use `Uuid.parseOrNull()`, `Uuid.parseHexDashOrNull()`, or `Uuid.parseHexOrNull()`. These functions return `null` if the input is invalid:

```
fun parseId(input: String): Uuid? {
    return Uuid.parseOrNull(input)
}
```

Convert UUIDs to strings

You can convert a `Uuid` value to a `String` value with the following functions:

- `toString()` for the standard string representation
- `toHexDashString()` for the hex-and-dash format
- `toHexString()` for the hexadecimal format without dashes

For example:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val id = Uuid.parse("de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a")

    println(id.toString())
    // de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a
    println(id.toHexDashString())
    // de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a
    println(id.toHexString())
    // de2bc56cea734f3c8a375a46fdb2d79a
}
```

Compare UUIDs

You can check whether `Uuid` values are equal using the `==` operator.

Kotlin compares values according to the UUID value, not to the textual representation. For example, two values in different forms are equal if they represent the same 128-bit value:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val first = Uuid.parse("de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a")
    val second = Uuid.parse("de2bc56cea734f3c8a375a46fdb2d79a")

    println(first == second)
    // true
}
```

This makes the `Uuid` comparison more reliable than comparing strings, which treats the same value in different formats as different values. `Uuid` comparison checks the actual identifier value.

`Uuid` implements the `Comparable<Uuid>` interface, so UUID values can be sorted with standard collection functions such as `sorted()`. In that case, Kotlin compares values lexicographically (from the most to the least significant bit):

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val first = Uuid.generateV7()
    val second = Uuid.generateV7()

    val sorted = listOf(first, second).sorted()
    println(sorted)
}
```

Work with binary representations

Some APIs, storage formats, and binary protocols do not represent UUIDs as strings. Instead, they store the 128-bit UUID value as either:

- A 16-byte array

- Two 64-bit values

Use these representations when you need to exchange UUIDs with systems that expect binary UUID data.

To convert between a UUID and a 16-byte representation, use the `.toByteArray()` and `Uuid.fromByteArray()` functions:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val id = Uuid.random()

    val bytes = id.toByteArray()
    val original = Uuid.fromByteArray(bytes)

    println(id)

    println(bytes)
    println(original)

    println(id == original)
    // true
}
```

You can also represent the same 128-bit UUID value as two `Long` values. This is useful because Kotlin doesn't provide a built-in 128-bit integer type. The two `Long` values store the UUID in two parts:

- The `mostSignificantBits` parameter for the first 64 bits of a UUID.
- The `leastSignificantBits` parameter for the last 64 bits of a UUID.

To create a `Uuid` value from two `Long` values, use the `Uuid.fromLongs()` function:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val id = Uuid.fromLongs(
        mostSignificantBits = -4653685776373167443,
        leastSignificantBits = -6288180676521310383.toLong()
    )
    println(id)
    // bf6ac971-52fd-4aad-a8bb-e4fdac78c751
}
```

To extract the two parts from an existing `Uuid` value, use the `Uuid.toLongs()` function:

```
import kotlin.uuid.Uuid

fun main() {
//sampleStart
    val id = Uuid.random()

    id.toLongs { mostSignificantBits, leastSignificantBits ->
        println(mostSignificantBits)
        println(leastSignificantBits)
    }
}
```

Serialize UUIDs

Kotlin supports serialization for `Uuid` values. Use it to store or transfer a UUID value outside Kotlin code, for example, in JSON APIs or configuration files.

To serialize a `Uuid` value, represent it as a string unless your application requires another format. The `kotlinx.serialization` library uses the hex-and-dash format:

```
//sampleStart
import kotlin.uuid.Uuid
import kotlinx.serialization.Serializable
import kotlinx.serialization.encodeToString
import kotlinx.serialization.json.Json

@Serializable
data class User(
    val id: Uuid,
    val name: String
)

fun main() {
    val user = User(
        id = Uuid.parse("de2bc56cea734f3c8a375a46fdb2d79a"),
        name = "Kotlin"
    )

    println(Json.encodeToString(user))
    // {"id":"de2bc56c-ea73-4f3c-8a37-5a46fdb2d79a","name":"Kotlin"}
}
```

Use UUIDs with Java APIs

Java uses the `java.util.UUID` class to represent UUIDs. On the JVM, Java APIs may accept or return this type. Although `java.util.UUID` and `kotlin.uuid.Uuid` both represent UUIDs, they are two distinct types.

Convert values explicitly to pass UUIDs between Kotlin and Java:

- Convert a Java UUID to Kotlin with the `.toKotlinUuid()` extension function:

  ```
  import kotlin.uuid.toKotlinUuid

  val kotlinId: Uuid = javaId.toKotlinUuid()
  ```

- Convert a Kotlin UUID to Java with the `.toJavaUuid()` extension function:

  ```
  import kotlin.uuid.toJavaUuid

  val javaId: java.util.UUID = kotlinId.toJavaUuid()
  ```

These functions allow you to represent your UUID values using `Uuid` at JVM interoperability boundaries.

The `java.util.UUID` and `kotlin.uuid.Uuid` classes are comparable, but the ordering may differ. Make sure to check your code that depends on UUID ordering before migrating from the Java API to the Kotlin API.

Kotlin also provides support for working with Java buffers. Use JVM-specific functions to work with UUIDs in a `ByteBuffer`:

- Use the `.getUuid()` function to read a UUID from a buffer.
- Use the `.putUuid()` function to write a UUID to a buffer.

Coroutines guide

Kotlin provides only minimal low-level APIs in its standard library to enable other libraries to utilize coroutines. Unlike many other languages with similar capabilities, `async` and `await` are not keywords in Kotlin and are not even part of its standard library. Moreover, Kotlin's concept of *suspending function* provides a safer and less error-prone abstraction for asynchronous operations than futures and promises.

`kotlinx.coroutines` is a rich library for coroutines developed by JetBrains. It contains a number of high-level coroutine-enabled primitives that this guide covers, including `launch`, `async`, and others.

This is a guide about the core features of `kotlinx.coroutines` with a series of examples, divided up into different topics.

In order to use coroutines as well as follow the examples in this guide, you need to add a dependency on the `kotlinx-coroutines-core` module as explained in the project README.

Coroutines basics

To create applications that perform multiple tasks at once, a concept known as concurrency, Kotlin uses *coroutines*. A coroutine is a suspendable computation that lets you write concurrent code in a clear, sequential style. Coroutines can run concurrently with other coroutines and potentially in parallel.

On the JVM and in Kotlin/Native, all concurrent code, such as coroutines, runs on *threads*, managed by the operating system. Coroutines can suspend their execution instead of blocking a thread. This allows one coroutine to suspend while waiting for some data to arrive and another coroutine to run on the same thread, ensuring effective resource utilization.

Comparing parallel and concurrent threads

For more information about the differences between coroutines and threads, see Comparing coroutines and JVM threads.

Suspending functions

The most basic building block of coroutines is the *suspending function*. It allows a running operation to pause and resume later without affecting the structure of your code.

To declare a suspending function, use the `suspend` keyword:

```
suspend fun greet() {
    println("Hello world from a suspending function")
}
```

You can only call a suspending function from another suspending function. To call suspending functions at the entry point of a Kotlin application, mark the `main()` function with the `suspend` keyword:

```
suspend fun main() {
    showUserInfo()
}

suspend fun showUserInfo() {
    println("Loading user...")
    greet()
    println("User: John Smith")
}

suspend fun greet() {
    println("Hello world from a suspending function")
}
```

This example doesn't use concurrency yet, but by marking the functions with the `suspend` keyword, you allow them to call other suspending functions and run concurrent code inside.

While the `suspend` keyword is part of the core Kotlin language, most coroutine features are available through the `kotlinx.coroutines` library.

Add the kotlinx.coroutines library to your project

To include the `kotlinx.coroutines` library in your project, add the corresponding dependency configuration based on your build tool:

Kotlin

```
// build.gradle.kts
repositories {
    mavenCentral()
}

dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
}
```

Groovy

```
// build.gradle
repositories {
    mavenCentral()
}

dependencies {
    implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
}
```

Maven

```
<!-- pom.xml -->
<project>
    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlinx</groupId>
            <artifactId>kotlinx-coroutines-core</artifactId>
            <version>1.11.0</version>
        </dependency>
    </dependencies>
    ...
</project>
```

Create your first coroutines

The examples on this page use the explicit `this` expression with the coroutine builder functions `CoroutineScope.launch()` and `CoroutineScope.async()`. These coroutine builders are extension functions on `CoroutineScope`, and the `this` expression refers to the current `CoroutineScope` as the receiver.

For a practical example, see Extract coroutine builders from the coroutine scope.

To create a coroutine in Kotlin, you need the following:

- A suspending function.
- A coroutine scope in which it can run, for example inside the `withContext()` function.
- A coroutine builder like `CoroutineScope.launch()` to start it.
- A dispatcher to control which threads it uses.

Let's look at an example that uses multiple coroutines in a multithreaded environment:

1. Import the `kotlinx.coroutines` library:

```
import kotlinx.coroutines.*
```

2. Mark functions that can pause and resume with the `suspend` keyword:

```
suspend fun greet() {
    println("The greet() on the thread: ${Thread.currentThread().name}")
}

suspend fun main() {}
```

While you can mark the `main()` function as `suspend` in some projects, it may not be possible when integrating with existing code or using a framework. In that case, check the framework's documentation to see if it supports calling suspending functions. If not, use `runBlocking()` to call them by blocking the current thread.

3. Add the `delay()` function to simulate a suspending task, such as fetching data or writing to a database:

```
suspend fun greet() {
    println("The greet() on the thread: ${Thread.currentThread().name}")
    delay(1000L)
}
```

4. Use `withContext(Dispatchers.Default)` to define an entry point for multithreaded concurrent code that runs on a shared thread pool:

```
suspend fun main() {
    withContext(Dispatchers.Default) {
        // Add the coroutine builders here
    }
}
```

> The suspending `withContext()` function is typically used for context switching, but in this example, it also defines a non-blocking entry point for concurrent code. It uses the `Dispatchers.Default` dispatcher to run code on a shared thread pool for multithreaded execution. By default, this pool uses up to as many threads as there are CPU cores available at runtime, with a minimum of two threads.
>
> The coroutines launched inside the `withContext()` block share the same coroutine scope, which ensures structured concurrency.

5. Use a coroutine builder function like `CoroutineScope.launch()` to start the coroutine:

```
suspend fun main() {
    withContext(Dispatchers.Default) { // this: CoroutineScope
        // Starts a coroutine inside the scope with CoroutineScope.launch()
        this.launch { greet() }
        println("The withContext() on the thread: ${Thread.currentThread().name}")
    }
}
```

6. Combine these pieces to run multiple coroutines at the same time on a shared pool of threads:

```
// Imports the coroutines library
import kotlinx.coroutines.*

// Imports the kotlin.time.Duration to express duration in seconds
import kotlin.time.Duration.Companion.seconds

// Defines a suspending function
suspend fun greet() {
    println("The greet() on the thread: ${Thread.currentThread().name}")
    // Suspends for 1 second and releases the thread
    delay(1.seconds)
    // The delay() function simulates a suspending API call here
    // You can add suspending API calls here like a network request
}

suspend fun main() {
    // Runs the code inside this block on a shared thread pool
    withContext(Dispatchers.Default) { // this: CoroutineScope
        this.launch() {
            greet()
        }

        // Starts another coroutine
        this.launch() {
            println("The CoroutineScope.launch() on the thread: ${Thread.currentThread().name}")
            delay(1.seconds)
            // The delay function simulates a suspending API call here
            // You can add suspending API calls here like a network request
        }

        println("The withContext() on the thread: ${Thread.currentThread().name}")
    }
}
```

Try running the example multiple times. You may notice that the output order and thread names may change each time you run the program, because the OS decides when threads run.

> You can display coroutine names next to thread names in the output of your code for additional information. To do so, pass the `-Dkotlinx.coroutines.debug` VM option in your build tool or IDE run configuration.
>
> See Debug coroutines for more information.

Coroutine scope and structured concurrency

When you run many coroutines in an application, you need a way to manage them as groups. Kotlin coroutines rely on a principle called *structured concurrency* to provide this structure.

According to this principle, coroutines form a tree hierarchy of parent and child tasks with linked lifecycles. A coroutine's lifecycle is the sequence of states from its creation until completion, failure, or cancellation.

A parent coroutine waits for its children to complete before it finishes. If the parent coroutine fails or gets canceled, all its child coroutines are recursively canceled too. Keeping coroutines connected this way makes cancellation and error handling predictable and safe.

To maintain structured concurrency, new coroutines can only be launched in a `CoroutineScope` that defines and manages their lifecycle. The `CoroutineScope` includes the *coroutine context*, which defines the dispatcher and

other execution properties. When you start a coroutine inside another coroutine, it automatically becomes a child of its parent scope.

Calling a coroutine builder function, such as `CoroutineScope.launch()` on a `CoroutineScope`, starts a child coroutine of the coroutine associated with that scope. Inside the builder's block, the receiver is a nested `CoroutineScope`, so any coroutines you launch there become its children.

Create a coroutine scope with the `coroutineScope()` function

To create a new coroutine scope with the current coroutine context, use the `coroutineScope()` function. This function creates a root coroutine of the coroutine subtree. It's the direct parent of coroutines launched inside the block and the indirect parent of any coroutines they launch. `coroutineScope()` executes the suspending block and waits until the block and any coroutines launched in it complete.

Here's an example:

```
// Imports the kotlin.time.Duration to express duration in seconds
import kotlin.time.Duration.Companion.seconds

import kotlinx.coroutines.*

// If the coroutine context doesn't specify a dispatcher,
// CoroutineScope.launch() uses Dispatchers.Default
suspend fun main() {
    // Root of the coroutine subtree
    coroutineScope { // this: CoroutineScope
        this.launch {
            this.launch {
                delay(2.seconds)
                println("Child of the enclosing coroutine completed")
            }
            println("Child coroutine 1 completed")
        }
        this.launch {
            delay(1.seconds)
            println("Child coroutine 2 completed")
        }
    }
    // Runs only after all children in the coroutineScope have completed
    println("Coroutine scope completed")
}
```

Since no dispatcher is specified in this example, the `CoroutineScope.launch()` builder functions in the `coroutineScope()` block inherit the current context. If that context doesn't have a specified dispatcher, `CoroutineScope.launch()` uses `Dispatchers.Default`, which runs on a shared pool of threads.

Extract coroutine builders from the coroutine scope

In some cases, you may want to extract coroutine builder calls, such as `CoroutineScope.launch()`, into separate functions.

Consider the following example:

```
suspend fun main() {
    coroutineScope { // this: CoroutineScope
        // Calls CoroutineScope.launch() where CoroutineScope is the receiver
        this.launch { println("1") }
        this.launch { println("2") }
    }
}
```

You can also write `this.launch` without the explicit `this` expression, as `launch`. These examples use explicit `this` expressions to highlight that it's an extension function on `CoroutineScope`.

For more information on how lambdas with receivers work in Kotlin, see Function literals with receiver.

The `coroutineScope()` function takes a lambda with a `CoroutineScope` receiver. Inside this lambda, the implicit receiver is a `CoroutineScope`, so builder functions like `CoroutineScope.launch()` and `CoroutineScope.async()` resolve as extension functions on that receiver.

To extract the coroutine builders into another function, that function must declare a `CoroutineScope` receiver, otherwise a compilation error occurs:

```
import kotlinx.coroutines.*
suspend fun main() {
    coroutineScope {
        launchAll()
    }
}

fun CoroutineScope.launchAll() { // this: CoroutineScope
    // Calls .launch() on CoroutineScope
    this.launch { println("1") }
    this.launch { println("2") }
}
/* -- Calling launch without declaring CoroutineScope as the receiver results in a compilation error -
-

fun launchAll() {
    // Compilation error: this is not defined
    this.launch { println("1") }
    this.launch { println("2") }
}
 */
```

In this example, the `launchAll()` function doesn't need the `suspend` keyword, because it only starts the coroutines in the current `CoroutineScope` and then returns immediately. Only mark functions with `suspend` when it makes sense for them to pause and resume before returning.

Coroutine builder functions

A coroutine builder function is a function that accepts a `suspend` lambda that defines a coroutine to run. Here are some examples:

- `CoroutineScope.launch()`
- `CoroutineScope.async()`
- `runBlocking()`

- `withContext()`
- `coroutineScope()`

Coroutine builder functions require a `CoroutineScope` to run in. This can be an existing scope or one you create with helper functions such as `coroutineScope()`, `runBlocking()`, or `withContext()`. Each builder defines how the coroutine starts and how you interact with its result.

`CoroutineScope.launch()`

The `CoroutineScope.launch()` coroutine builder function is an extension function on `CoroutineScope`. It starts a new coroutine without blocking the rest of the scope, inside an existing coroutine scope.

Use `CoroutineScope.launch()` to run a task alongside other work when the result isn't needed or you don't want to wait for it:

```
// Imports the kotlin.time.Duration to enable expressing duration in milliseconds
import kotlin.time.Duration.Companion.milliseconds

import kotlinx.coroutines.*

suspend fun main() {
    withContext(Dispatchers.Default) {
        performBackgroundWork()
    }
}

suspend fun performBackgroundWork() = coroutineScope { // this: CoroutineScope
    // Starts a coroutine that runs without blocking the scope
    this.launch {
        // Suspends to simulate background work
        delay(100.milliseconds)
        println("Sending notification in background")
    }

    // Main coroutine continues while a previous one suspends
    println("Scope continues")
}
```

After running this example, you can see that the `main()` function isn't blocked by `CoroutineScope.launch()` and keeps running other code while the coroutine works in the background.

> The `CoroutineScope.launch()` function returns a `Job` handle. Use this handle to wait for the launched coroutine to complete. For more information, see Cancellation and timeouts.

`CoroutineScope.async()`

The `CoroutineScope.async()` coroutine builder function is an extension function on `CoroutineScope`. It starts a concurrent computation inside an existing coroutine scope and returns a `Deferred` handle that represents an eventual result. Use the `.await()` function to suspend the code until the result is ready:

```
// Imports the kotlin.time.Duration to enable expressing duration in milliseconds
import kotlin.time.Duration.Companion.milliseconds

import kotlinx.coroutines.*

suspend fun main() = withContext(Dispatchers.Default) { // this: CoroutineScope
    // Starts downloading the first page
    val firstPage = this.async {
        delay(50.milliseconds)
        "First page"
    }

    // Starts downloading the second page in parallel
    val secondPage = this.async {
        delay(100.milliseconds)
        "Second page"
    }

    // Awaits both results and compares them
    val pagesAreEqual = firstPage.await() == secondPage.await()
    println("Pages are equal: $pagesAreEqual")
}
```

`runBlocking()`

The `runBlocking()` coroutine builder function creates a coroutine scope and blocks the current thread until the coroutines launched in that scope finish.

Use `runBlocking()` only when there is no other option to call suspending code from non-suspending code:

```
import kotlin.time.Duration.Companion.milliseconds
import kotlinx.coroutines.*

// A third-party interface you can't change
interface Repository {
    fun readItem(): Int
}

object MyRepository : Repository {
    override fun readItem(): Int {
        // Bridges to a suspending function
        return runBlocking {
            myReadItem()
        }
    }
}

suspend fun myReadItem(): Int {
    delay(100.milliseconds)
    return 4
}
```

Coroutine dispatchers

A *coroutine dispatcher* controls which thread or thread pool coroutines use for their execution. Coroutines aren't always tied to a single thread. They can pause on one thread and resume on another, depending on the dispatcher. This lets you run many coroutines at the same time without allocating a separate thread for every coroutine.

Even though coroutines can suspend and resume on different threads, values written before the coroutine suspends are still guaranteed to be available within the same coroutine when it resumes.

A dispatcher works together with the coroutine scope to define when coroutines run and where they run. While the coroutine scope controls the coroutine's lifecycle, the dispatcher controls which threads are used for execution.

You don't have to specify a dispatcher for every coroutine. By default, coroutines inherit the dispatcher from their parent scope. You can specify a dispatcher to run a coroutine in a different context.

If the coroutine context doesn't include a dispatcher, coroutine builders use `Dispatchers.Default`.

The `kotlinx.coroutines` library includes different dispatchers for different use cases. For example, `Dispatchers.Default` runs coroutines on a shared pool of threads, performing work in the background, separate from the main thread. This makes it an ideal choice for CPU-intensive operations like data processing.

To specify a dispatcher for a coroutine builder like `CoroutineScope.launch()`, pass it as an argument:

```
suspend fun runWithDispatcher() = coroutineScope { // this: CoroutineScope
    this.launch(Dispatchers.Default) {
        println("Running on ${Thread.currentThread().name}")
    }
}
```

Alternatively, you can use a `withContext()` block to run all code in it on a specified dispatcher:

```
// Imports the kotlin.time.Duration to enable expressing duration in milliseconds
import kotlin.time.Duration.Companion.milliseconds

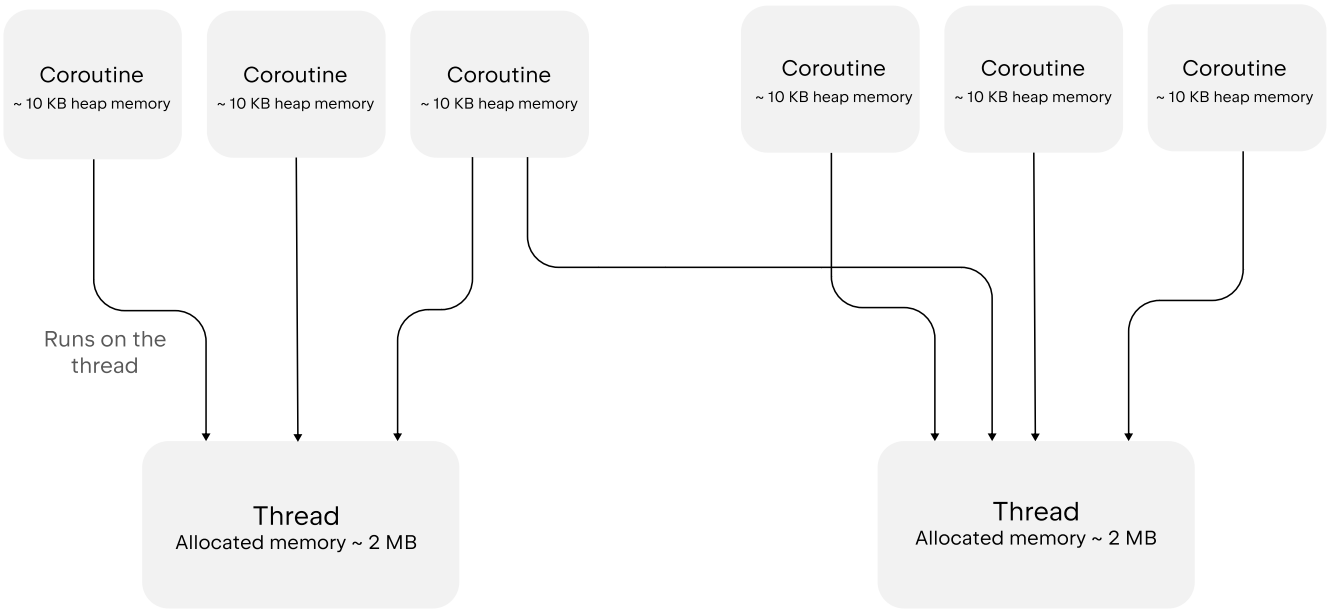
import kotlinx.coroutines.*

suspend fun main() = withContext(Dispatchers.Default) { // this: CoroutineScope
    println("Running withContext block on ${Thread.currentThread().name}")

    val one = this.async {
        println("First calculation starting on ${Thread.currentThread().name}")
        val sum = (1L..500_000L).sum()
        delay(200L)
        println("First calculation done on ${Thread.currentThread().name}")
        sum
    }

    val two = this.async {
        println("Second calculation starting on ${Thread.currentThread().name}")
        val sum = (500_001L..1_000_000L).sum()
        println("Second calculation done on ${Thread.currentThread().name}")
        sum
    }

    // Waits for both calculations and prints the result
    println("Combined total: ${one.await() + two.await()}")
}
```



To learn more about coroutine dispatchers and their uses, including other dispatchers like `Dispatchers.IO` and `Dispatchers.Main`, see Coroutine context and dispatchers.

Comparing coroutines and JVM threads

While coroutines are suspendable computations that run code concurrently like threads on the JVM, they work differently under the hood.

A *thread* is managed by the operating system. Threads can run tasks in parallel on multiple CPU cores and represent a standard approach to concurrency on the JVM. When you create a thread, the operating system allocates memory for its stack and uses the kernel to switch between threads. This makes threads powerful but also resource-intensive. Each thread usually needs a few megabytes of memory, and typically the JVM can only handle a few thousand threads at once.

On the other hand, a coroutine isn't bound to a specific thread. It can suspend on one thread and resume on another, so many coroutines can share the same thread pool. When a coroutine suspends, the thread isn't blocked and remains free to run other tasks. This makes coroutines much lighter than threads and allows running millions of them in one process without exhausting system resources.

Comparing coroutines and threads

Let's look at an example where 50,000 coroutines each wait five seconds and then print a period (`.`):

```
import kotlin.time.Duration.Companion.seconds
import kotlinx.coroutines.*

suspend fun main() {
    withContext(Dispatchers.Default) {
        // Launches 50,000 coroutines that each wait five seconds, then print a period
        printPeriods()
    }
}

suspend fun printPeriods() = coroutineScope { // this: CoroutineScope
    // Launches 50,000 coroutines that each wait five seconds, then print a period
    repeat(50_000) {
        this.launch {
            delay(5.seconds)
            print(".")
        }
    }
}
```

Now let's look at the same example using JVM threads:

```
import kotlin.concurrent.thread

fun main() {
    repeat(50_000) {
        thread {
            Thread.sleep(5000L)
            print(".")
        }
    }
}
```

Running this version uses much more memory because each thread needs its own memory stack. For 50,000 threads, that can be up to 100 GB, compared to roughly 500 MB for the same number of coroutines.

Depending on your operating system, JDK version, and settings, the JVM thread version may throw an out-of-memory error or slow down thread creation to avoid running too many threads at once.

What's next

- Discover more about combining suspending functions in Composing suspending functions.
- Learn how to cancel coroutines and handle timeouts in Cancellation and timeouts.
- Dive deeper into coroutine execution and thread management in Coroutine context and dispatchers.
- Learn how to return multiple asynchronously computed values in Flows.

Cancellation and timeouts

Cancellation lets you request to stop a coroutine before it completes. It stops work that's no longer needed, such as when a user closes a window or navigates away in a user interface while a coroutine is still running.

You can use cancellation to release resources early and to stop a coroutine from accessing objects past their disposal. You can also use it to stop long-running coroutines that perform repeated work, such as:

- Sending heartbeats.

- Running scheduled tasks.
- Updating a state to reflect the newest reading, such as in a clock UI.

Cancellation works through the `Job` handle, which represents the lifecycle of a coroutine and its parent-child relationships. `Job` allows you to check whether the coroutine is active and allows you to cancel it, along with its children, as defined by structured concurrency.

Cancel coroutines

A coroutine is canceled when the `cancel()` function is invoked on its `Job` handle. Coroutine builder functions such as `.launch()` return a `Job`. The `.async()` function returns a `Deferred`, which implements `Job` and supports the same cancellation behavior.

You can call the `cancel()` function manually, or it can be invoked automatically through cancellation propagation when a parent coroutine is canceled.

When a coroutine is canceled, it throws a `CancellationException` the next time it checks for cancellation. Suspending functions in the `kotlinx.coroutines` library, such as the `delay()` function, check for cancellation when they suspend.

You can use the `awaitCancellation()` function to suspend a coroutine until it's canceled. It's equivalent to calling `delay(Duration.INFINITE)`.

> For more information about how and when coroutines check for cancellation, see Suspension points and cancellation.

Here's an example of how to manually cancel a coroutine:

```
import kotlinx.coroutines.*

suspend fun main() {
withContext(Dispatchers.Default) {
    // Used as a signal that the coroutine has started running
    val childStarted = CompletableDeferred<Unit>()

    val childJob: Job = launch {
        println("The coroutine has started")

        // Completes the CompletableDeferred,
        // signaling that the coroutine has started running
        childStarted.complete(Unit)
        try {
            // Suspends indefinitely
            // This call will never return unless the coroutine is canceled
            awaitCancellation()
        } catch (e: CancellationException) {
            println("The coroutine was canceled: $e")

            // Always rethrow cancellation exceptions!
            throw e
        }
        println("This line will never be executed")
    }

    // Waits for the coroutine to start before canceling it
    childStarted.await()

    // Cancels the coroutine,
    // so awaitCancellation() throws a CancellationException
    childJob.cancel()
}
// Coroutine builders such as withContext() or coroutineScope()
// wait for all child coroutines to complete,
// even when the children are canceled
println("All coroutines have completed")
}
```

In this example, `CompletableDeferred` is used as a signal that the coroutine has started running. The coroutine calls `complete()` when it starts executing, and `await()` only returns once that `CompletableDeferred` is completed. You don't need this check to cancel a coroutine. It's included here to make the example reproducible by ensuring that the coroutine starts and prints its messages before it's canceled.

Because `Deferred` implements `Job`, cancellation works the same way for coroutines created by the `async()` coroutine builder function:

```
val deferred = async { /* ... */ }
deferred.cancel()
```

Catching `CancellationException` can break the cancellation propagation. If you must catch it, rethrow it to let the cancellation propagate correctly through the coroutine hierarchy.

For more information, see Coroutine exceptions handling.

Cancellation propagation

Structured concurrency ensures that canceling a coroutine also cancels all of its children. This prevents child coroutines from continuing their work after their parent coroutine is canceled.

Here's an example:

```
import kotlinx.coroutines.*

suspend fun main() {
    withContext(Dispatchers.Default) {
// Used as a signal that the child coroutines have been launched
val childrenLaunched = CompletableDeferred<Unit>()

// Launches two child coroutines
val parentJob = launch {
    launch {
        println("Child coroutine 1 has started running")
        try {
            awaitCancellation()
        } finally {
            println("Child coroutine 1 has been canceled")
        }
    }
    launch {
        println("Child coroutine 2 has started running")
        try {
            awaitCancellation()
        } finally {
            println("Child coroutine 2 has been canceled")
        }
    }
    // Completes the CompletableDeferred,
    // signaling that the child coroutines have been launched
    childrenLaunched.complete(Unit)
}
// Waits for the parent coroutine to signal that it has launched
// all of its children
childrenLaunched.await()

// Cancels the parent coroutine, which cancels all its children
parentJob.cancel()
    }
}
```

In this example, each child coroutine uses a `finally` block, so the code inside it runs when the coroutine is canceled. Here, `CompletableDeferred` signals that the child coroutines are launched before they're canceled, but it doesn't guarantee that they start running. If they're canceled first, nothing is printed.

Make coroutines react to cancellation

In Kotlin, coroutine cancellation is *cooperative*. Coroutines react to cancellation only when they cooperate by suspending or checking for cancellation explicitly.

In this section, you can learn how adding suspension points, such as calls to the yield() function, lets coroutines react to cancellation.

Suspension points and cancellation

When a coroutine is canceled, it continues running until it reaches a point in the code where it may suspend, also known as a *suspension point*. If the coroutine suspends there, the suspending function checks whether it has been canceled. If it has, the coroutine stops and throws `CancellationException`.

A call to a `suspend` function is a suspension point, but it doesn't always suspend. For example, when awaiting a `Deferred` result, the coroutine only suspends if that `Deferred` isn't completed yet.

Here's an example using common suspending functions that suspend, enabling the coroutine to check and stop when it's canceled:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.sync.Mutex
import kotlinx.coroutines.channels.Channel
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration

suspend fun main() {
withContext(Dispatchers.Default) {
    val childJobs = listOf(
        launch {
            // Suspends until canceled
            awaitCancellation()
        },
        launch {
            // Suspends until canceled
            delay(Duration.INFINITE)
        },
        launch {
            val channel = Channel<Int>()
            // Suspends while waiting for a value that's never sent
            channel.receive()
        },
        launch {
            val deferred = CompletableDeferred<Int>()
            // Suspends while waiting for a value that's never completed
            deferred.await()
        },
        launch {
            val mutex = Mutex(locked = true)
            // Suspends while waiting for a mutex that remains locked indefinitely
            mutex.lock()
        }
    )

    // Gives the child coroutines time to start and suspend
    delay(100.milliseconds)

    // Cancels all child coroutines
    childJobs.forEach { it.cancel() }
}
println("All child jobs completed!")
}
```

All suspending functions in the `kotlinx.coroutines` library cooperate with cancellation because they use `suspendCancellableCoroutine()` internally, which checks for cancellation when the coroutine suspends. In contrast, custom suspending functions that use `suspendCoroutine()` don't react to cancellation.

The `yield()` suspending function

If a coroutine doesn't suspend, other coroutines can't run on the same thread until it completes. As a result, coroutines that don't suspend run sequentially on that thread. If a coroutine doesn't suspend for a long time, it also doesn't stop when it's canceled.

In CPU-intensive computations and other code that runs for a long time without suspending, call the `yield()` function periodically. This function releases the current thread and gives other coroutines a chance to run on it. It also ensures that the coroutine checks for cancellation regularly. If the coroutine is canceled, the `yield()` function throws a `CancellationException`.

Comparison of coroutine cancellation handling without checks, with ensureActive() or isActive, and with yield()

Here's an example:

```
import kotlinx.coroutines.*

fun main() {
// runBlocking uses the current thread for running all coroutines
runBlocking {
    val coroutineCount = 5
    repeat(coroutineCount) { coroutineIndex ->
        launch {
            val id = coroutineIndex + 1
            repeat(5) { iterationIndex ->
                val iteration = iterationIndex + 1
                // Suspends temporarily to give other coroutines a chance to run
                // Without this, the coroutines run sequentially
                yield()
                // Prints the coroutine index and iteration index
                println("$id * $iteration = ${id * iteration}")
            }
        }
    }
}
}
```

In this example, each coroutine uses `yield()` to let other coroutines run between iterations.

Check for cancellation explicitly

You can check for cancellation explicitly, which lets long-running code react to cancellation without suspending. A long-running coroutine that doesn't suspend can prevent other coroutines on the same thread from running until it completes. Unless this behavior is intentional for your use case, use the `yield()` function instead.

Depending on the API, the check either returns a Boolean value or throws an exception:

- The `isActive` property returns `false` when the coroutine is canceled.
- The `ensureActive()` function throws a `CancellationException` when the coroutine is canceled.

Interrupt blocking code when coroutines are canceled

On the JVM, some blocking functions, such as `Thread.sleep()` or `BlockingQueue.take()`, can block the current thread. These blocking functions can be interrupted, which stops them prematurely. However, when you call them from a coroutine, cancellation doesn't interrupt the thread.

To interrupt the thread when canceling a coroutine, wrap the blocking code in the `runInterruptible()` function:

```
import kotlinx.coroutines.*

suspend fun main() {
withContext(Dispatchers.Default) {
    val childStarted = CompletableDeferred<Unit>()
    val childJob = launch {
        try {
            // Cancellation triggers a thread interruption
            runInterruptible {
                childStarted.complete(Unit)
                try {
                    // Blocks the current thread for a very long time
                    Thread.sleep(Long.MAX_VALUE)
                } catch (e: InterruptedException) {
                    println("Thread interrupted (Java): $e")
                    throw e
                }
            }
        } catch (e: CancellationException) {
            println("Coroutine canceled (Kotlin): $e")
            throw e
        }
    }
    childStarted.await()

    // Cancels the coroutine and interrupts the thread executing Thread.sleep()
    childJob.cancel()
}
}
```

Handle values safely when canceling coroutines

When a suspended coroutine is canceled, it resumes with a `CancellationException` instead of returning any values, even if those values are already available. This behavior is called *prompt cancellation*. It prevents your code from continuing in a canceled coroutine's scope, such as updating a screen that's already closed.

Here's an example:

```
// Defines a coroutine scope that uses the UI thread
class ScreenWithButtons(private val scope: CoroutineScope) {
    fun loadAndUpdateButtons(filename: String) {
        scope.launch {
            // withContext() checks for cancellation before entering the block
            // and after the block returns
            val buttonNames = withContext(Dispatchers.IO) {
                // This is a blocking call that doesn't react to cancellation
                readLines(filename)
            }

            // It's safe to call updateUi()
            // because withContext() doesn't return if the coroutine is canceled,
            // and no code running on the UI thread can dispose of the buttons before this call
            updateUi(buttonNames)
        }
    }

    // Call this function only from the UI thread because it accesses the buttons
    // Throws an exception if called after the buttons are disposed
    private fun updateUi(buttonNames: List<String>) {
        // Placeholder code that updates the buttons with specified names
    }

    // Call this function only from the UI thread
    fun leaveScreen() {
        // Cancels the scope when leaving the screen
        // You can no longer update the UI
        scope.cancel()
    }
}

// UI controller code
setHandler(Event.ScreenClosed) {
    // Runs on the UI thread
    screenWithButtons.leaveScreen()
    buttons.dispose()
}
```

In this example, `withContext(Dispatchers.IO)` cooperates with cancellation and prevents `updateUi()` from running if the `leaveScreen()` function cancels the coroutine before `withContext(Dispatchers.IO)` returns the button names.

While prompt cancellation prevents using values after they're no longer valid, it can also stop your code while an important value is still in use, which might lead to losing that value. This can happen when a coroutine receives a value, such as an `AutoCloseable` resource, but is canceled before it can reach the part of the code that closes it. To prevent this, keep cleanup logic in a place that's guaranteed to run even when the coroutine receiving the value is canceled.

Here's an example:

```
import java.nio.file.*
import java.nio.charset.*
import kotlinx.coroutines.*
import java.io.*

// Uses a scope that runs its coroutines on the UI thread
class ScreenWithFileContents(private val scope: CoroutineScope) {
    fun displayFile(path: Path) {
        scope.launch {
            // Stores the reader in a variable, so the finally block can close it
            var reader: BufferedReader? = null

            try {
                withContext(Dispatchers.IO) {
                    reader = Files.newBufferedReader(
                        path, Charset.forName("US-ASCII")
                    )
                }
                // Uses the stored reader after withContext() completes
                updateUi(reader!!)
            } finally {
                // Ensures the reader is closed even when the coroutine is canceled
                reader?.close()
            }
        }
    }

    private suspend fun updateUi(reader: BufferedReader) {
        // Shows the file contents
        while (true) {
            val line = withContext(Dispatchers.IO) {
                reader.readLine()
            }
            if (line == null)
                break
            addOneLineToUi(line)
        }
    }

    private fun addOneLineToUi(line: String) {
        // Placeholder for code that adds one line to the UI
    }

    // Only callable from the UI thread
    fun leaveScreen() {
        // Cancels the scope and prevents its coroutines from updating the UI
        scope.cancel()
    }
}
```

In this example, storing the `BufferedReader` in a variable and closing it in the `finally` block ensures the resource is released even if the coroutine is canceled.

Run non-cancelable blocks

You can prevent cancellation from affecting certain parts of a coroutine. To do so, pass `NonCancellable` as an argument to the `withContext()` coroutine builder function.

Avoid using `NonCancellable` with other coroutine builders like `.launch()` or `.async()`. Doing so disrupts structured concurrency by breaking the parent-child relationship.

`NonCancellable` is useful when you need to ensure that certain operations, such as closing resources with a suspending `close()` function, complete even if the coroutine is canceled before they finish.

Here's an example:

```
import kotlinx.coroutines.*
import kotlin.time.Duration.Companion.milliseconds

val serviceStarted = CompletableDeferred<Unit>()

fun startService() {
    println("Starting the service...")
    serviceStarted.complete(Unit)
}

suspend fun shutdownServiceAndWait() {
    println("Shutting down...")
    delay(100.milliseconds)
    println("Successfully shut down!")
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        val childJob = launch {
            startService()
            try {
                awaitCancellation()
            } finally {
                withContext(NonCancellable) {
                    // Without withContext(NonCancellable),
                    // this function doesn't complete because the coroutine is canceled
                    shutdownServiceAndWait()
                }
            }
        }
        serviceStarted.await()
        childJob.cancel()
    }
    println("Exiting the program")
}
```

Timeout

A timeout allows you to automatically cancel a coroutine after a specified duration. You can use it to stop operations that take too long.

For example, if a request to download a picture from a server times out, you can retry or fallback to the local cache.

To specify a timeout, use the `withTimeoutOrNull()` function with a `Duration`:

```
import kotlinx.coroutines.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun slowOperation(): String {
    try {
        delay(300.milliseconds)
        return "A"
    } catch (e: CancellationException) {
        println("The slow operation has been canceled: $e")
        throw e
    }
}

suspend fun fastOperation(): String {
    try {
        delay(15.milliseconds)
        return "B"
    } catch (e: CancellationException) {
        println("The fast operation has been canceled: $e")
        throw e
    }
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        val slow = withTimeoutOrNull(100.milliseconds) {
            slowOperation()
        }
        println("The slow operation finished with $slow")
        val fast = withTimeoutOrNull(100.milliseconds) {
            fastOperation()
        }
        println("The fast operation finished with $fast")
    }
}
```

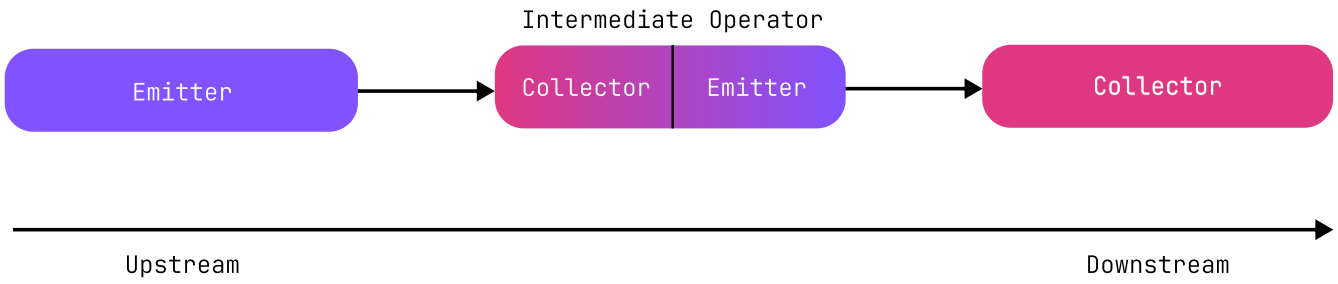
If the timeout exceeds the specified `Duration`, `withTimeoutOrNull()` returns `null`.

Flows

A flow represents a sequential stream of values that can be produced asynchronously. Unlike a suspending function, which returns one value, you can use flows to work with multiple sequential values over time.

You can use flows to create *flow pipelines* that load data progressively, react to event streams, and model subscription-style APIs.

A flow pipeline is a sequence of operations that involves the following roles:



- **Emitter**: produces values.
- **Intermediate operators (optional)**: consume values from a flow, apply an operation to them, and return another flow.
- **Collector**: consumes values from a flow.

Here's a simple example that shows how these pipeline roles work together:

```kotlin
import kotlinx.coroutines.flow.*

suspend fun main() {
    // The emitter produces values
    flowOf(0x4B, 0x6F, 0x74, 0x6C, 0x69, 0x6E)
        // The intermediate operator consumes values,
        // applies an operation, and returns another flow
        .map { value -> value.toChar() }
        // The collector consumes the transformed values
        .collect { updatedValue ->
            println("Say '$updatedValue'!")
        }
}
```

In a flow, values move from an emitter toward a collector, from *upstream* to *downstream*. Intermediate operators collect an upstream flow, apply an operation to its values, and return a new downstream flow. That downstream flow can become the upstream flow for the next collector.

Parts of a flow: emitter, intermediate operator (optional), collector. Values move from upstream to downstream.

Kotlin provides the following flow types:

- **Cold flows** start producing values when collected. Each collector triggers a new, independent execution of the flow.
- **Hot flows** emit values independently of collectors and share the same stream of values with all collectors.

> You can use the Turbine library to test Kotlin flows. It simplifies collecting and asserting flow emissions in unit tests, including completion and failure cases.

Cold flows

Like sequences, cold flows are lazy.

The code block of a cold flow builder doesn't run until a collector collects it. Each new collector starts a new execution of the flow.

Create a cold flow

To create a cold flow, use the `flow()` builder function. Inside its block, use the `emit()` function to emit values to collectors:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

fun main() {
    // Creates a flow
    val pageFlow = flow {
        for (page in 1..3) {
            println("Loading page $page...")

            // Emits each page as it is loaded
            emit("Page $page")
        }
    }
    println("Creating a cold flow doesn't run it!")
}
```

In this example, the `flow()` builder function returns a `Flow<T>`, but it doesn't start executing its block. A cold flow is like a recipe: it defines how to produce values, but it only starts producing values when you collect it.

You can also create cold flows with the following functions:

- `flowOf()`: creates a flow from provided values.
- `.asFlow()`: converts an existing iterable, such as a range, into a flow.

Here's an example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

fun main() {
    // Creates a flow from provided values
    val predefinedPageFlow = flowOf("Page 1", "Page 2", "Page 3")
    // Creates a flow from a range
    val generatedPageFlow = (1..3).asFlow()
}
```

Collect a cold flow

To collect a cold flow, use the `collect()` function, which triggers the emissions from the upstream flow. If you pass a lambda to `collect()`, it receives each emitted value:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() {
    withContext(Dispatchers.Default) {
        val pageFlow = flow {
            for (page in 1..3) {
                println("Loading page $page...")
                emit("Page $page")
            }
        }
        // Collects the flow with a lambda that receives each emitted page
        pageFlow.collect { page ->
            println("Processing $page...")
            delay(100.milliseconds)
            println("Done processing $page.")
        }
    }
}
```

Each call to `collect()` runs the entire cold flow from the beginning. If multiple collectors collect the same cold flow, each collector triggers its own collection:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() {
    val pageFlow = flow {
        // Reads the name of the current coroutine
        val coroutineName = currentCoroutineContext()[CoroutineName]?.name

        println("Starting emissions in $coroutineName")
        for (page in 1..3) {
            println("Loading page $page in $coroutineName")
            emit("Page $page")
        }
        println("Done emitting in $coroutineName")
    }

    withContext(Dispatchers.Default) {
        // Launches a collector that processes each page slowly
        launch(CoroutineName("a slow coroutine")) {
            pageFlow.collect {
                println("Processing $it slowly")
                delay(100.milliseconds)
                println("Done processing $it slowly")
            }
        }

        // Launches a collector that processes each page quickly
        launch(CoroutineName("a fast coroutine")) {
            pageFlow.collect {
                println("Processing $it quickly")
                delay(10.milliseconds)
                println("Done processing $it quickly")
            }
        }
    }
}
```

In this example, `CoroutineName` adds a name to each coroutine. You can use `CoroutineName` for debugging. Here, it helps show which collector runs each collection.

Intermediate flow operators

Intermediate operators apply operations to an upstream flow and return a new downstream flow. They are cold, so the returned flow doesn't start processing values until it's collected, even when the upstream flow is hot.

The kotlinx.coroutines library offers a wide range of intermediate flow operators for transforming and processing flows. You can also define custom operators yourself when you need behavior that the built-in operators don't provide.

Here's an example of a simplified custom `.map()` operator that applies a transformation to each emitted value:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom implementation of the default .map() operator
fun <T, R> Flow<T>.myMap(transform: suspend (value: T) -> R): Flow<R> = flow {
    // Collects values from the upstream flow
    this@myMap.collect { value ->
        // Transforms each collected value and emits the result
        emit(transform(value))
    }
}

suspend fun main() {
    // Creates a flow, applies the custom map operator, and collects the transformed values
    flowOf(1, 2, 3).myMap { 2 * it }.collect {
        println("Collecting $it")
    }
}
```

Call suspending functions inside a flow builder

Unlike in sequences, you can call suspending functions inside a `flow()` builder function:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun loadPage(): Int {
    delay(100)
    return 3
}

suspend fun main() {
    flow {
        emit(loadPage())
    }.collect {
        println(it)
        // 3
    }
}
```

However, a `flow()` builder function must emit values from the same coroutine context where it runs. You can't start another coroutine that calls `emit()` in its block, and you can't change the coroutine context with `withContext()`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    // This fails with an exception!
    flow {
        // Changes the coroutine context with withContext()
        withContext(Dispatchers.IO) {
            emit('a')
        }
    }.collect {
        println("This never prints")
    }
}
```

This restriction applies to the `flow()` builder function.

If you need the upstream flow to run in a different coroutine context, you can change it with the `.flowOn()` operator.

Alternatively, you can use `channelFlow()` to emit values from multiple coroutines.

Change the coroutine context of a cold flow with `.flowOn()`

By default, a cold flow runs in the same coroutine context as the collector.

If you want the flow to run in a different coroutine context, use the `.flowOn()` operator. This operator is *context-preserving*. It changes only the coroutine context of the upstream flow while keeping the downstream flow in the caller's context.

Here's an example of a cold flow that emits values in one coroutine context and collects them in another:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    withContext(Dispatchers.Default + CoroutineName("downstream")) {
        flow {
            val coroutineName = currentCoroutineContext()[CoroutineName]?.name

            // Emits in the coroutine context applied with .flowOn()
            println("Emitting '1' in $coroutineName")
            // Emitting '1' in upstream
            emit(1)

        // Changes the coroutine context of the upstream flow
        }.flowOn(Dispatchers.IO + CoroutineName("upstream"))
            .collect {
            val coroutineName = currentCoroutineContext()[CoroutineName]?.name

            // Collects in the caller's coroutine context
            println("Collecting '$it' in $coroutineName")
            // Collecting '1' in downstream
        }
    }
}
```

Handle exceptions in flows

Both emitters and collectors can throw exceptions.

If you don't handle an exception during flow collection, it propagates upstream from the collector and is thrown to the caller of the `collect()` function.

You can handle such exceptions by wrapping the `collect()` function in a `try-catch` block, for example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

class MyFlowException(message: String) : Exception(message)

suspend fun main() {
    val myFlow = flow {
        try {
            // The emit() function calls the lambda passed to collect()
            emit('a')
        } catch (e: MyFlowException) {
            println("Collector threw $e")

            // Rethrows the downstream exception
            throw e
        }
    }
    // Wraps flow collection in try-catch
    try {
        myFlow.collect {
            // Throws an exception from the collect() lambda
            throw MyFlowException("Can't process '$it'!")
        }
    } catch (e: MyFlowException) {
        println("Flow collection failed with $e")
        // Rethrows the exception to the caller
        throw e
    }
}
```

In this example, the collector throws an exception when it receives a value from the `emit()` function. The `flow()` builder function catches this downstream exception.

When you catch an exception thrown by the collector inside a flow builder function, rethrow it. This preserves exception transparency and lets the caller of `collect()` handle the exception.

Use the `.catch()` operator to handle upstream exceptions

To handle exceptions before they reach the collector, use the `.catch()` operator.

You can use the `.catch()` operator to handle exceptions from the upstream flow, for example by using the `emit()` function to emit a fallback value downstream:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    flow {
        emit("a")
        emit("b")

        // Throws an exception from the upstream flow
        throw UnsupportedOperationException(
            "I am tired of listing letters"
        )
    }.catch { upstreamException ->
        println("Upstream completed with $upstreamException!")

        // Emits a fallback value downstream
        emit("Upstream terminated with an exception!")
    }.collect {
        println("Got '$it'")
    }
}
```

In this example, the upstream flow emits values before throwing an exception. The `.catch()` operator handles the exception and emits `"Upstream terminated with an exception!"` as a fallback value.

When a flow is expected to throw some exceptions during normal operation, handle the recoverable exceptions in `.catch()` and rethrow any unexpected exceptions.

Here's an example where a flow loads data and reports its progress:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

sealed interface LoadingState {
    sealed interface Terminal: LoadingState
    object Started: LoadingState
    data class Percentage(val percents: Int): LoadingState
    object Failed: Terminal
    object Done: Terminal
}

fun loadBlob(url: String) = flow {
    emit(LoadingState.Started)

    val failureChancePerStep = 1 - java.lang.Math.pow(0.99, 10.0)

    repeat(10) { step ->
        if (Random.nextDouble() < failureChancePerStep)
            throw IOException("Failed to load!")
        emit(LoadingState.Percentage((step + 1) * 10))
        delay(10.milliseconds)
    }
    emit(LoadingState.Done)
}.catch { e ->
    println("Loading data failed with $e")
    if (e is IOException) {
        // Handles an expected exception
        emit(LoadingState.Failed)
    } else {
        // Rethrows unexpected exceptions, so the collect() fails with them
        throw e
    }
}

suspend fun main() {
    loadBlob("https://example.com/").collect {
        println("Got '$it'")
    }
}
```

In this example, if loading fails with an expected exception, the `.catch()` operator uses the `emit()` function to emit a fallback state. For unexpected exceptions, rethrow them in the `.catch()` operator. This lets the caller of the `collect()` function receive exceptions that the flow doesn't handle.

The `.catch()` operator doesn't handle exceptions thrown by the collector. If the lambda passed to `collect()` throws an exception, handle it with a `try-catch` block around the `collect()` function:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    val myFlow = flow {
        for (char in listOf('a', 'o', '5', 'c')) {
            try {
                emit(char)
            } catch (e: IllegalArgumentException) {
                println("Collector doesn't support character '$char': $e")

                // Rethrows the downstream exception
                throw e
            }
        }
    }.catch { e ->
        // Doesn't run because the exception happens downstream
        println("Upstream threw an exception: $e")
    }

    try {
        myFlow.collect {
            require(!it.isDigit()) { "Digits are not allowed!" }
        }
    } catch (e: IllegalArgumentException) {
        // Handles the exception from the collect() lambda
        println("Flow collection failed with $e")
    }
}
```

Since the `collect()` lambda runs after `.catch()`, you can't use `.catch()` to handle exceptions thrown from it. To handle exceptions from code that runs for each emitted value with `.catch()`, place that code in .onEach() before `.catch()`.

The `.onEach()` operator runs its lambda before each value is emitted downstream. If `.catch()` handles an exception from `.onEach()`, the flow completes and doesn't emit the next value:

Here's an example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() {
    flowOf('a', 'o', '5', 'c')
        // Runs before each value is emitted downstream
        .onEach {
            require(!it.isDigit()) { "Digits are not allowed!" }
            println("Got '$it'")
        }
        .catch { e ->
            println("Caught an exception: $e")
        }
        .collect()
}
```

In this example, the `.onEach()` operator runs upstream from `.catch()`, so the `.catch()` operator handles the exception when the `require()` check fails for `'5'`.

Restart the upstream flow after an exception

Some operations may temporarily fail, such as a network request that loses its connection. For these cases, you can use the `.retry()` operator to restart the upstream flow after an exception.

The `.retry()` operator receives an exception and restarts collection when its lambda returns `true`, up to the specified number of retries. For example, `.retry(3)` retries the upstream flow up to three times after the first failed attempt.

If the lambda returns `false`, `.retry()` stops retrying and rethrows the exception.

> For more control over the retry logic, use the `.retryWhen()` operator. Like `.retry()`, it receives the exception, but it also receives the current attempt number and can emit values before retrying.

Here's an example that retries loading up to three times after an `IOException`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration.Companion.seconds

sealed interface LoadingState {
    sealed interface Terminal: LoadingState
    object Started: LoadingState
    data class Percentage(val percents: Int): LoadingState
    object Failed: Terminal
    object Done: Terminal
}

fun loadBlob(url: String) = flow {
    emit(LoadingState.Started)

    val failureChancePerStep = 1 - java.lang.Math.pow(0.99, 10.0)

    repeat(10) { step ->
        if (Random.nextDouble() < failureChancePerStep)
            throw IOException("Failed to load!")
        emit(LoadingState.Percentage((step + 1) * 10))
        delay(10.milliseconds)
    }
    emit(LoadingState.Done)
}.retry(3) { e ->
    if (e is IOException) {
        // This is an expected error
        // Waits for one second before retrying
        delay(1.seconds)
        true
    } else {
        // Stops retrying and rethrows unexpected exceptions
        false
    }
}

suspend fun main() {
    loadBlob("https://example.org/").collect {
        println("Got $it")
    }
}
```

Flow cancellation

Flow cancellation stops collection when the result is no longer needed, such as when a request times out.

Flow collection is tied to the coroutine that calls the `collect()` function. When that coroutine is canceled, the collection stops, and the upstream flow is canceled too.

To cancel flow collection, call the `cancel()` function on the `Job` of the collecting coroutine:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

val myFlow = flow {
    var i = 0
    try {
        while (true) {
            println("Emitting $i")
            emit(i)
            println("Emitted $i")
            ++i
            delay(10.milliseconds)
        }
    } catch (e: Throwable) {
        println("Upstream finished with $e")
        throw e
    }
}

suspend fun main() {
    coroutineScope {
        val job = launch {
            try {
                myFlow.collect {
                    println("Processing $it")
                    delay(5.milliseconds)
                }
            } catch (e: Throwable) {
                println("Collection finished with $e")
                throw e
            }
        }
        delay(100.milliseconds)

        // Cancels the coroutine that collects the flow
        job.cancel()
    }
}
```

The collector can also cancel the upstream flow while the collecting coroutine stays active. To do this, throw a `CancellationException` from the collector.

The `.take()` operator uses this behavior to stop collecting after a fixed number of values. For example, `.take(3)` collects only the first three values from the upstream flow, then cancels it.

Here's an example that uses a simplified version of the `.take()` operator:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

// Defines a simplified version of the default .take() operator
fun <T> Flow<T>.myTake(count: Int): Flow<T> = flow {
    require(count > 0)
    val cancellationException = CancellationException()
    var elementsRemaining = count
    try {
        this@myTake.collect {
            emit(it)
            --elementsRemaining
            if (elementsRemaining == 0) {
                // Cancels the upstream flow after the requested number of values
                throw cancellationException
            }
        }
    } catch (e: Throwable) {
        if (e === cancellationException) {
            // Handles the CancellationException used to cancel the upstream flow
            // Completes the flow after the set number of values in .myTake()
        } else {
            // Rethrows unexpected exceptions
            throw e
        }
    }
}

suspend fun main() {
    (0..1000).asFlow().myTake(3).collect {
        println("Got $it")
    }
}
```

In this example, the `.myTake()` function emits values from the upstream flow until all requested values are emitted. Then it throws a `CancellationException` to cancel the upstream flow.

Emit values concurrently with `channelFlow()`

The `flow()` builder function is simple and efficient for flows that emit values from one coroutine. If you want to emit values from multiple coroutines concurrently into the same flow, use the `channelFlow()` builder function. You can use it for concurrent work that reports results progressively, such as loading data from multiple sources.

The `channelFlow()` builder function creates a cold flow that uses a channel to send values from multiple coroutines. Inside the builder, use the `send()` function instead of the `emit()` function to produce values.

Here's an example that uses `channelFlow()` to collect two flows concurrently and re-emit their values with a simplified version of the `.merge()` operator:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

// Defines a simplified version of the default .merge() operator
fun <T> Flow<T>.myMerge(other: Flow<T>): Flow<T> = channelFlow {
    // CoroutineScope and SendChannel are available as receivers here
    // Launches a coroutine that collects the receiver flow
    launch {
        // Collects the receiver flow
        this@myMerge.collect {
            send(it)
        }
    }
    launch {
        // Launches a coroutine that collects the other flow
        other.collect {
            // Calls SendChannel.send
            send(it)
        }
    }
}

suspend fun main() {
    val flow1 = (0..3).asFlow().onEach { delay(20.milliseconds) }
    val flow2 = (6..9).asFlow().onEach { delay(50.milliseconds) }
    flow1.myMerge(flow2).collect { println(it) }
}
```

The `channelFlow()` builder function uses a buffered channel, allowing producers to send values ahead of the collector until the buffer is full. By default, the buffer can hold up to 64 values. When the buffer is full, producers suspend until the buffer has free space.

You can change the buffer capacity with the `.buffer()` operator. For example, `.buffer(12)` lets producers send up to 12 values ahead of the collector, while `.buffer(0)` removes the buffer, so each value is sent only when the collector can receive it.

Here's an example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() {
    val oneHundredNumbers = channelFlow {
        repeat(100) {
            println("Sending $it")
            send(it)
        }
    }

    // Uses the default buffer capacity
    oneHundredNumbers.collect {
        println("Processing $it")
        delay(10.milliseconds)
    }

    // Removes the buffer so sending and processing interleave from the start
    oneHundredNumbers.buffer(0).collect {
        println("Processing $it")
        delay(10.milliseconds)
    }
}
```

In this example, `oneHundredNumbers` flow uses the default buffer capacity, while `oneHundredNumbers.buffer(0)` flow has no buffer.

With the default buffer capacity, the producer sends values quickly until the buffer becomes full. After that, `send()` suspends until the buffer has free space, so `Sending` and `Processing` messages start to interleave.

With `.buffer(0)`, each `send()` call waits until the collector can receive the value, so `Sending` and `Processing` interleave from the start.

Hot flows

Hot flows are shared streams that emit values independently of collectors. They keep emitting values even when no collector is active, and multiple collectors can collect the same emissions from an already active stream instead of starting a new execution.

A collector of a hot flow is called a *subscriber*.

You can use hot flows when multiple parts of an application need to react to the same stream of updates, such as incoming chat messages, user actions, or UI state changes.

Kotlin provides two hot flow types:

- `SharedFlow` broadcasts values to multiple subscribers. Use it when you need to broadcast events that happen over time, such as messages or notifications.
- `StateFlow` is a specialized `SharedFlow` that always holds the latest state value. Use it when you need to represent state that changes over time, such as UI state.

Create a `SharedFlow`

`SharedFlow` is a hot flow that broadcasts emitted values that happen over time to its subscribers.

You can create a `SharedFlow` with the `MutableSharedFlow()` function.

A `MutableSharedFlow` exposes functions for emitting values. If you expose it directly, code outside the class can emit values into the flow.

To prevent this, store the mutable flow in a private backing property and expose a read-only `SharedFlow` with the `.asSharedFlow()` function. To emit values to subscribers, use the `emit()` function on the `MutableSharedFlow`:

```
data class Message(
    val senderId: Int,
    val time: Instant,
    val text: String,
)

class Chatroom {
    // Stores the SharedFlow in a private backing property
    private val _messages = MutableSharedFlow<Message>()

    // Exposes a read-only SharedFlow to subscribers
    val messages: SharedFlow<Message>
        get() = _messages.asSharedFlow()

    suspend fun sendMessageToEveryone(message: Message) {
        // Emits the message to subscribers
        _messages.emit(message)
    }
}
```

Just like with cold flows, you can use the `collect()` function to collect values from a `SharedFlow`.

You can also configure a `SharedFlow` to immediately replay already emitted values to new subscribers. The replay cache works like a small history buffer, storing a fixed number of previous emissions.

To set how many previous emissions a new subscriber receives, use the `replay` parameter in `MutableSharedFlow()`:

```
// Sets the number of already emitted messages new subscribers receive on subscription
const val MESSAGES_TO_REMEMBER = 10

class Chatroom {
    private val _messages = MutableSharedFlow<Message>(

        // Replays the set amount of last emitted messages to new subscribers
        replay = MESSAGES_TO_REMEMBER
    )

    val messages: SharedFlow<Message>
        get() = _messages.asSharedFlow()

    suspend fun sendMessageToEveryone(message: Message) {
        // Emits the message to subscribers of the messages flow
        _messages.emit(message)
    }
}
```

Collecting a hot flow doesn't complete by itself, so you must cancel the collecting coroutines when you no longer need them.

A hot flow doesn't have a close or cancel operation. Canceling collection only stops the corresponding subscriber from collecting. To stop new emissions, cancel the coroutine or scope that produces values for the hot flow.

Let's look at an example that uses a `SharedFlow` to model a chat room, which sends each new message to active subscribers and replays recent messages to subscribers that join later:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.*

data class Message(
    val senderId: Int,
    val time: Instant,
    val text: String,
)

// Sets the number of already emitted messages that new subscribers receive on subscription
const val MESSAGES_TO_REMEMBER = 10

class Chatroom {
    // Stores the SharedFlow in a private backing property
    private val _messages = MutableSharedFlow<Message>(

        // Replays the set amount of last emitted messages to new subscribers
        replay = MESSAGES_TO_REMEMBER
    )

    // Exposes a read-only SharedFlow to subscribers
    val messages: SharedFlow<Message>
        get() = _messages.asSharedFlow()

    // Emits the message to subscribers
    suspend fun sendMessageToEveryone(message: Message) {
        _messages.emit(message)
    }
}

suspend fun main() {
    val nUsers = 3
    val chatroom = Chatroom()
    withContext(Dispatchers.Default) {
        // Starts a message reader for each user
        val messageReaders = List(nUsers) { userId ->
            // Starts collection before messages are emitted
            launch(start = CoroutineStart.UNDISPATCHED) {
                chatroom.messages.collect { message ->
                    println("User $userId received $message")
                }
            }
        }
        // Sends a greeting from each user
        repeat(nUsers) { userId ->
            chatroom.sendMessageToEveryone(
                Message(
                    userId,
                    Clock.System.now(),
                    "Hello from $userId!"
                )
            )
        }
        // Delays to make sure people have enough time to chat
        delay(100.milliseconds)
        // Cancels readers because SharedFlow collection doesn't finish by itself
        messageReaders.forEach { it.cancel() }
    }
```

```
}
```

In this example, `CoroutineStart.UNDISPATCHED` starts each collecting coroutine immediately.

This ensures that each coroutine reaches `collect()`, subscribes to `messages`, and suspends before `sendMessageToEveryone()` emits messages. Without it, a collecting coroutine might start later and miss earlier emissions if the replay cache is too small.

Experimental

Use explicit backing fields to expose hot flows

You can use explicit backing fields to expose a read-only `SharedFlow` while keeping a mutable backing field inside the class.

Explicit backing fields define the implementation type in the `field` declaration. Inside the class, the compiler smart casts the property to the backing field type, so you can call the `emit()` function without a separate private backing property.

> Explicit backing fields don't create the read-only wrapper that `.asSharedFlow()` provides. Use this pattern only when downcasting the exposed flow isn't a concern.

Here's an example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Clock
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.ExperimentalTime
import kotlin.time.Instant

data class Message(
    val senderId: Int,
    val time: Instant,
    val text: String,
)

const val MESSAGES_TO_REMEMBER = 10

class Chatroom {
    // Exposes a read-only SharedFlow with a mutable backing field
    val messages: SharedFlow<Message>
        field = MutableSharedFlow<Message>(
            replay = MESSAGES_TO_REMEMBER
        )

    suspend fun sendMessageToEveryone(message: Message) {
        // Emits through the mutable backing field inside Chatroom
        messages.emit(message)
    }
}

suspend fun main() {
    val nUsers = 3
    val chatroom = Chatroom()

    withContext(Dispatchers.Default) {
        val messageReaders = List(nUsers) { userId ->
            launch(start = CoroutineStart.UNDISPATCHED) {
                chatroom.messages.collect { message ->
                    println("User $userId received $message")
                }
            }
        }

        repeat(nUsers) { userId ->
            chatroom.sendMessageToEveryone(
                Message(
                    senderId = userId,
                    time = Clock.System.now(),
                    text = "Hello from $userId!"
                )
            )
        }

        delay(100.milliseconds)
        messageReaders.forEach { it.cancel() }
    }
}
```

Create a `StateFlow`

`StateFlow` is a hot flow that stores a single state value and emits updates when that value is replaced with a new one. New subscribers receive the current value as soon as they start collecting, and then receive new values each time the state updates.

You can use `StateFlow` to represent state that changes over time, such as loading progress, UI state, or the state of an object.

To create a `StateFlow`, use the `MutableStateFlow()` function with an initial value:

```
// Creates a MutableStateFlow with LoadingState.Started as the initial value
val result = MutableStateFlow<LoadingState>(LoadingState.Started)
```

To set the current state, use the `value` property:

```
fun loadBlob(url: String): StateFlow<LoadingState> {
    val result = MutableStateFlow<LoadingState>(LoadingState.Started)

    DownloadManager.startLoading(
        url,
        onPercentageLoaded = { percentage →
            // Replaces the current state with the latest progress
            result.value = LoadingState.Percentage(percentage)
        },
        onCompletion = {
            // Replaces the current state with the completion state
            result.value = LoadingState.Done
        },
        onFailure = {
            // Replaces the current state with the failure state
            result.value = LoadingState.Failed
        }
    )
}
```

Setting `value` is thread-safe and replaces the current state, but updating `value` based on its previous value isn't atomic. When a new state depends on the previous state, use `.update()` instead.

Similar to `MutableSharedFlow`, `MutableStateFlow` exposes APIs for emitting updates. If you expose it directly, any code that receives it can update the state by downcasting it to `MutableStateFlow`.

To prevent this, expose the mutable flow as a read-only `StateFlow` with the `.asStateFlow()` function:

```
fun loadBlob(url: String): StateFlow<LoadingState> {
    val result = MutableStateFlow<LoadingState>(LoadingState.Started)

    DownloadManager.startLoading(
        url,
        onPercentageLoaded = { percentage →
            result.value = LoadingState.Percentage(percentage)
        },
        onCompletion = {
            result.value = LoadingState.Done
        },
        onFailure = {
            result.value = LoadingState.Failed
        }
    )

    // Exposes the loading state as a read-only StateFlow
    return result.asStateFlow()
}
```

Here's an example that uses `StateFlow` to report loading progress from a callback-based API:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration.Companion.seconds
import kotlin.io.encoding.*
import java.io.IOException
import kotlin.random.Random

sealed interface LoadingState {
    sealed interface Terminal: LoadingState
    object Started: LoadingState
    data class Percentage(val percents: Int): LoadingState
    object Failed: Terminal
    object Done: Terminal
}

fun loadBlob(url: String): StateFlow<LoadingState> {
    // Creates a mutable StateFlow with the initial loading state
    val result = MutableStateFlow<LoadingState>(LoadingState.Started)
    DownloadManager.startLoading(
        url,
        onPercentageLoaded = { percentage ->
            // Replaces the current state with the latest progress
            result.value = LoadingState.Percentage(percentage)
        },
        onCompletion = {
            // Replaces the current state with the completion state
            result.value = LoadingState.Done
        },
        onFailure = {
            // Replaces the current state with the failure state
            result.value = LoadingState.Failed
        }
    )
    // Exposes the loading state as a read-only StateFlow
    return result.asStateFlow()
}

// Defines a callback-based API that downloads data asynchronously
object DownloadManager {
    // Starts loading the url asynchronously
    fun startLoading(
        url: String,
        onPercentageLoaded: (Int) -> Unit,
        onCompletion: () -> Unit,
        onFailure: (Throwable) -> Unit
    ) {
        // Uses GlobalScope for illustrative purposes only,
        // to keep this example self-contained
        GlobalScope.launch {
            val failureChancePerStep = 1 - java.lang.Math.pow(0.99, 10.0)

            repeat(10) { step ->
                if (Random.nextDouble() < failureChancePerStep) {
                    onFailure(IOException("Failed to load!"))
                    return@launch
                }
                onPercentageLoaded((step + 1) * 10)
                delay(10.milliseconds)
            }
            onCompletion()
        }
```

```
    }
}

suspend fun main() {
    loadBlob("https://example.com/").onEach { state ->
        when (state) {
            is LoadingState.Started -> {
                // Waits for progress updates
            }
            is LoadingState.Percentage ->
                println("Loaded ${state.percents}...")
            is LoadingState.Failed ->
                println("Loading failed.")
            is LoadingState.Done ->
                println("Finished loading!")
        }
    }.takeWhile { it !is LoadingState.Terminal }.collect()
}
```

This example uses `GlobalScope` only to keep the callback-based API short. In your own applications, pass a `CoroutineScope` to the function that starts the work, such as `startLoading()` in this example, and launch the coroutine in that scope so callers can cancel the work when they no longer need it.

Since `StateFlow` is a hot flow, collection doesn't complete on its own. In this example, the `.takeWhile()` operator stops collection when loading reaches a terminal state.

A `StateFlow` emits an update only when the new value differs from the current value.

Avoid storing mutable objects in a `StateFlow`. Mutating the object itself doesn't replace the current value, so collectors don't receive an update.

You can also update a `StateFlow` by calculating the new state from the current state. Use the `.update()` function for these updates. The `.update()` function updates the value atomically, which helps when multiple coroutines update the same `MutableStateFlow`.

If you only need to update a shared value and don't need to observe state changes over time, use the Kotlin Atomics APIs, such as `AtomicInt` or `AtomicReference`.

Here's an example where likes are stored in a `StateFlow`, and each new state is calculated from the previous state:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration.Companion.seconds
import kotlin.io.encoding.*
import java.io.IOException
import kotlin.random.Random

class Post(val id: Long) {
    // Stores the current number of likes as a StateFlow
    private val _numberOfLikes = MutableStateFlow<Int>(
        // Sets the initial number of likes
        0
    )

    // Exposes a read-only StateFlow with the current number of likes
    val numberOfLikes: StateFlow<Int>
        get() = _numberOfLikes.asStateFlow()

    // Adds a like
    fun like() {
        // Increments the number of likes atomically for concurrent and multithreaded calls
        _numberOfLikes.update { it + 1 }
    }
}

suspend fun drawUpdatedNumberOfLikes(likes: Int) {
    // Displays the latest number of likes
    println("${Clock.System.now()}: the number of likes is $likes")
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        val post = Post(15)
        val notifyingJob = launch {
            post.numberOfLikes.collect {
                drawUpdatedNumberOfLikes(it)
            }
        }
        // Simulates users who like the post
        coroutineScope {
            repeat(10) {
                launch {
                    delay(Random.nextInt(100).milliseconds)
                    post.like()
                }
            }
        }
        // Cancels collection after all simulated users finish
        notifyingJob.cancelAndJoin()
    }
}
```

In this example, the `.update()` function increments the number of likes atomically. This prevents lost updates when multiple coroutines call the `like()` function at the same time.

Store accumulated state in a `StateFlow`

Sometimes you might want subscribers to receive the result of all previous emissions, not only the latest emitted value.

For example, a chat room can keep its message history as a single state value. When a new user joins the chat room, they receive the current message history first. Then they continue receiving updates when new messages arrive.

You can model this behavior with a `StateFlow`.

To do so, store the full message history as the current value with `StateFlow<List<Message>>`, instead of broadcasting each chat message as a separate event with `SharedFlow<Message>`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration.Companion.seconds
import kotlin.io.encoding.*
import java.io.IOException
import kotlin.random.Random

data class Message(
    val senderId: Int,
    val time: Instant,
    val text: String,
)

class Chatroom {
    // Stores the full message history
    private val _messageHistory = MutableStateFlow<List<Message>>(emptyList())

    // Exposes a read-only StateFlow with the current message history
    val messageHistory: StateFlow<List<Message>>
        get() = _messageHistory.asStateFlow()

    // Sends a message to all subscribers of the messageHistory flow
    suspend fun sendMessageToEveryone(message: Message) {
        // Adds the new message to the current history atomically
        _messageHistory.update {
            it + message
        }
    }
}

suspend fun main() {
    val nUsers = 3
    val chatroom = Chatroom()
    withContext(Dispatchers.Default) {
        // Starts a message reader for each user
        val messageReaders = List(nUsers) { userId ->
            launch(start = CoroutineStart.UNDISPATCHED) {
                chatroom.messageHistory.collect { currentHistory ->
                    println("User $userId sees the history as $currentHistory")
                }
            }
        }
        // Sends a greeting from each user
        repeat(nUsers) { userId ->
            chatroom.sendMessageToEveryone(
                Message(
                    userId,
                    Clock.System.now(),
                    "Hello from $userId!"
                )
            )
        }
        // Delays to make sure users have enough time to receive updates
        delay(100.milliseconds)
        // Cancels readers because StateFlow collection doesn't finish by itself
        messageReaders.forEach { it.cancel() }
    }
}
```

In this example, `messageHistory` stores the full list of previous messages as the current state. When a new message is sent, the `.update()` function creates a new list from the previous history and adds the new message atomically.

> Updating immutable collections by creating a new collection can take more time as the collection grows. You can create persistent collections with the Experimental `kotlinx.collections.immutable` library to make immutable collection updates more efficient.

Since `messageHistory` is a `StateFlow`, subscribers receive the current message history when they start collecting. After that, they receive a new list each time a message is sent, which changes the chat history.

Convert cold flows to hot flows

A cold flow runs its upstream operations separately for each collector. When multiple subscribers need emissions from the same upstream collection, you can convert the cold flow to a hot flow that shares that collection with its subscribers.

The following simplified version of `.shareIn()` demonstrates this idea by collecting a cold flow once, emitting its values into a `MutableSharedFlow`, and exposing it as a read-only `SharedFlow`:

```
import kotlinx.coroutines.flow.*
import kotlinx.coroutines.*

fun <T> Flow<T>.simpleShareIn(scope: CoroutineScope): SharedFlow<T> {
    val sharedFlow = MutableSharedFlow<T>()
    scope.launch {
        this@simpleShareIn.collect {
            sharedFlow.emit(it)
        }
    }
    return sharedFlow.asSharedFlow()
}

suspend fun main() {

}
```

In this example, `simpleShareIn()` starts a new coroutine in the provided scope. To stop collecting from the upstream flow, cancel the scope that runs the collecting coroutine.

If the upstream flow throws an exception, this collecting coroutine fails. Use operators such as `.catch()` or `.retry()` before sharing the flow to handle upstream exceptions before the collecting coroutine fails.

The built-in `.shareIn()` function provides this pattern without requiring you to create a `MutableSharedFlow` yourself. It also adds options for controlling when upstream collection starts and stops, and how many previous emissions new subscribers receive.

To use the built-in `.shareIn()` function, provide the following arguments:

- The coroutine scope where the upstream flow is collected.
- The `SharingStarted` strategy that controls when upstream collection starts and stops. For example, `SharingStarted.Eagerly` starts upstream collection immediately in the provided scope, before any subscriber starts collecting.
- The optional `replay` value that controls how many previous emissions new subscribers receive.

The `.shareIn()` function collects the upstream flow in the provided coroutine scope and broadcasts its emissions to subscribers.

Here's an example where `.shareIn()` converts a cold flow to a hot flow that shares serialized chat messages with multiple subscribers:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration.Companion.seconds
import kotlin.io.encoding.*
import java.io.IOException
import kotlin.random.Random

data class Message(
    val senderId: Int,
    val time: Instant,
    val text: String,
)

class Chatroom {
    // Stores the message flow
    private val _messages = MutableSharedFlow<Message>()

    // Exposes a read-only SharedFlow with emitted messages
    // New subscribers don't receive already emitted messages
    val messages: SharedFlow<Message>
        get() = _messages.asSharedFlow()

    // Sends a message to all subscribers of the messages flow
    suspend fun sendMessageToEveryone(message: Message) {
        _messages.emit(message)
    }
}

suspend fun main() {
    val nUsers = 3
    val chatroom = Chatroom()
    withContext(Dispatchers.Default) {
        // Creates a child scope of the currently running coroutine
        val derivedFlowsScope = CoroutineScope(
            currentCoroutineContext() + Job(currentCoroutineContext()[Job])
        )
        // Shares serialized messages between subscribers
        val serializedMessages: SharedFlow<String> =
            chatroom
                .messages
                .map {
                    // Serializes each message once for the shared flow
                    "senderId: ${it.senderId}, time: ${it.time}, text: " +
                        Base64.Default.encode(it.text.encodeToByteArray())
                }
                .shareIn(
                    // Starts the sharing coroutine in this scope.
                    // The upstream flow, including .map(), runs in that coroutine
                    derivedFlowsScope,

                    // Starts collecting the upstream flow immediately,
                    // before the first subscriber appears
                    SharingStarted.Eagerly,

                    // Doesn't replay previous serialized messages to new subscribers
                    replay = 0,
                )

        // Starts a message reader for each user
        val messageReaders = List(nUsers) { userId ->
            launch(start = CoroutineStart.UNDISPATCHED) {
```

```
                serializedMessages.collect { serializedMessage ->
                    println("User $userId observes the message $serializedMessage")
                }
            }
        }
        // Sends a greeting from each user
        repeat(nUsers) { userId ->
            chatroom.sendMessageToEveryone(
                Message(
                    userId,
                    Clock.System.now(),
                    "Hello from $userId!"
                )
            )
        }
        // Delays to make sure users have enough time to receive updates
        delay(100.milliseconds)
        // Cancels readers because SharedFlow collection doesn't finish by itself
        messageReaders.forEach { it.cancel() }
        // Cancels the scope that runs the derived hot flow
        derivedFlowsScope.cancel()
    }
}
```

In this example, the `.map()` operator creates a cold flow that serializes each message. Without the `.shareIn()` function, each collector runs that serialization separately. The `.shareIn()` function shares one upstream collection, so each message is serialized once and then shared with all subscribers.

Because `SharingStarted.Eagerly` starts upstream collection immediately, the derived hot flow starts collecting `chatroom.messages` as soon as `.shareIn()` is called.

Similarly, to convert a cold flow to a `StateFlow`, use the `.stateIn()` function.

Unlike `.shareIn()`, `.stateIn()` requires an initial value because a `StateFlow` must always have a current value.

For example:

```
val lastUpdateFlow: StateFlow<Instant?> =
    chatroom
        .messageHistory
        .map { currentHistory -> currentHistory.lastOrNull()?.time }
        .stateIn(
            // Starts the sharing coroutine in this scope
            // The upstream flow, including .map(), runs in that coroutine
            derivedFlowsScope,

            // Starts collecting when the first subscriber appears
            // and stops when the last subscriber disappears
            SharingStarted.WhileSubscribed(),
            // Sets the initial state before the first upstream emission
            null,
        )
```

Cancel hot flows

Hot flows don't stop when a subscriber is canceled.

When you cancel the coroutine that collects a hot flow, you only cancel that subscriber. The hot flow can still emit values to other subscribers, and the coroutine that produces those values can keep running.

Hot flows themselves don't have a cancellation operation. To cancel a hot flow, cancel the coroutine or scope that produces values for it.

Hot flows created with the `.shareIn()` or `.stateIn()` extension functions continue to collect the upstream flow until the sharing coroutine is canceled. To stop collection from the upstream flow, cancel the scope that runs the sharing coroutine.

> You can also stop upstream collection automatically when there are no subscribers with `SharingStarted.WhileSubscribed()`.

Here's an example where canceling the scope passed to `.stateIn()` stops a derived hot flow from collecting new values:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.Duration.Companion.seconds
import kotlin.io.encoding.*
import java.io.IOException
import kotlin.random.Random

data class Message(
    val senderId: Int,
    val time: Instant,
    val text: String,
)

class Chatroom {
    // Stores the message history
    private val _messageHistory = MutableStateFlow<List<Message>>(emptyList())

    // Exposes a read-only StateFlow with the current message history
    val messageHistory: StateFlow<List<Message>>
        get() = _messageHistory.asStateFlow()

    // Sends a message to all subscribers of the messageHistory flow
    suspend fun sendMessageToEveryone(message: Message) {
        _messageHistory.update {
            it + message
        }
    }
}

suspend fun main() {
    val chatroom = Chatroom()
    withContext(Dispatchers.Default) {
        // Creates a child scope of the currently running coroutine
        val derivedFlowsScope = CoroutineScope(
            currentCoroutineContext() + Job(currentCoroutineContext()[Job])
        )
        val totalMessages = chatroom.messageHistory
            .map { currentHistory ->
                currentHistory.size
            }.onEach {
                println("There are currently $it messages")
            }.stateIn(
                // Starts the sharing coroutine in this scope
                derivedFlowsScope
            )
        // Updates messageHistory
        chatroom.sendMessageToEveryone(
            Message(0, Clock.System.now(), "We are shutting down soon!")
        )
        delay(100.milliseconds)
        // Cancels the scope that runs the derived hot flow
        derivedFlowsScope.cancel()
        // Updates messageHistory, but totalMessages no longer receives the update
        chatroom.sendMessageToEveryone(
            Message(0, Clock.System.now(), "We have shut down.")
        )
        println("Last collected history size: ${totalMessages.value}")
        println("Actual history size: ${chatroom.messageHistory.value.size}")
    }
}
```

In this example, when you call the `derivedFlowsScope.cancel()` function, `totalMessages` stops collecting updates from `messageHistory`.

The `sendMessageToEveryone()` function still updates `messageHistory` because the coroutine that calls it wasn't canceled. As a result, `totalMessages.value` keeps the last collected size, while `chatroom.messageHistory.value.size` shows the actual number of messages.

Handle exceptions in hot flows

In cold flows, upstream exceptions propagate to the caller of `collect()` unless you use an operator such as `.catch()` to handle them first.

Hot flows don't propagate exceptions from producers to subscribers. If code that emits to a `MutableSharedFlow` or updates a `MutableStateFlow` throws an exception, handle it in the coroutine that runs that code. If a subscriber throws an exception while collecting, handle it in the collecting coroutine.

Hot flows created with the `.shareIn()` or `.stateIn()` extension functions collect from the upstream flow in a sharing coroutine. If the upstream flow throws an exception, the exception cancels the sharing coroutine:

```
import kotlinx.coroutines.flow.*
import kotlinx.coroutines.*

suspend fun main() {
    withContext(Dispatchers.Default) {
        launch {
            flow<Int> {
                error("An upstream failure")
            }.stateIn(
                this@launch
            )
        }
    }
}
```

You can restart upstream collection after a failure. To do so, place the `.retry()` operator before `.shareIn()` or `.stateIn()`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() {
    coroutineScope {
        launch {
            var currentAttempt = 0

            val stateFlow = flow {
                delay(10.milliseconds)

                if (currentAttempt++ < 5) {
                    println("An error happened!")
                    error("An upstream failure")
                } else {
                    println("Success.")
                    emit(10)
                }
            }
                // Restarts the upstream flow after recoverable failures
                .retry(retries = 5)
                .stateIn(
                    // Starts the sharing coroutine in this scope
                    this@launch
                )

            stateFlow.collect {
                println("Observed $it")

                // Cancels collection and the sharing coroutine
                this@launch.cancel()
            }
        }
    }
}
```

In this example, the flow fails five times before it emits a value. Because `.retry()` runs before `.stateIn()`, it handles each upstream failure before the failure reaches the sharing coroutine.

After the upstream flow emits `10`, the collecting coroutine receives the value and cancels itself. Since the same coroutine is also the parent of the sharing coroutine, this stops the derived hot flow.

Flow operators

Flow operators let you transform and process values in a flow pipeline. Kotlin provides two main kinds of flow operators:

- **Intermediate operators** return a new downstream flow that consumes values from upstream flows and applies an operation to them.
- **Terminal operators** trigger the execution of the flow pipeline by collecting an upstream flow. They may also return a result.

While the `kotlinx.coroutines` library offers a wide range of flow operators, you can also define custom ones when you need behavior that the built-in operators don't provide.

The following sections include examples for custom implementations alongside the corresponding built-in operators.

Intermediate operators

Intermediate operators return a new downstream flow that consumes values from upstream flows. You can chain several intermediate operators to build a flow pipeline before collecting the final result.

Intermediate operators can be classified by purpose into the following categories:

- **Transforming operators** transform values before emitting them downstream.
- **Filtering and size-limiting operators** control which upstream values continue downstream.
- **Concurrent processing operators** let emissions run separately from collection.
- **Combining operators** collect values from multiple upstream flows and emit them into one downstream flow.
- **Lifecycle operators** run actions in response to specific events during flow collection, such as when collection starts or when the upstream flow completes.

Transforming operators

Transforming operators transform the values emitted by an upstream flow. You can use them to convert values to another type, skip values, or emit additional values downstream.

Transforming operators accept suspending lambdas, so their lambdas can call suspending functions while processing each emitted value. They still process values sequentially unless the flow pipeline uses an operator that introduces concurrency.

The `.transform()` operator is a general transforming operator that you can use as the basis for more specific transforming operators, such as `.map()` and `.filter()`.

Here's an example that uses the `.transform()` operator to emit each upstream value as many times as its value:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom implementation of the default .transform() operator
inline fun <T, R> Flow<T>.myTransform(
    // Accepts a suspending lambda that can emit values downstream
    crossinline transform: suspend FlowCollector<R>.(value: T) -> Unit
): Flow<R> = flow {
    // Collects values from the upstream flow
    this@myTransform.collect { value ->
        // Applies the transformation and emits values to the downstream flow
        this@flow.transform(value)
    }
}

// Uses the default .transform() operator
suspend fun main() = withContext(Dispatchers.Default) {
    val flow = (0..4).asFlow().transform { value ->
        // Emits each value as many times as its value
        repeat(value) {
            emit(value)
        }
    }
    println(flow.toList())
    // [1, 2, 2, 3, 3, 3, 4, 4, 4, 4]
}
```

You can use the `.map()` operator to transform each upstream value into one downstream value.

Here's an example that uses `.map()` to multiply each value by four:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom implementation of the default .map() operator
inline fun <T, R> Flow<T>.myMap(
    crossinline transform: suspend (value: T) -> R
): Flow<R> = transform { value ->
    emit(transform(value))
}

suspend fun main() = withContext(Dispatchers.Default) {
    // Multiplies each upstream value by four
    val flow = (0..4).asFlow().map { it * 4 }
    println(flow.toList())
    // [0, 4, 8, 12, 16]
}
```

To emit only upstream values that match a condition, use the `.filter()` operator.

Here's an example that emits values where dividing by `3` leaves a remainder of `1`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom implementation of the default .filter() operator
inline fun <T> Flow<T>.myFilter(
    crossinline predicate: suspend (value: T) -> Boolean
): Flow<T> = transform { value ->
    // Emits only values that match the condition
    if (predicate(value))
        emit(value)
}

suspend fun main() = withContext(Dispatchers.Default) {
    // Emits only values where dividing by 3 leaves a remainder of 1
    val flow = (0..10).asFlow().filter { it % 3 == 1 }
    println(flow.toList())
    // [1, 4, 7, 10]
}
```

Some operators can combine the behavior of other transforming operators, such as `.map()` and `.filter()`, by transforming values and emitting only the results that match a condition.

For example, use `.mapNotNull()` to transform each upstream value and emit only non-null results:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom implementation of the default .mapNotNull() operator
inline fun <T, R: Any> Flow<T>.myMapNotNull(
    crossinline transform: suspend (value: T) -> R?
): Flow<R> = transform { value ->
    transform(value)?.let { transformed ->
        emit(transformed)
    }
}

suspend fun main() = withContext(Dispatchers.Default) {
    // Converts each string to Double and skips values that can't be converted
    val flow = flowOf("1.2", "10", "11", "error", "0.000")
        .mapNotNull { it.toDoubleOrNull() }

    println(flow.toList())
    // [1.2, 10.0, 11.0, 0.0]
}
```

Filtering and size-limiting operators

Filtering and size-limiting operators control which values continue downstream from a flow. You can use them to remove repeated consecutive values, skip values from the beginning of a flow, or cancel collection after a specified number of values.

To ignore repeated consecutive values, use the `.distinctUntilChanged()` operator. It emits a value only when it differs from the previously emitted value:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom version of the default .distinctUntilChanged() operator
fun <T> Flow<T>.myDistinctUntilChanged(): Flow<T> = flow {
    var lastEmitted: Any? = Any() // A value that's equal only to itself
    this@myDistinctUntilChanged.collect { value ->
        if (lastEmitted != value) {
            this@flow.emit(value)
            lastEmitted = value
        }
    }
}

suspend fun main() = withContext(Dispatchers.Default) {
    // Removes repeated consecutive values from the upstream flow
    val flow = flowOf(1, 2, 3, 3, 3, 4, 5, 5, 1).distinctUntilChanged()
    println(flow.toList())
    // [1, 2, 3, 4, 5, 1]
}
```

You can use the `.drop()` operator to skip the first values emitted by an upstream flow. For example, `.drop(2)` skips the first two values and emits the remaining values downstream:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom version of the default .drop() operator
fun <T> Flow<T>.myDrop(count: Int): Flow<T> = flow {
    require(count >= 0)
    var elementsAlreadyDropped = 0
    this@myDrop.collect { value ->
        if (elementsAlreadyDropped == count) {
            this@flow.emit(value)
        } else {
            ++elementsAlreadyDropped
        }
    }
}

suspend fun main() = withContext(Dispatchers.Default) {
    // Skips the first two values from the upstream flow
    val flow = flowOf(1, 2, 3, 4, 5).drop(2)
    println(flow.toList())
    // [3, 4, 5]
}
```

To cancel collection after a fixed number of values, use the `.take()` operator. Here's an example that uses the `.take()` operator to collect only the first three values:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.*
import java.io.IOException
import kotlin.time.Duration.Companion.milliseconds

// A simplified custom version of the default .take() operator
fun <T> Flow<T>.myTake(count: Int): Flow<T> = flow {
    require(count > 0)
    val cancellationException = CancellationException()
    var elementsRemaining = count
    try {
        this@myTake.collect {
            emit(it)
            --elementsRemaining
            if (elementsRemaining == 0) {
                // Cancels the upstream flow after the requested number of values
                throw cancellationException
            }
        }
    } catch (e: Throwable) {
        if (e === cancellationException) {
            // Handles the CancellationException used to cancel the upstream flow
            // Completes the flow after the set number of values in .myTake()
        } else {
            // Rethrows unexpected exceptions
            throw e
        }
    }
}

suspend fun main() = withContext(Dispatchers.Default) {
    // Collects only the first three values from the upstream flow
    val flow = (0..1000).asFlow().take(3)

    println(flow.toList())
    // [0, 1, 2]
}
```

Concurrent processing operators

By default, a flow pipeline processes values sequentially. The upstream flow emits a value, and collectors process it before the next value is emitted.

To run the upstream flow concurrently with downstream collection, use concurrent processing operators to introduce a buffer. A buffer stores values that the upstream flow has emitted, but the collector hasn't processed yet.

One operator that introduces this buffer is the `.buffer()` operator. It lets you configure the buffer capacity and what happens when the buffer is full, for example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() = withContext(Dispatchers.Default) {
    flow {
        repeat(10) {
            emit(it)
            println("Emitted $it!")
        }
    }
        // Lets the upstream flow emit up to four values ahead of the collector
        .buffer(4)
        .collect {
            println("Processed $it!")
            delay(20.milliseconds)
        }
}
```

When the collector is slower than the upstream flow, the pipeline needs a way to handle values that the collector hasn't processed yet.

By default, the collector applies *backpressure* to the upstream flow. With this strategy, the upstream flow suspends when the buffer is full and resumes when the collector frees up space.

To drop values instead of suspending the upstream flow, set the `onBufferOverflow` parameter:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.BufferOverflow
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() = withContext(Dispatchers.Default) {
    flow {
        repeat(10) {
            emit(it)
            println("Emitted $it!")
        }
    }
        // Stores up to four values before applying the overflow behavior
        // Drops the oldest buffered value when the buffer is full
        .buffer(4, onBufferOverflow = BufferOverflow.DROP_OLDEST)
        .collect { value ->
            println("Processed $value!")
            delay(20.milliseconds)
        }
}
```

You can also use the `.conflate()` operator, which is a shorthand for `buffer(1, onBufferOverflow = BufferOverflow.DROP_OLDEST)`. Use it when you only want to process the latest values, skipping the values emitted while the previous value is being collected:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() = withContext(Dispatchers.Default) {
    flow {
        repeat(10) {
            emit(it)
            println("Emitted $it!")
        }
    }.conflate().collect {
        println("Processed $it!")
        delay(20.milliseconds)
    }
}
```

The `.conflate()` operator only affects which buffered values the collector processes. It doesn't cancel processing that has already started. To do that, use `collectLatest()` instead.

In the previous examples, the `.buffer()` and `.conflate()` operators run the upstream flow concurrently in a separate coroutine without changing its coroutine context.

To run the upstream flow in a different coroutine context, use the `.flowOn()` operator. If this changes the dispatcher, `.flowOn()` collects the upstream flow in a separate coroutine and uses a buffer between upstream emission and downstream collection.

Here's a simplified example that uses `.flowOn()` to run the upstream flow in `Dispatchers.IO`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds

suspend fun main() = withContext(Dispatchers.Default) {
    flow {
        repeat(10) {
            emit(it)
        }
        println("Finished emitting!")
    }.flowOn(Dispatchers.IO).collect {
        println("Received $it!")
        delay(10.milliseconds)
    }
}
```

In this example, the `.flowOn()` operator can introduce concurrent upstream processing, but the buffer behavior isn't configured explicitly.

To configure both the coroutine context of the upstream flow and the buffer behavior, combine `.flowOn()` with `.buffer()` or `.conflate()`. When you use these operators together, the operators perform *operator fusion* and share a single buffer.

Here's an example that uses `.flowOn(Dispatchers.IO)` to run the upstream flow in `Dispatchers.IO` and `.conflate()` to keep the newest buffered value:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.Random
import kotlin.time.Duration.Companion.milliseconds
import kotlin.math.round

fun awaitSensorSignal(): SensorSignal {
    Thread.sleep(10)
    val reading =
        round(Random.nextDouble(25.0, 100.0) * 100.0)/100.0
    println("Measured $reading as the temperature")
    return SensorSignal(temperatureCelsius = reading)
}

data class SensorSignal(
    val temperatureCelsius: Double
)

suspend fun sendLatestTemperature(temperatureCelsius: Double) {
    println("Starting to send $temperatureCelsius...")
    delay(50.milliseconds)
    println("Sent $temperatureCelsius.")
}

suspend fun main() = withContext(Dispatchers.Default) {
    val smartHomeTemperatureFlow = flow {
        while (true) {
            val signal = awaitSensorSignal()
            emit(signal.temperatureCelsius)
            println("Emitted $signal")
        }
    }
        // Runs the upstream flow in Dispatchers.IO
        .flowOn(Dispatchers.IO)
        // Keeps the newest buffered value and drops older ones
        .conflate()
        // Collects the first two values from the upstream flow
        .take(2)
        .collect { temperature ->
            println("Received $temperature!")
            sendLatestTemperature(temperature)
        }
}
```

Combining operators

Combining operators consume values from multiple upstream flows and return a single downstream flow. Use them when collectors need values from more than one flow.

To pair values from two upstream flows, use the `.zip()` operator. It combines the first value from each flow, then the second value from each flow, and so on. The resulting flow completes as soon as one of the upstream flows completes.

Here's an example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.random.Random
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

suspend fun main() = withContext(Dispatchers.Default) {
    // Emits a ticker value every 100 milliseconds
    val tickerFlow = flow {
        while (true) {
            emit(Unit)
            delay(100.milliseconds)
        }
    }

    val start = TimeSource.Monotonic.markNow()
    tickerFlow
        // Combines each ticker emission with the next number
        .zip(flowOf(1, 2, 3)) { _, value ->
            value
        }.collect {
            println("${start.elapsedNow()}: received $it")
        }
}
```

To combine the latest value from multiple flows, use the `.combine()` operator. It emits a new value when any upstream flow emits a value, using the latest value from each upstream flow:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

enum class Theme {
    Dark,
    Light,
}

data class UiState(
    val messages: List<String>,
    val theme: Theme,
)

val messagesFlow = MutableStateFlow(
    listOf(
        "Hello!",
        "Is anyone here?",
    )
)

val themeFlow = MutableStateFlow(
    Theme.Light
)

// Combines the latest values from both upstream flows
val uiStateFlow = combine(messagesFlow, themeFlow) { messages, theme ->
    UiState(messages, theme)
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        // Uses UNDISPATCHED to subscribe before the first update happens
        val uiUpdateJob = launch(start = CoroutineStart.UNDISPATCHED) {
            uiStateFlow.collect {
                // Draws the UI
                println(it)
            }
        }
        messagesFlow.update { messages -> messages + "I'll be back!" }
        delay(100.milliseconds)

        themeFlow.value = Theme.Dark
        delay(100.milliseconds)

        uiUpdateJob.cancel()
    }
}
```

In this example, `combine()` creates `uiStateFlow` from the latest values of `messagesFlow` and `themeFlow`. Updating either upstream flow emits a new `UiState` with the latest messages and theme.

If you want to collect values from multiple flows concurrently and emit their values into one downstream flow, use the `.merge()` operator:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

interface UiEvent

class ClickEvent: UiEvent

class RightClickEvent: UiEvent

suspend fun main() {
    withContext(Dispatchers.Default) {

        val clickFlow = MutableSharedFlow<ClickEvent>()
        val rightClickFlow = MutableSharedFlow<RightClickEvent>()

        coroutineScope {
            // Uses UNDISPATCHED to subscribe before the first update happens
            val collectJob = launch(start = CoroutineStart.UNDISPATCHED) {

                // Collects both upstream flows concurrently and emits their values downstream
                merge(clickFlow, rightClickFlow).collect {
                    println("Observed an event: $it")
                }
            }
            clickFlow.emit(ClickEvent())
            delay(100.milliseconds)

            clickFlow.emit(ClickEvent())
            delay(100.milliseconds)

            rightClickFlow.emit(RightClickEvent())
            delay(100.milliseconds)

            collectJob.cancel()
        }
    }
}
```

Lifecycle operators

Lifecycle operators accept a suspending lambda that runs at a specific point during flow collection. You can use them to place logic before the flow is collected, before each value is emitted, after collection completes, or when the flow completes without emitting values.

The `.onStart()` operator runs its lambda before the upstream flow is collected. For code that needs to run before each emitted value, use `.onEach()`.

> Similarly to `.onStart()`, you can use `.onSubscription()` for hot flows to run code after a subscriber starts collecting the flow, but before it collects any emitted values.

Here's an example that uses these operators to print a message before collection starts and before each value is emitted downstream:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

// A simplified custom version of the default .onStart() operator
fun <T> Flow<T>.myOnStart(
    action: suspend FlowCollector<T>.() -> Unit
): Flow<T> = flow {
    this@flow.action()
    this@myOnStart.collect(this@flow)
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        flowOf("Page 1", "Page 2", "Page 3").onStart {
            println("Processing pages!")
        }.onEach {
            println("Emitted $it")
        }.collect {
            println("Collected $it")
        }
    }
}
```

To run code after collection completes, use the `.onCompletion()` operator. Its lambda can emit values downstream when the upstream flow completes successfully, for example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

// A simplified custom version of the default .onCompletion() operator
fun <T> Flow<T>.myOnCompletion(
    action: suspend FlowCollector<T>.(cause: Throwable?) -> Unit
): Flow<T> = flow {
    var exception: Throwable? = null
    try {
        this@myOnCompletion.collect(this@flow)
    } catch (e: Throwable) {
        // Run `action`, but if `action` calls `emit`, throw `e` from it
        FlowCollector<T> { throw e }.action(e)
        throw e
    }
    this@flow.action(null)
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        flowOf("Page 1", "Page 2", "Page 3").onCompletion {
            println("Almost done...")
            // Emits an additional value after the upstream flow completes
            emit("Last Page!")
        }.collect {
            println("Collected $it")
        }
    }
}
```

To run code when the upstream flow completes without emitting any values, use the `.onEmpty()` operator:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

// A simplified custom version of the default .onEmpty() operator
fun <T> Flow<T>.myOnEmpty(
    action: suspend FlowCollector<T>.() -> Unit
): Flow<T> = flow {
    var emittedSomething = false
    this@myOnEmpty.collect { value ->
        emittedSomething = true
        this@flow.emit(value)
    }
    if (!emittedSomething) {
        action()
    }
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        flowOf("Page 1", "Page 2", "Page 3").onEmpty {
            // Doesn't print anything, because the upstream flow emits values
            println("No pages to load!")
        }.collect()
        flowOf<Int>().onEmpty {
            println("No pages to load!")
            // No pages to load!
        }.collect()
    }
}
```

Terminal operators

Terminal operators collect a flow. You can use them to consume emitted values, return a result based on the collected values, or collect a flow in a specific `CoroutineScope`.

To collect a flow, use the `collect()` operator. If you pass a lambda to `collect()`, it receives each emitted value:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    withContext(Dispatchers.Default) {
        flowOf(1, 2, 3).collect {
            println("Collected $it!")
        }
    }
}
```

You can also call `collect()` without a lambda:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    withContext(Dispatchers.Default) {
        flowOf(1, 2, 3).onEach {
            println("Collected $it!")
        }.collect()
    }
}
```

If you want to collect a flow but cancel unfinished work when a new value is emitted, use the `collectLatest()` operator:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

suspend fun main() {
    withContext(Dispatchers.Default) {
        flow {
            println("Emitting Page 1")
            emit("Page 1")
            delay(50.milliseconds)
            println("Emitting Page 2 in quick succession")
            emit("Page 2")
            delay(200.milliseconds)
            println("Emitting Page 3")
            emit("Page 3")
        }.flowOn(Dispatchers.IO).collectLatest {
            println("Starting to process $it!")
            try {
                delay(100.milliseconds)
            } catch (e: CancellationException) {
                println("Canceled processing $it.")
                throw e
            }
            println("Done processing!")
        }
    }
}
```

Some terminal operators collect a flow and return a result based on the collected values. For example, you can use the `.first()` operator to return the first emitted value and then cancel collection:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

suspend fun main() {
    withContext(Dispatchers.Default) {
        val firstValue = flowOf(1, 2, 3).first()

        println(firstValue)
        // 1
    }
}
```

You can collect emitted values into a collection with the `.toList()` or `.toSet()` operators:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

// A simplified custom implementation of the default .toList() operator
suspend fun <T> Flow<T>.myToList(): List<T> = buildList {
    this@myToList.collect { value ->
        // Adds each emitted value to the resulting list
        add(value)
    }
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        val list = flowOf(1, 2, 3).toList()
        println(list)
        // [1, 2, 3]

        val set = flowOf(1, 2, 2, 3).toSet()
        println(set)
        // [1, 2, 3]
    }
}
```

To combine emitted values into a single result, use the `.reduce()` or `.fold()` operators. The `.fold()` operator uses the value you provide as its starting value, and the `.reduce()` operator uses the first emitted value instead.

Here's an example:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*

suspend fun main() {
    withContext(Dispatchers.Default) {
        // Uses the first emitted value as the starting value
        val reduced = flowOf(1, 2, 3).reduce { accumulator, value ->
            accumulator + value
        }

        // Starts with the provided starting value
        val folded = flowOf(1, 2, 3).fold(2) { accumulator, value ->
            accumulator + value
        }

        println(reduced)
        // 6

        println(folded)
        // 8
    }
}
```

Collect a flow in a specific `CoroutineScope`

When a screen or another long-lived object needs values from a flow, start the collector in that object's `CoroutineScope`. This ensures that canceling the object's `CoroutineScope` when the object is destroyed also cancels collection.

To collect a flow in a specific `CoroutineScope`, use the `.launchIn()` terminal operator. This operator returns the `Job` of the collecting coroutine.

Here's an example where a screen collects values from a `StateFlow` and stops the collecting coroutine when the screen closes:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.time.Duration.Companion.milliseconds
import kotlin.time.TimeSource

// A simplified custom version of the default .launchIn() operator
fun <T> Flow<T>.myLaunchIn(scope: CoroutineScope): Job = scope.launch {
    this@myLaunchIn.collect()
}

data class Coordinate(val x: Int, val y: Int)

class MyScreen(val scope: CoroutineScope) {
    private val _mousePosition =
        MutableStateFlow<Coordinate>(Coordinate(0, 0))
    val mousePosition get() = _mousePosition.asStateFlow()

    init {
        // Starts collecting the StateFlow in the screen's CoroutineScope
        mousePosition.onEach {
            updateStatusBar()
        }.launchIn(scope)
    }

    fun moveMouse(newCoordinate: Coordinate) {
        _mousePosition.value = newCoordinate
    }

    private fun updateStatusBar() {
        println("Mouse is at ${_mousePosition.value}")
    }
}

suspend fun main() {
    withContext(Dispatchers.Default) {
        val childScope = CoroutineScope(
            currentCoroutineContext() + Job(currentCoroutineContext()[Job])
        )
        val screen = MyScreen(childScope)
        delay(100.milliseconds)

        screen.moveMouse(Coordinate(10, 15))
        delay(100.milliseconds)

        screen.moveMouse(Coordinate(1, 3))
        delay(100.milliseconds)

        childScope.cancel()
    }
}
```

Coroutines and channels - tutorial

An upcoming update will revise this tutorial. In the meantime, for an up-to-date guide to getting started with coroutines, see Coroutines basics.

In this tutorial, you'll learn how to use coroutines in IntelliJ IDEA to perform network requests without blocking the underlying thread or callbacks.

No prior knowledge of coroutines is required, but you're expected to be familiar with basic Kotlin syntax.

You'll learn:

- Why and how to use suspending functions to perform network requests.
- How to send requests concurrently using coroutines.
- How to share information between different coroutines using channels.

For network requests, you'll need the Retrofit library, but the approach shown in this tutorial works similarly for any other libraries that support coroutines.

You can find solutions for all of the tasks on the `solutions` branch of the project's repository.

Before you start

1. Download and install the latest version of IntelliJ IDEA.
2. Clone the project template by choosing **Get from VCS** on the Welcome screen or selecting **File | New | Project from Version Control**.

   You can also clone it from the command line:

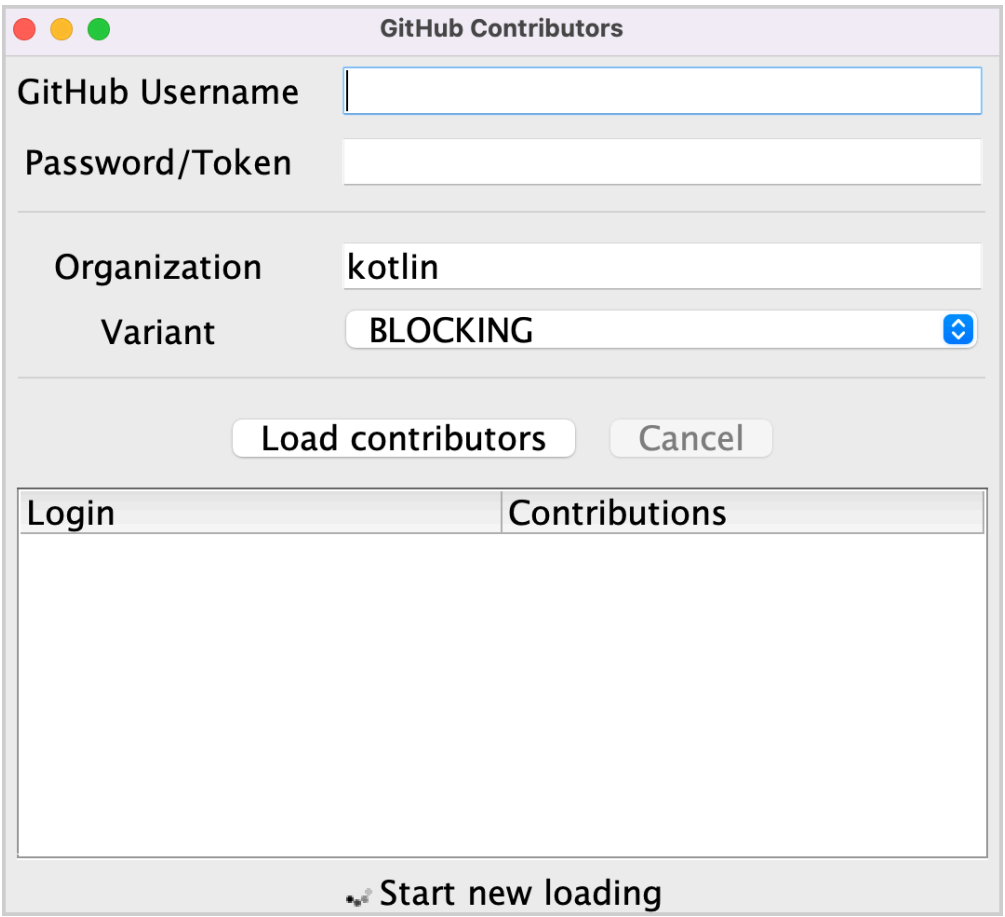
   ```
   git clone https://github.com/kotlin-hands-on/intro-coroutines
   ```

Generate a GitHub developer token

You'll be using the GitHub API in your project. To get access, provide your GitHub account name and either a password or a token. If you have two-factor authentication enabled, a token will be enough.

Generate a new GitHub token to use the GitHub API with your account:

1. Specify the name of your token, for example, `coroutines-tutorial` :



Generate a new GitHub token

2. Do not select any scopes. Click **Generate token** at the bottom of the page.
3. Copy the generated token.

Run the code

The program loads the contributors for all of the repositories under the given organization (named "kotlin" by default). Later you'll add logic to sort the users by the number of their contributions.

1. Open the `src/contributors/main.kt` file and run the `main()` function. You'll see the following window:

First window

If the font is too small, adjust it by changing the value of `setDefaultFontSize(18f)` in the `main()` function.

2. Provide your GitHub username and token (or password) in the corresponding fields.
3. Make sure that the *BLOCKING* option is selected in the *Variant* dropdown menu.
4. Click *Load contributors*. The UI should freeze for some time and then show the list of contributors.
5. Open the program output to ensure the data has been loaded. The list of contributors is logged after each successful request.

There are different ways of implementing this logic: by using blocking requests or callbacks. You'll compare these solutions with one that uses coroutines and see how channels can be used to share information between different coroutines.

Blocking requests

You will use the Retrofit library to perform HTTP requests to GitHub. It allows requesting the list of repositories under the given organization and the list of contributors for each repository:

```
interface GitHubService {
    @GET("orgs/{org}/repos?per_page=100")
    fun getOrgReposCall(
        @Path("org") org: String
    ): Call<List<Repo>>

    @GET("repos/{owner}/{repo}/contributors?per_page=100")
    fun getRepoContributorsCall(
        @Path("owner") owner: String,
        @Path("repo") repo: String
    ): Call<List<User>>
}
```

This API is used by the `loadContributorsBlocking()` function to fetch the list of contributors for the given organization.

1. Open `src/tasks/Request1Blocking.kt` to see its implementation:

```
fun loadContributorsBlocking(
    service: GitHubService,
    req: RequestData
): List<User> {
    val repos = service
        .getOrgReposCall(req.org)   // #1
        .execute()                  // #2
        .also { logRepos(req, it) } // #3
        .body() ?: emptyList()      // #4

    return repos.flatMap { repo ->
        service
            .getRepoContributorsCall(req.org, repo.name) // #1
            .execute()                                   // #2
            .also { logUsers(repo, it) }                 // #3
            .bodyList()                                  // #4
    }.aggregate()
}
```

-

At first, you get a list of the repositories under the given organization and store it in the `repos` list. Then for each repository, the list of contributors is requested, and all of the lists are merged into one final list of contributors.

- `getOrgReposCall()` and `getRepoContributorsCall()` both return an instance of the `*Call` class (`#1`). At this point, no request is sent.
- `*Call.execute()` is then invoked to perform the request (`#2`). `execute()` is a synchronous call that blocks the underlying thread.
- When you get the response, the result is logged by calling the specific `logRepos()` and `logUsers()` functions (`#3`). If the HTTP response contains an error, this error will be logged here.
- Finally, get the response's body, which contains the data you need. For this tutorial, you'll use an empty list as a result in case there is an error, and you'll log the corresponding error (`#4`).

2. To avoid repeating `.body() ?: emptyList()` , an extension function `bodyList()` is declared:

```
fun <T> Response<List<T>>.bodyList(): List<T> {
    return body() ?: emptyList()
}
```

3. Run the program again and take a look at the system output in IntelliJ IDEA. It should have something like this:

```
1770 [AWT-EventQueue-0] INFO  Contributors - kotlin: loaded 40 repos
2025 [AWT-EventQueue-0] INFO  Contributors - kotlin-examples: loaded 23 contributors
2229 [AWT-EventQueue-0] INFO  Contributors - kotlin-koans: loaded 45 contributors
...
```

- The first item on each line is the number of milliseconds that have passed since the program started, then the thread name in square brackets. You can see from which thread the loading request is called.
- The final item on each line is the actual message: how many repositories or contributors were loaded.

This log output demonstrates that all of the results were logged from the main thread. When you run the code with a *BLOCKING* option, the window freezes and doesn't react to input until the loading is finished. All of the requests are executed from the same thread as the one called `loadContributorsBlocking()` is from, which is the main UI thread (in Swing, it's an AWT event dispatching thread). This main thread becomes blocked, and that's why the UI is frozen:

The blocked main thread

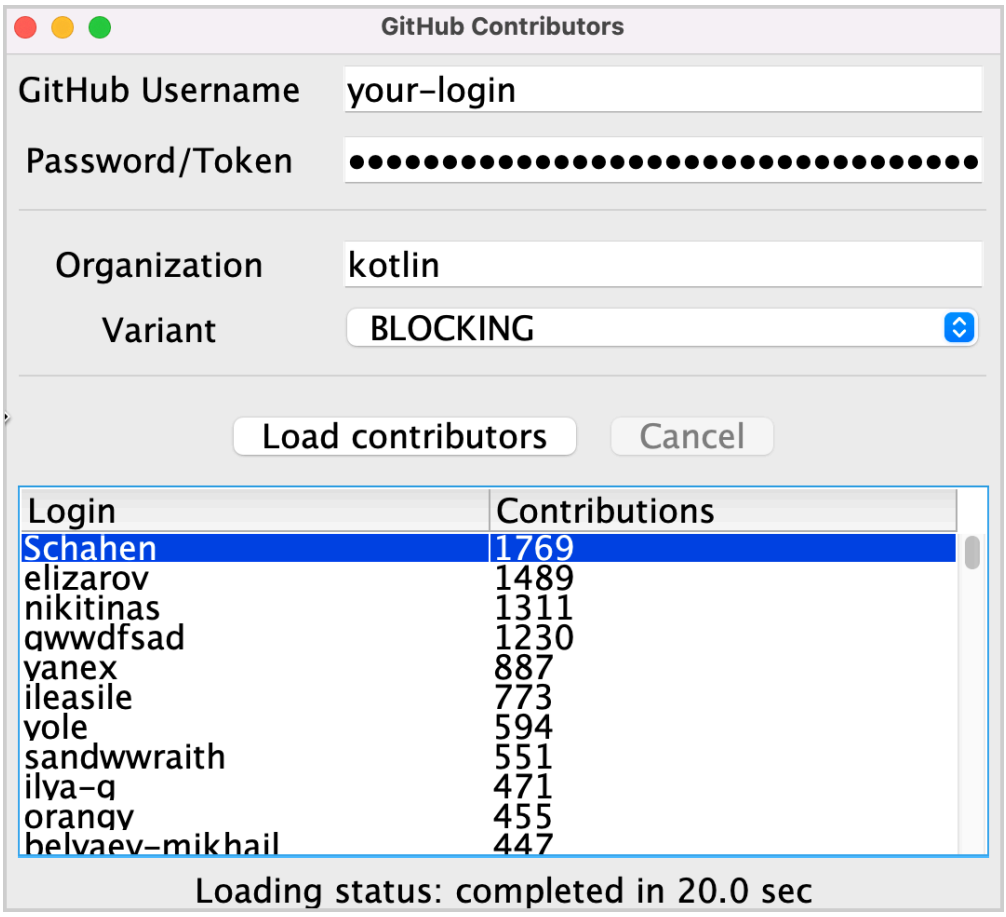
After the list of contributors has loaded, the result is updated.

4. In `src/contributors/Contributors.kt` , find the `loadContributors()` function responsible for choosing how the contributors are loaded and look at how `loadContributorsBlocking()` is called:

```
when (getSelectedVariant()) {
    BLOCKING -> { // Blocking UI thread
        val users = loadContributorsBlocking(service, req)
        updateResults(users, startTime)
    }
}
```

- The `updateResults()` call goes right after the `loadContributorsBlocking()` call.
- `updateResults()` updates the UI, so it must always be called from the UI thread.
- Since `loadContributorsBlocking()` is also called from the UI thread, the UI thread becomes blocked and the UI is frozen.

Task 1



The first task helps you familiarize yourself with the task domain. Currently, each contributor's name is repeated several times, once for every project they have taken part in. Implement the `aggregate()` function combining the users so that each contributor is added only once. The `User.contributions` property should contain the total number of contributions of the given user to *all* the projects. The resulting list should be sorted in descending order according to the number of contributions.

Open `src/tasks/Aggregation.kt` and implement the `List<User>.aggregate()` function. Users should be sorted by the total number of their contributions.

The corresponding test file `test/tasks/AggregationKtTest.kt` shows an example of the expected result.

> You can jump between the source code and the test class automatically by using the IntelliJ IDEA shortcut `Ctrl+Shift+T` / `⇧ ⌘ T`.

After implementing this task, the resulting list for the "kotlin" organization should be similar to the following:

The list for the "kotlin" organization

Solution for task 1

1. To group users by login, use `groupBy()`, which returns a map from a login to all occurrences of the user with this login in different repositories.
2. For each map entry, count the total number of contributions for each user and create a new instance of the `User` class by the given name and total of contributions.
3. Sort the resulting list in descending order:

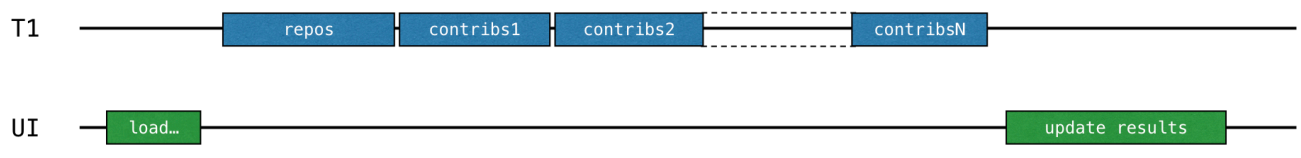
```
fun List<User>.aggregate(): List<User> =
    groupBy { it.login }
        .map { (login, group) -> User(login, group.sumOf { it.contributions }) }
        .sortedByDescending { it.contributions }
```

An alternative solution is to use the `groupingBy()` function instead of `groupBy()`.

Callbacks

The previous solution works, but it blocks the thread and therefore freezes the UI. A traditional approach that avoids this is to use *callbacks*.

Instead of calling the code that should be invoked right after the operation is completed, you can extract it into a separate callback, often a lambda, and pass that lambda to the caller in order for it to be called later.



To make the UI responsive, you can either move the whole computation to a separate thread or switch to the Retrofit API which uses callbacks instead of blocking calls.

Use a background thread

1. Open `src/tasks/Request2Background.kt` and see its implementation. First, the whole computation is moved to a different thread. The `thread()` function starts a new thread:

```
thread {
    loadContributorsBlocking(service, req)
}
```

Now that all of the loading has been moved to a separate thread, the main thread is free and can be occupied by other tasks:

The freed main thread

2. The signature of the `loadContributorsBackground()` function changes. It takes an `updateResults()` callback as the last argument to call it after all the loading completes:

```
fun loadContributorsBackground(
    service: GitHubService, req: RequestData,
    updateResults: (List<User>) -> Unit
)
```

3. Now when the `loadContributorsBackground()` is called, the `updateResults()` call goes in the callback, not immediately afterward as it did before:

```
loadContributorsBackground(service, req) { users →
    SwingUtilities.invokeLater {
        updateResults(users, startTime)
    }
}
```

   By calling `SwingUtilities.invokeLater`, you ensure that the `updateResults()` call, which updates the results, happens on the main UI thread (AWT event dispatching thread).

However, if you try to load the contributors via the `BACKGROUND` option, you can see that the list is updated but nothing changes in UI.

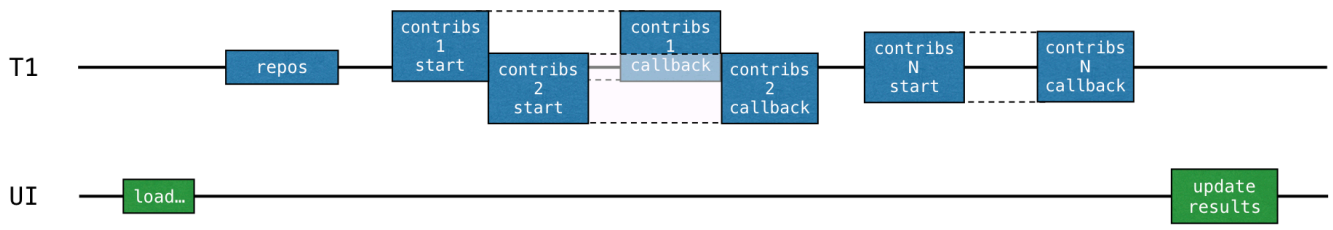
Task 2

Fix the `loadContributorsBackground()` function in `src/tasks/Request2Background.kt` so that the resulting list is shown in the UI.

Solution for task 2

If you try to load the contributors, you can see in the log that the contributors are loaded but the result isn't displayed. To fix this, call `updateResults()` on the resulting list of users:

```
thread {
    updateResults(loadContributorsBlocking(service, req))
}
```



Make sure to call the logic passed in the callback explicitly. Otherwise, nothing will happen.

Use the Retrofit callback API

In the previous solution, the whole loading logic is moved to the background thread, but that still isn't the best use of resources. All of the loading requests go sequentially and the thread is blocked while waiting for the loading result, while it could have been occupied by other tasks. Specifically, the thread could start loading another request to receive the entire result earlier.

Handling the data for each repository should then be divided into two parts: loading and processing the resulting response. The second *processing* part should be extracted into a callback.

The loading for each repository can then be started before the result for the previous repository is received (and the corresponding callback is called):

Using callback API

The Retrofit callback API can help achieve this. The `Call.enqueue()` function starts an HTTP request and takes a callback as an argument. In this callback, you need to specify what needs to be done after each request.

Open `src/tasks/Request3Callbacks.kt` and see the implementation of `loadContributorsCallbacks()` that uses this API:

```
fun loadContributorsCallbacks(
    service: GitHubService, req: RequestData,
    updateResults: (List<User>) -> Unit
) {
    service.getOrgReposCall(req.org).onResponse { responseRepos ->  // #1
        logRepos(req, responseRepos)
        val repos = responseRepos.bodyList()

        val allUsers = mutableListOf<User>()
        for (repo in repos) {
            service.getRepoContributorsCall(req.org, repo.name)
                .onResponse { responseUsers ->  // #2
                    logUsers(repo, responseUsers)
                    val users = responseUsers.bodyList()
                    allUsers += users
                }
        }
        // TODO: Why doesn't this code work? How to fix that?
        updateResults(allUsers.aggregate())
    }
```

- For convenience, this code fragment uses the `onResponse()` extension function declared in the same file. It takes a lambda as an argument rather than an object expression.
- The logic for handling the responses is extracted into callbacks: the corresponding lambdas start at lines `#1` and `#2`.

However, the provided solution doesn't work. If you run the program and load contributors by choosing the *CALLBACKS* option, you'll see that nothing is shown. However, the test from `Request3CallbacksKtTest` immediately returns the result that it successfully passed.

Think about why the given code doesn't work as expected and try to fix it, or see the solutions below.

Task 3 (optional)

Rewrite the code in the `src/tasks/Request3Callbacks.kt` file so that the loaded list of contributors is shown.

The first attempted solution for task 3

In the current solution, many requests are started concurrently, which decreases the total loading time. However, the result isn't loaded. This is because the `updateResults()` callback is called right after all of the loading requests are started, before the `allUsers` list has been filled with the data.

You could try to fix this with a change like the following:

```
val allUsers = mutableListOf<User>()
for ((index, repo) in repos.withIndex()) {   // #1
    service.getRepoContributorsCall(req.org, repo.name)
        .onResponse { responseUsers ->
            logUsers(repo, responseUsers)
            val users = responseUsers.bodyList()
            allUsers += users
            if (index == repos.lastIndex) {    // #2
                updateResults(allUsers.aggregate())
            }
        }
}
```

- First, you iterate over the list of repos with an index (`#1`).
- Then, from each callback, you check whether it's the last iteration (`#2`).
- And if that's the case, the result is updated.

However, this code also fails to achieve our objective. Try to find the answer yourself, or see the solution below.

The second attempted solution for task 3

Since the loading requests are started concurrently, there's no guarantee that the result for the last one comes last. The results can come in any order.

Thus, if you compare the current index with the `lastIndex` as a condition for completion, you risk losing the results for some repos.

If the request that processes the last repo returns faster than some prior requests (which is likely to happen), all of the results for requests that take more time will be lost.

One way to fix this is to introduce an index and check whether all of the repositories have already been processed:

```
val allUsers = Collections.synchronizedList(mutableListOf<User>())
val numberOfProcessed = AtomicInteger()
for (repo in repos) {
    service.getRepoContributorsCall(req.org, repo.name)
        .onResponse { responseUsers ->
            logUsers(repo, responseUsers)
            val users = responseUsers.bodyList()
            allUsers += users
            if (numberOfProcessed.incrementAndGet() == repos.size) {
                updateResults(allUsers.aggregate())
            }
        }
}
```

This code uses a synchronized version of the list and `AtomicInteger()` because, in general, there's no guarantee that different callbacks that process `getRepoContributors()` requests will always be called from the same thread.

The third attempted solution for task 3

An even better solution is to use the `CountDownLatch` class. It stores a counter initialized with the number of repositories. This counter is decremented after processing each repository. It then waits until the latch is counted down to zero before updating the results:

```
val countDownLatch = CountDownLatch(repos.size)
for (repo in repos) {
    service.getRepoContributorsCall(req.org, repo.name)
        .onResponse { responseUsers ->
            // processing repository
            countDownLatch.countDown()
        }
}
countDownLatch.await()
updateResults(allUsers.aggregate())
```

The result is then updated from the main thread. This is more direct than delegating the logic to the child threads.

After reviewing these three attempts at a solution, you can see that writing correct code with callbacks is non-trivial and error-prone, especially when several underlying threads and synchronization occur.

> As an additional exercise, you can implement the same logic using a reactive approach with the RxJava library. All of the necessary dependencies and solutions for using RxJava can be found in a separate `rx` branch. It is also possible to complete this tutorial and implement or check the proposed Rx versions for a proper comparison.

Suspending functions

You can implement the same logic using suspending functions. Instead of returning `Call<List<Repo>>`, define the API call as a suspending function as follows:

```
interface GitHubService {
    @GET("orgs/{org}/repos?per_page=100")
    suspend fun getOrgRepos(
        @Path("org") org: String
    ): List<Repo>
}
```

- `getOrgRepos()` is defined as a `suspend` function. When you use a suspending function to perform a request, the underlying thread isn't blocked. More details about how this works will come in later sections.
- `getOrgRepos()` returns the result directly instead of returning a `Call`. If the result is unsuccessful, an exception is thrown.

Alternatively, Retrofit allows returning the result wrapped in `Response`. In this case, the result body is provided, and it is possible to check for errors manually. This tutorial uses the versions that return `Response`.

In `src/contributors/GitHubService.kt`, add the following declarations to the `GitHubService` interface:

```
interface GitHubService {
    // getOrgReposCall & getRepoContributorsCall declarations

    @GET("orgs/{org}/repos?per_page=100")
    suspend fun getOrgRepos(
        @Path("org") org: String
    ): Response<List<Repo>>

    @GET("repos/{owner}/{repo}/contributors?per_page=100")
    suspend fun getRepoContributors(
        @Path("owner") owner: String,
        @Path("repo") repo: String
    ): Response<List<User>>
}
```

Task 4

Your task is to change the code of the function that loads contributors to make use of two new suspending functions, `getOrgRepos()` and `getRepoContributors()`. The new `loadContributorsSuspend()` function is marked as `suspend` to use the new API.

> Suspending functions can't be called everywhere. Calling a suspending function from `loadContributorsBlocking()` will result in an error with the message "Suspend function 'getOrgRepos' should be called only from a coroutine or another suspend function".

1. Copy the implementation of `loadContributorsBlocking()` that is defined in `src/tasks/Request1Blocking.kt` into the `loadContributorsSuspend()` that is defined in `src/tasks/Request4Suspend.kt`.
2. Modify the code so that the new suspending functions are used instead of the ones that return `Call`s.
3. Run the program by choosing the *SUSPEND* option and ensure that the UI is still responsive while the GitHub requests are performed.

Solution for task 4

Replace `.getOrgReposCall(req.org).execute()` with `.getOrgRepos(req.org)` and repeat the same replacement for the second "contributors" request:

```
suspend fun loadContributorsSuspend(service: GitHubService, req: RequestData): List<User> {
    val repos = service
        .getOrgRepos(req.org)
        .also { logRepos(req, it) }
        .bodyList()

    return repos.flatMap { repo ->
        service.getRepoContributors(req.org, repo.name)
            .also { logUsers(repo, it) }
            .bodyList()
    }.aggregate()
}
```

- `loadContributorsSuspend()` should be defined as a `suspend` function.
-

You no longer need to call `execute`, which returned the `Response` before, because now the API functions return the `Response` directly. Note that this detail is specific to the Retrofit library. With other libraries, the API will be different, but the concept is the same.

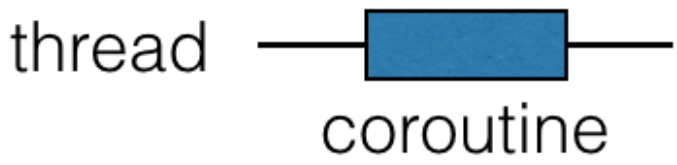
Coroutines

The code with suspending functions looks similar to the "blocking" version. The major difference from the blocking version is that instead of blocking the thread, the coroutine is suspended:

```
block → suspend
thread → coroutine
```

Coroutines are often called lightweight threads because you can run code on coroutines, similar to how you run code on threads. The operations that were blocking before (and had to be avoided) can now suspend the coroutine instead.

Starting a new coroutine

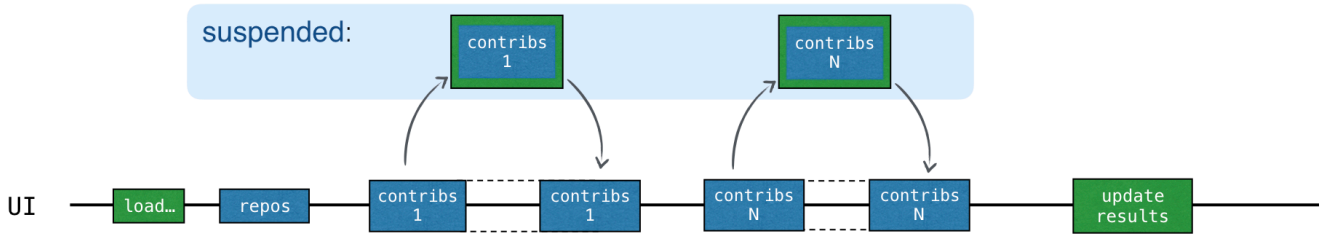


If you look at how `loadContributorsSuspend()` is used in `src/contributors/Contributors.kt`, you can see that it's called inside `launch`. `launch` is a library function that takes a lambda as an argument:

```
launch {
    val users = loadContributorsSuspend(req)
    updateResults(users, startTime)
}
```

Here `launch` starts a new computation that is responsible for loading the data and showing the results. The computation is suspendable – when performing network requests, it is suspended and releases the underlying thread. When the network request returns the result, the computation is resumed.

Such a suspendable computation is called a *coroutine*. So, in this case, `launch` *starts a new coroutine* responsible for loading data and showing the results.

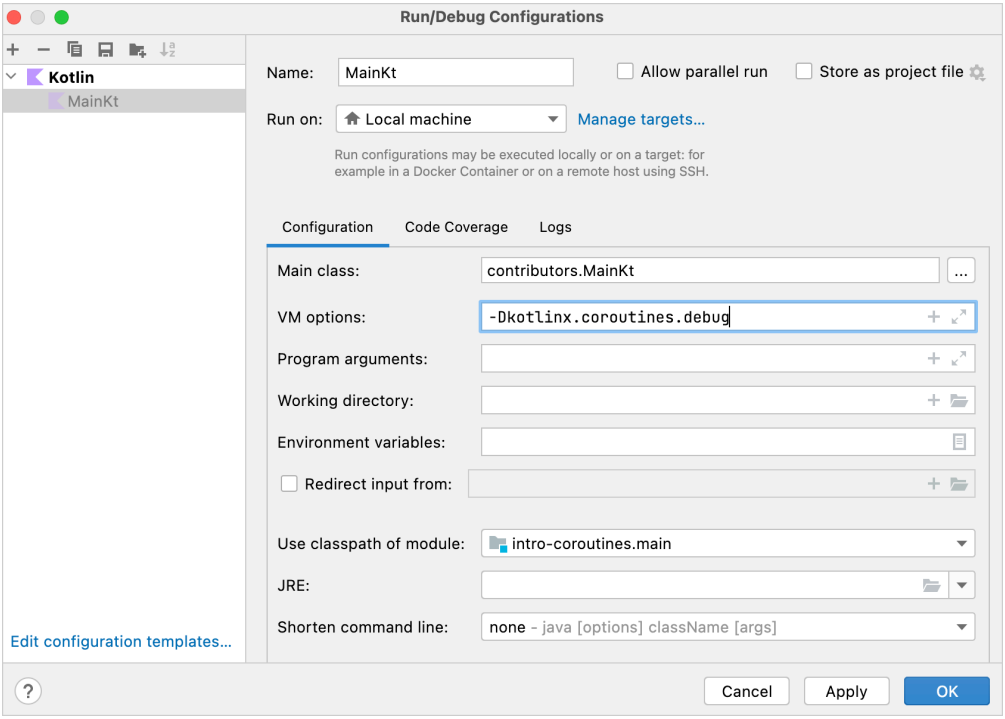


Coroutines run on top of threads and can be suspended. When a coroutine is suspended, the corresponding computation is paused, removed from the thread, and stored in memory. Meanwhile, the thread is free to be occupied by other tasks:

When the computation is ready to be continued, it is returned to a thread (not necessarily the same one).

In the `loadContributorsSuspend()` example, each "contributors" request now waits for the result using the suspension mechanism. First, the new request is sent. Then, while waiting for the response, the whole "load contributors" coroutine that was started by the `launch` function is suspended.

The coroutine resumes only after the corresponding response is received:



Suspending request

While the response is waiting to be received, the thread is free to be occupied by other tasks. The UI stays responsive, despite all the requests taking place on the main UI thread:

1. Run the program using the *SUSPEND* option. The log confirms that all of the requests are sent from the main UI thread:

```
2538 [AWT-EventQueue-0 @coroutine#1] INFO  Contributors - kotlin: loaded 30 repos
2729 [AWT-EventQueue-0 @coroutine#1] INFO  Contributors - ts2kt: loaded 11 contributors
3029 [AWT-EventQueue-0 @coroutine#1] INFO  Contributors - kotlin-koans: loaded 45 contributors
...
11252 [AWT-EventQueue-0 @coroutine#1] INFO  Contributors - kotlin-coroutines-workshop: loaded 1
contributors
```

2. The log can show you which coroutine the corresponding code is running on. To enable it, open **Run | Edit configurations** and add the `-Dkotlinx.coroutines.debug` VM option:

Edit run configuration

The coroutine name will be attached to the thread name while `main()` is run with this option. You can also modify the template for running all of the Kotlin files and enable this option by default.

Now all of the code runs on one coroutine, the "load contributors" coroutine mentioned above, denoted as `@coroutine#1`. While waiting for the result, you shouldn't reuse the thread for sending other requests because the code is written sequentially. The new request is sent only when the previous result is received.

Suspending functions treat the thread fairly and don't block it for "waiting". However, this doesn't yet bring any concurrency into the picture.

Concurrency

Kotlin coroutines are much less resource-intensive than threads. Each time you want to start a new computation asynchronously, you can create a new coroutine instead.

To start a new coroutine, use one of the main *coroutine builders*: `launch`, `async`, or `runBlocking`. Different libraries can define additional coroutine builders.

`async` starts a new coroutine and returns a `Deferred` object. `Deferred` represents a concept known by other names such as `Future` or `Promise`. It stores a computation, but it *defers* the moment you get the final result; it *promises* the result sometime in the *future*.

The main difference between `async` and `launch` is that `launch` is used to start a computation that isn't expected to return a specific result. `launch` returns a `Job` that represents the coroutine. It is possible to wait until it completes by calling `Job.join()`.

`Deferred` is a generic type that extends `Job`. An `async` call can return a `Deferred<Int>` or a `Deferred<CustomType>`, depending on what the lambda returns (the last expression inside the lambda is the result).

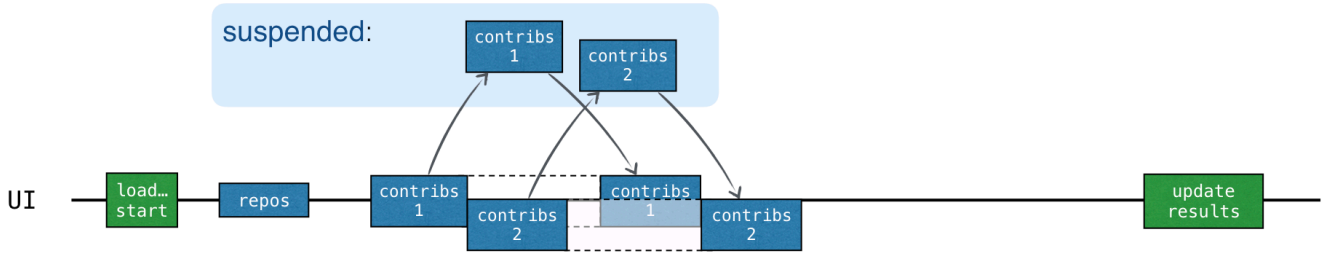
To get the result of a coroutine, you can call `await()` on the `Deferred` instance. While waiting for the result, the coroutine that this `await()` is called from is suspended:

```
import kotlinx.coroutines.*

fun main() = runBlocking {
    val deferred: Deferred<Int> = async {
        loadData()
    }
    println("waiting...")
    println(deferred.await())
}

suspend fun loadData(): Int {
    println("loading...")
    delay(1000L)
    println("loaded!")
    return 42
}
```

`runBlocking` is used as a bridge between regular and suspending functions, or between the blocking and non-blocking worlds. It works as an adaptor for starting the top-level main coroutine. It is intended primarily to be used in `main()` functions and tests.



Watch this video for a better understanding of coroutines.

If there is a list of deferred objects, you can call `awaitAll()` to await the results of all of them:

```
import kotlinx.coroutines.*

fun main() = runBlocking {
    val deferreds: List<Deferred<Int>> = (1..3).map {
        async {
            delay(1000L * it)
            println("Loading $it")
            it
        }
    }
    val sum = deferreds.awaitAll().sum()
    println("$sum")
}
```

When each "contributors" request is started in a new coroutine, all of the requests are started asynchronously. A new request can be sent before the result for the previous one is received:

Concurrent coroutines

The total loading time is approximately the same as in the *CALLBACKS* version, but it doesn't need any callbacks. What's more, `async` explicitly emphasizes which parts run concurrently in the code.

Task 5

In the `Request5Concurrent.kt` file, implement a `loadContributorsConcurrent()` function by using the previous `loadContributorsSuspend()` function.

Tip for task 5

You can only start a new coroutine inside a coroutine scope. Copy the content from `loadContributorsSuspend()` to the `coroutineScope` call so that you can call `async` functions there:

```
suspend fun loadContributorsConcurrent(
    service: GitHubService,
    req: RequestData
): List<User> = coroutineScope {
    // ...
}
```

Base your solution on the following scheme:

```
val deferreds: List<Deferred<List<User>>> = repos.map { repo ->
    async {
        // load contributors for each repo
    }
}
deferreds.awaitAll() // List<List<User>>
```

Solution for task 5

Wrap each "contributors" request with `async` to create as many coroutines as there are repositories. `async` returns `Deferred<List<User>>`. This is not an issue because creating new coroutines is not very resource-intensive, so you can create as many as you need.

1. You can no longer use `flatMap` because the `map` result is now a list of `Deferred` objects, not a list of lists. `awaitAll()` returns `List<List<User>>`, so call `flatten().aggregate()` to get the result:

   ```
   suspend fun loadContributorsConcurrent(
       service: GitHubService,
       req: RequestData
   ): List<User> = coroutineScope {
       val repos = service
           .getOrgRepos(req.org)
           .also { logRepos(req, it) }
           .bodyList()

       val deferreds: List<Deferred<List<User>>> = repos.map { repo ->
           async {
               service.getRepoContributors(req.org, repo.name)
                   .also { logUsers(repo, it) }
                   .bodyList()
           }
       }
       deferreds.awaitAll().flatten().aggregate()
   }
   ```

2. Run the code and check the log. All of the coroutines still run on the main UI thread because multithreading hasn't been employed yet, but you can already see the benefits of running coroutines concurrently.

3. To change this code to run "contributors" coroutines on different threads from the common thread pool, specify `Dispatchers.Default` as the context argument for the `async` function:

```
async(Dispatchers.Default) { }
```

- `CoroutineDispatcher` determines what thread or threads the corresponding coroutine should be run on. If you don't specify one as an argument, `async` will use the dispatcher from the outer scope.
- `Dispatchers.Default` represents a shared pool of threads on the JVM. This pool provides a means for parallel execution. It consists of as many threads as there are CPU cores available, but it will still have two threads if there's only one core.

4. Modify the code in the `loadContributorsConcurrent()` function to start new coroutines on different threads from the common thread pool. Also, add additional logging before sending the request:

```
async(Dispatchers.Default) {
    log("starting loading for ${repo.name}")
    service.getRepoContributors(req.org, repo.name)
        .also { logUsers(repo, it) }
        .bodyList()
}
```

5. Run the program once again. In the log, you can see that each coroutine can be started on one thread from the thread pool and resumed on another:

```
1946 [DefaultDispatcher-worker-2 @coroutine#4] INFO  Contributors - starting loading for kotlin-
koans
1946 [DefaultDispatcher-worker-3 @coroutine#5] INFO  Contributors - starting loading for dokka
1946 [DefaultDispatcher-worker-1 @coroutine#3] INFO  Contributors - starting loading for ts2kt
...
2178 [DefaultDispatcher-worker-1 @coroutine#4] INFO  Contributors - kotlin-koans: loaded 45
contributors
2569 [DefaultDispatcher-worker-1 @coroutine#5] INFO  Contributors - dokka: loaded 36 contributors
2821 [DefaultDispatcher-worker-2 @coroutine#3] INFO  Contributors - ts2kt: loaded 11 contributors
```

For instance, in this log excerpt, `coroutine#4` is started on the `worker-2` thread and continued on the `worker-1` thread.

In `src/contributors/Contributors.kt`, check the implementation of the *CONCURRENT* option:

1. To run the coroutine only on the main UI thread, specify `Dispatchers.Main` as an argument:

```
launch(Dispatchers.Main) {
    updateResults()
}
```

- If the main thread is busy when you start a new coroutine on it, the coroutine becomes suspended and scheduled for execution on this thread. The coroutine will only resume when the thread becomes free.
- It's considered good practice to use the dispatcher from the outer scope rather than explicitly specifying it on each end-point. If you define `loadContributorsConcurrent()` without passing `Dispatchers.Default` as an argument, you can call this function in any context: with a `Default` dispatcher, with the main UI thread, or with a custom dispatcher.
- As you'll see later, when calling `loadContributorsConcurrent()` from tests, you can call it in the context with `TestDispatcher`, which simplifies testing. That makes this solution much more flexible.

2. To specify the dispatcher on the caller side, apply the following change to the project while letting `loadContributorsConcurrent` start coroutines in the inherited context:

```
launch(Dispatchers.Default) {
    val users = loadContributorsConcurrent(service, req)
    withContext(Dispatchers.Main) {
        updateResults(users, startTime)
    }
}
```

   - `updateResults()` should be called on the main UI thread, so you call it with the context of `Dispatchers.Main`.
   - `withContext()` calls the given code with the specified coroutine context, is suspended until it completes, and returns the result. An alternative but more verbose way to express this would be to start a new coroutine and explicitly wait (by suspending) until it completes: `launch(context) { ... }.join()`.

3. Run the code and ensure that the coroutines are executed on the threads from the thread pool.

Structured concurrency

- The *coroutine scope* is responsible for the structure and parent-child relationships between different coroutines. New coroutines usually need to be started inside a scope.
- The *coroutine context* stores additional technical information used to run a given coroutine, like the coroutine custom name, or the dispatcher specifying the threads the coroutine should be scheduled on.

When `launch`, `async`, or `runBlocking` are used to start a new coroutine, they automatically create the corresponding scope. All of these functions take a lambda with a receiver as an argument, and `CoroutineScope` is the implicit receiver type:

```
launch { /* this: CoroutineScope */ }
```

- New coroutines can only be started inside a scope.
- `launch` and `async` are declared as extensions to `CoroutineScope`, so an implicit or explicit receiver must always be passed when you call them.
- The coroutine started by `runBlocking` is the only exception because `runBlocking` is defined as a top-level function. But because it blocks the current thread, it's intended primarily to be used in `main()` functions and tests as a bridge function.

A new coroutine inside `runBlocking`, `launch`, or `async` is started automatically inside the scope:

```
import kotlinx.coroutines.*

fun main() = runBlocking { /* this: CoroutineScope */
    launch { /* ... */ }
    // the same as:
    this.launch { /* ... */ }
}
```

When you call `launch` inside `runBlocking`, it's called as an extension to the implicit receiver of the `CoroutineScope` type. Alternatively, you could explicitly write `this.launch`.

The nested coroutine (started by `launch` in this example) can be considered as a child of the outer coroutine (started by `runBlocking`). This "parent-child" relationship works through scopes; the child coroutine is started from the scope corresponding to the parent coroutine.

It's possible to create a new scope without starting a new coroutine, by using the `coroutineScope` function. To start new coroutines in a structured way inside a `suspend` function without access to the outer scope, you can create a new coroutine scope that automatically becomes a child of the outer scope that this `suspend` function is called from. `loadContributorsConcurrent()` is a good example.

You can also start a new coroutine from the global scope using `GlobalScope.async` or `GlobalScope.launch`. This will create a top-level "independent" coroutine.

The mechanism behind the structure of the coroutines is called *structured concurrency*. It provides the following benefits over global scopes:

- The scope is generally responsible for child coroutines, whose lifetime is attached to the lifetime of the scope.
- The scope can automatically cancel child coroutines if something goes wrong or a user changes their mind and decides to revoke the operation.
- The scope automatically waits for the completion of all child coroutines. Therefore, if the scope corresponds to a coroutine, the parent coroutine does not complete until all the coroutines launched in its scope have completed.

When using `GlobalScope.async`, there is no structure that binds several coroutines to a smaller scope. Coroutines started from the global scope are all independent – their lifetime is limited only by the lifetime of the whole application. It's possible to store a reference to the coroutine started from the global scope and wait for its completion or cancel it explicitly, but that won't happen automatically as it would with structured concurrency.

Canceling the loading of contributors

Create two versions of the function that loads the list of contributors. Compare how both versions behave when you try to cancel the parent coroutine. The first version will use `coroutineScope` to start all of the child coroutines, whereas the second will use `GlobalScope`.

1. In `Request5Concurrent.kt`, add a 3-second delay to the `loadContributorsConcurrent()` function:

   ```
   suspend fun loadContributorsConcurrent(
       service: GitHubService,
       req: RequestData
   ): List<User> = coroutineScope {
       // ...
       async {
           log("starting loading for ${repo.name}")
           delay(3000)
           // load repo contributors
       }
       // ...
   }
   ```

   The delay affects all of the coroutines that send requests, so that there's enough time to cancel the loading after the coroutines are started but before the requests are sent.

2. Create the second version of the loading function: copy the implementation of `loadContributorsConcurrent()` to `loadContributorsNotCancellable()` in `Request5NotCancellable.kt` and then remove the creation of a new `coroutineScope`.

3. The `async` calls now fail to resolve, so start them by using `GlobalScope.async`:

```
suspend fun loadContributorsNotCancellable(
    service: GitHubService,
    req: RequestData
): List<User> {   // #1
    // ...
    GlobalScope.async {   // #2
        log("starting loading for ${repo.name}")
        // load repo contributors
    }
    // ...
    return deferreds.awaitAll().flatten().aggregate()  // #3
}
```

- The function now returns the result directly, not as the last expression inside the lambda (lines `#1` and `#3`).
- All of the "contributors" coroutines are started inside the `GlobalScope`, not as children of the coroutine scope (line `#2`).

4. Run the program and choose the *CONCURRENT* option to load the contributors.
5. Wait until all of the "contributors" coroutines are started, and then click *Cancel*. The log shows no new results, which means that all of the requests were indeed canceled:

```
2896 [AWT-EventQueue-0 @coroutine#1] INFO  Contributors - kotlin: loaded 40 repos
2901 [DefaultDispatcher-worker-2 @coroutine#4] INFO  Contributors - starting loading for kotlin-
koans
...
2909 [DefaultDispatcher-worker-5 @coroutine#36] INFO  Contributors - starting loading for mpp-
example
/* click on 'cancel' */
/* no requests are sent */
```

6. Repeat step 5, but this time choose the `NOT_CANCELLABLE` option:

```
2570 [AWT-EventQueue-0 @coroutine#1] INFO  Contributors - kotlin: loaded 30 repos
2579 [DefaultDispatcher-worker-1 @coroutine#4] INFO  Contributors - starting loading for kotlin-
koans
...
2586 [DefaultDispatcher-worker-6 @coroutine#36] INFO  Contributors - starting loading for mpp-
example
/* click on 'cancel' */
/* but all the requests are still sent: */
6402 [DefaultDispatcher-worker-5 @coroutine#4] INFO  Contributors - kotlin-koans: loaded 45
contributors
...
9555 [DefaultDispatcher-worker-8 @coroutine#36] INFO  Contributors - mpp-example: loaded 8
contributors
```

   In this case, no coroutines are canceled, and all the requests are still sent.

7. Check how the cancellation is triggered in the "contributors" program. When the *Cancel* button is clicked, the main "loading" coroutine is explicitly canceled and the child coroutines are canceled automatically:

```
interface Contributors {

    fun loadContributors() {
        // ...
        when (getSelectedVariant()) {
            CONCURRENT -> {
                launch {
                    val users = loadContributorsConcurrent(service, req)
                    updateResults(users, startTime)
                }.setUpCancellation()      // #1
            }
        }
    }

    private fun Job.setUpCancellation() {
        val loadingJob = this              // #2

        // cancel the loading job if the 'cancel' button was clicked:
        val listener = ActionListener {
            loadingJob.cancel()            // #3
            updateLoadingStatus(CANCELED)
        }
        // add a listener to the 'cancel' button:
        addCancelListener(listener)

        // update the status and remove the listener
        // after the loading job is completed
    }
}
```

The `launch` function returns an instance of `Job`. `Job` stores a reference to the "loading coroutine", which loads all of the data and updates the results. You can call the `setUpCancellation()` extension function on it (line `#1`), passing an instance of `Job` as a receiver.

Another way you could express this would be to explicitly write:

```
val job = launch { }
job.setUpCancellation()
```

- For readability, you could refer to the `setUpCancellation()` function receiver inside the function with the new `loadingJob` variable (line `#2`).
- Then you could add a listener to the *Cancel* button so that when it's clicked, the `loadingJob` is canceled (line `#3`).

With structured concurrency, you only need to cancel the parent coroutine and this automatically propagates cancellation to all of the child coroutines.

Using the outer scope's context

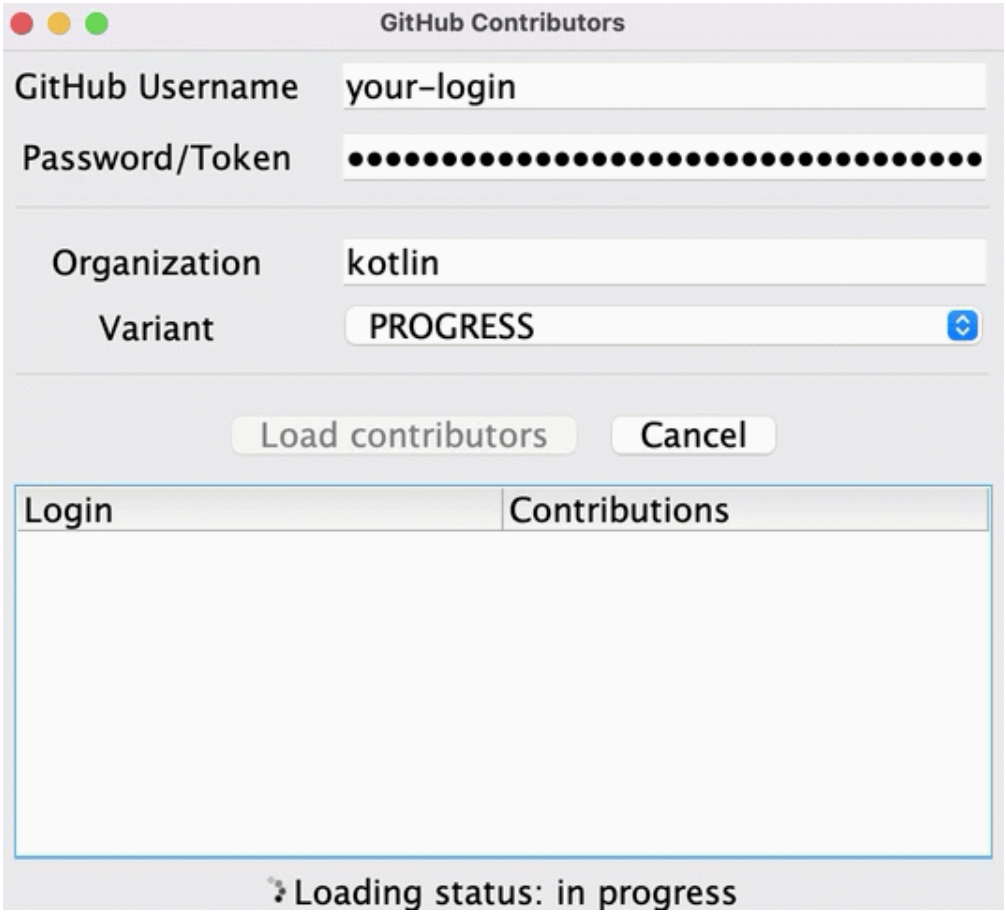
When you start new coroutines inside the given scope, it's much easier to ensure that all of them run with the same context. It is also much easier to replace the context if needed.

Now it's time to learn how using the dispatcher from the outer scope works. The new scope created by the `coroutineScope` or by the coroutine builders always inherits the context from the outer scope. In this case, the outer scope is the scope the `suspend loadContributorsConcurrent()` function was called from:

```
launch(Dispatchers.Default) {  // outer scope
    val users = loadContributorsConcurrent(service, req)
    // ...
}
```

All of the nested coroutines are automatically started with the inherited context. The dispatcher is a part of this context. That's why all of the coroutines started by `async` are started with the context of the default dispatcher:

```
suspend fun loadContributorsConcurrent(
    service: GitHubService, req: RequestData
): List<User> = coroutineScope {
    // this scope inherits the context from the outer scope
    // ...
    async {   // nested coroutine started with the inherited context
        // ...
    }
    // ...
}
```



With structured concurrency, you can specify the major context elements (like dispatcher) once, when creating the top-level coroutine. All the nested coroutines then inherit the context and modify it only if needed.

When you write code with coroutines for UI applications, for example Android ones, it's a common practice to use `CoroutineDispatchers.Main` by default for the top coroutine and then to explicitly put a different dispatcher when you need to run the code on a different thread.

Showing progress

Despite the information for some repositories being loaded rather quickly, the user only sees the resulting list after all of the data has been loaded. Until then, the loader icon runs showing the progress, but there's no information about the current state or what contributors are already loaded.

You can show the intermediate results earlier and display all of the contributors after loading the data for each of the repositories:

To implement this functionality, in the `src/tasks/Request6Progress.kt`, you'll need to pass the logic updating the UI as a callback, so that it's called on each intermediate state:

```
suspend fun loadContributorsProgress(
    service: GitHubService,
    req: RequestData,
    updateResults: suspend (List<User>, completed: Boolean) -> Unit
) {
    // loading the data
    // calling `updateResults()` on intermediate states
}
```

On the call site in `Contributors.kt`, the callback is passed to update the results from the `Main` thread for the *PROGRESS* option:

```
launch(Dispatchers.Default) {
    loadContributorsProgress(service, req) { users, completed ->
        withContext(Dispatchers.Main) {
            updateResults(users, startTime, completed)
        }
    }
}
```

- The `updateResults()` parameter is declared as `suspend` in `loadContributorsProgress()`. It's necessary to call `withContext`, which is a `suspend` function inside the corresponding lambda argument.
- `updateResults()` callback takes an additional Boolean parameter as an argument specifying whether the loading has completed and the results are final.

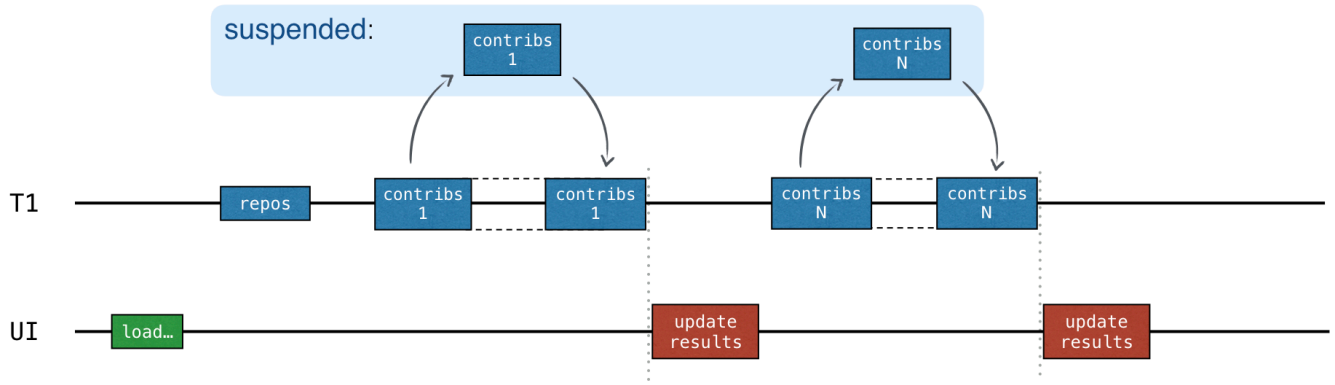
Task 6

In the `Request6Progress.kt` file, implement the `loadContributorsProgress()` function that shows the intermediate progress. Base it on the `loadContributorsSuspend()` function from `Request4Suspend.kt`.

- Use a simple version without concurrency; you'll add it later in the next section.
- The intermediate list of contributors should be shown in an "aggregated" state, not just the list of users loaded for each repository.
- The total number of contributions for each user should be increased when the data for each new repository is loaded.

Solution for task 6

To store the intermediate list of loaded contributors in the "aggregated" state, define an `allUsers` variable which stores the list of users, and then update it after contributors for each new repository are loaded:

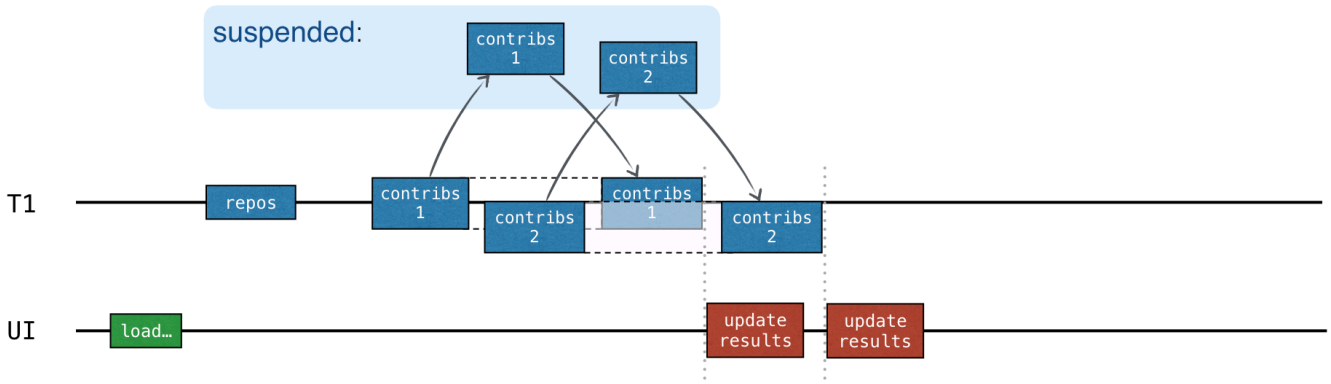


```
suspend fun loadContributorsProgress(
    service: GitHubService,
    req: RequestData,
    updateResults: suspend (List<User>, completed: Boolean) -> Unit
) {
    val repos = service
        .getOrgRepos(req.org)
        .also { logRepos(req, it) }
        .bodyList()

    var allUsers = emptyList<User>()
    for ((index, repo) in repos.withIndex()) {
        val users = service.getRepoContributors(req.org, repo.name)
            .also { logUsers(repo, it) }
            .bodyList()

        allUsers = (allUsers + users).aggregate()
        updateResults(allUsers, index == repos.lastIndex)
    }
}
```

Consecutive vs concurrent



An `updateResults()` callback is called after each request is completed:

Progress on requests

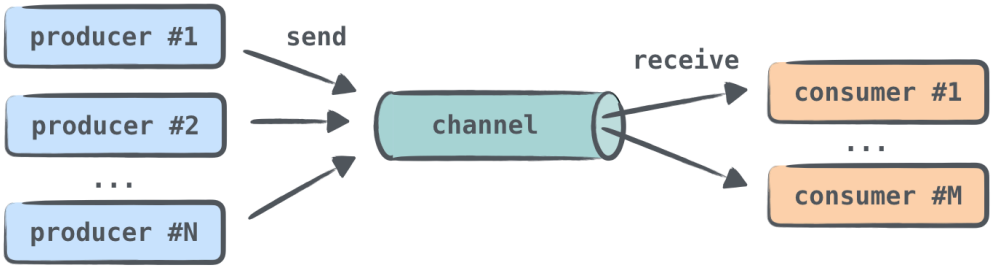
This code doesn't include concurrency. It's sequential, so you don't need synchronization.

The best option would be to send requests concurrently and update the intermediate results after getting the response for each repository:

Concurrent requests

To add concurrency, use *channels*.

Channels



Writing code with a shared mutable state is quite difficult and error-prone (like in the solution using callbacks). A simpler way is to share information by communication rather than by using a common mutable state. Coroutines can communicate with each other through *channels*.

Channels are communication primitives that allow data to be passed between coroutines. One coroutine can *send* some information to a channel, while another can *receive* that information from it:

Using channels

A coroutine that sends (produces) information is often called a producer, and a coroutine that receives (consumes) information is called a consumer. One or multiple coroutines can send information to the same channel, and one or multiple coroutines can receive data from it:

Using channels with many coroutines

When many coroutines receive information from the same channel, each element is handled only once by one of the consumers. Once an element is handled, it is immediately removed from the channel.

You can think of a channel as similar to a collection of elements, or more precisely, a queue, in which elements are added to one end and received from the other. However, there's an important difference: unlike collections, even in their synchronized versions, a channel can *suspend* `send()` and `receive()` operations. This happens when the channel is empty or full. The channel can be full if the channel size has an upper bound.

`Channel` is represented by three different interfaces: `SendChannel`, `ReceiveChannel`, and `Channel`, with the latter extending the first two. You usually create a channel and give it to producers as a `SendChannel` instance so that only they can send information to the channel. You give a channel to consumers as a `ReceiveChannel` instance so that only they can receive from it. Both `send` and `receive` methods are declared as `suspend`:

```
interface SendChannel<in E> {
    suspend fun send(element: E)
    fun close(): Boolean
}

interface ReceiveChannel<out E> {
    suspend fun receive(): E
}

interface Channel<E> : SendChannel<E>, ReceiveChannel<E>
```

The producer can close a channel to indicate that no more elements are coming.

Several types of channels are defined in the library. They differ in how many elements they can internally store and whether the `send()` call can be suspended or not. For all of the channel types, the `receive()` call behaves similarly: it receives an element if the channel is not empty; otherwise, it is suspended.

Unlimited channel

An unlimited channel is the closest analog to a queue: producers can send elements to this channel and it will keep growing indefinitely. The `send()` call will never be suspended. If the program runs out of memory, you'll get an `OutOfMemoryException`. The difference between an unlimited channel and a queue is that when a consumer tries to receive from an empty channel, it becomes suspended until some new elements are sent.

Unlimited channel

Buffered channel

The size of a buffered channel is constrained by the specified number. Producers can send elements to this channel until the size limit is reached. All of the elements are internally stored. When the channel is full, the next `send()` call on it is suspended until more free space becomes available.

Buffered channel

Rendezvous channel

The "Rendezvous" channel is a channel without a buffer, the same as a buffered channel with zero size. One of the functions (`send()` or `receive()`) is always suspended until the other is called.

If the `send()` function is called and there's no suspended `receive()` call ready to process the element, then `send()` is suspended. Similarly, if the `receive()` function is called and the channel is empty or, in other words, there's no suspended `send()` call ready to send the element, the `receive()` call is suspended.

The "rendezvous" name ("a meeting at an agreed time and place") refers to the fact that `send()` and `receive()` should "meet on time".

Rendezvous channel

Conflated channel

A new element sent to the conflated channel will overwrite the previously sent element, so the receiver will always get only the latest element. The `send()` call is never suspended.

When you create a channel, specify its type or the buffer size (if you need a buffered one):

```
val rendezvousChannel = Channel<String>()
val bufferedChannel = Channel<String>(10)
val conflatedChannel = Channel<String>(CONFLATED)
val unlimitedChannel = Channel<String>(UNLIMITED)
```

By default, a "Rendezvous" channel is created.

In the following task, you'll create a "Rendezvous" channel, two producer coroutines, and a consumer coroutine:

```
import kotlinx.coroutines.channels.Channel
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    val channel = Channel<String>()
    launch {
        channel.send("A1")
        channel.send("A2")
        log("A done")
    }
    launch {
        channel.send("B1")
        log("B done")
    }
    launch {
        repeat(3) {
            val x = channel.receive()
            log(x)
        }
    }
}

fun log(message: Any?) {
    println("[${Thread.currentThread().name}] $message")
}
```

Watch this video for a better understanding of channels.

Task 7

In `src/tasks/Request7Channels.kt`, implement the function `loadContributorsChannels()` that requests all of the GitHub contributors concurrently and shows intermediate progress at the same time.

Use the previous functions, `loadContributorsConcurrent()` from `Request5Concurrent.kt` and `loadContributorsProgress()` from `Request6Progress.kt`.

Tip for task 7

Different coroutines that concurrently receive contributor lists for different repositories can send all of the received results to the same channel:

```
val channel = Channel<List<User>>()
for (repo in repos) {
    launch {
        val users = TODO()
        // ...
        channel.send(users)
    }
}
```

Then the elements from this channel can be received one by one and processed:

```
repeat(repos.size) {
    val users = channel.receive()
    // ...
}
```

Since the `receive()` calls are sequential, no additional synchronization is needed.

Solution for task 7

As with the `loadContributorsProgress()` function, you can create an `allUsers` variable to store the intermediate states of the "all contributors" list. Each new list received from the channel is added to the list of all users. You aggregate the result and update the state using the `updateResults` callback:

```
suspend fun loadContributorsChannels(
    service: GitHubService,
    req: RequestData,
    updateResults: suspend (List<User>, completed: Boolean) -> Unit
) = coroutineScope {

    val repos = service
        .getOrgRepos(req.org)
        .also { logRepos(req, it) }
        .bodyList()

    val channel = Channel<List<User>>()
    for (repo in repos) {
        launch {
            val users = service.getRepoContributors(req.org, repo.name)
                .also { logUsers(repo, it) }
                .bodyList()
            channel.send(users)
        }
    }
    var allUsers = emptyList<User>()
    repeat(repos.size) {
        val users = channel.receive()
        allUsers = (allUsers + users).aggregate()
        updateResults(allUsers, it == repos.lastIndex)
    }
}
```

- Results for different repositories are added to the channel as soon as they are ready. At first, when all of the requests are sent, and no data is received, the `receive()` call is suspended. In this case, the whole "load contributors" coroutine is suspended.
- Then, when the list of users is sent to the channel, the "load contributors" coroutine resumes, the `receive()` call returns this list, and the results are immediately updated.

You can now run the program and choose the *CHANNELS* option to load the contributors and see the result.

Although neither coroutines nor channels completely remove the complexity that comes with concurrency, they make life easier when you need to understand what's going on.

Testing coroutines

Let's now test all solutions to check that the solution with concurrent coroutines is faster than the solution with the `suspend` functions, and check that the solution with channels is faster than the simple "progress" one.

In the following task, you'll compare the total running time of the solutions. You'll mock a GitHub service and make this service return results after the given timeouts:

```
repos request - returns an answer within 1000 ms delay
repo-1 - 1000 ms delay
repo-2 - 1200 ms delay
repo-3 - 800 ms delay
```

The sequential solution with the `suspend` functions should take around 4000 ms (4000 = 1000 + (1000 + 1200 + 800)). The concurrent solution should take around 2200 ms (2200 = 1000 + max(1000, 1200, 800)).

For the solutions that show progress, you can also check the intermediate results with timestamps.

The corresponding test data is defined in `test/contributors/testData.kt`, and the files `Request4SuspendKtTest`, `Request7ChannelsKtTest`, and so on contain the straightforward tests that use mock service calls.

However, there are two problems here:

- These tests take too long to run. Each test takes around 2 to 4 seconds, and you need to wait for the results each time. It's not very efficient.
- You can't rely on the exact time the solution runs because it still takes additional time to prepare and run the code. You could add a constant, but then the time would differ from machine to machine. The mock service delays should be higher than this constant so you can see a difference. If the constant is 0.5 sec, making the delays 0.1 sec won't be enough.

A better way would be to use special frameworks to test the timing while running the same code several times (which increases the total time even more), but that is complicated to learn and set up.

To solve these problems and make sure that solutions with provided test delays behave as expected, one faster than the other, use *virtual* time with a special test dispatcher. This dispatcher keeps track of the virtual time passed from the start and runs everything immediately in real time. When you run coroutines on this dispatcher, the `delay` will return immediately and advance the virtual time.

Tests that use this mechanism run fast, but you can still check what happens at different moments in virtual time. The total running time drastically decreases:

Comparison for total running time

To use virtual time, replace the `runBlocking` invocation with a `runTest`. `runTest` takes an extension lambda to `TestScope` as an argument. When you call `delay` in a `suspend` function inside this special scope, `delay` will increase the virtual time instead of delaying in real time:

```
@Test
fun testDelayInSuspend() = runTest {
    val realStartTime = System.currentTimeMillis()
    val virtualStartTime = currentTime

    foo()
    println("${System.currentTimeMillis() - realStartTime} ms") // ~ 6 ms
    println("${currentTime - virtualStartTime} ms")             // 1000 ms
}

suspend fun foo() {
    delay(1000)    // auto-advances without delay
    println("foo") // executes eagerly when foo() is called
}
```

You can check the current virtual time using the `currentTime` property of `TestScope`.

The actual running time in this example is several milliseconds, whereas virtual time equals the delay argument, which is 1000 milliseconds.

To get the full effect of "virtual" `delay` in child coroutines, start all of the child coroutines with `TestDispatcher`. Otherwise, it won't work. This dispatcher is automatically inherited from the other `TestScope`, unless you provide a different dispatcher:

```
@Test
fun testDelayInLaunch() = runTest {
    val realStartTime = System.currentTimeMillis()
    val virtualStartTime = currentTime

    bar()

    println("${System.currentTimeMillis() - realStartTime} ms") // ~ 11 ms
    println("${currentTime - virtualStartTime} ms")             // 1000 ms
}

suspend fun bar() = coroutineScope {
    launch {
        delay(1000)    // auto-advances without delay
        println("bar") // executes eagerly when bar() is called
    }
}
```

If `launch` is called with the context of `Dispatchers.Default` in the example above, the test will fail. You'll get an exception saying that the job has not been completed yet.

You can test the `loadContributorsConcurrent()` function this way only if it starts the child coroutines with the inherited context, without modifying it using the `Dispatchers.Default` dispatcher.

You can specify the context elements like the dispatcher when *calling* a function rather than when *defining* it, which allows for more flexibility and easier testing.

The testing API that supports virtual time is Experimental and may change in the future.

By default, the compiler shows warnings if you use the experimental testing API. To suppress these warnings, annotate the test function or the whole class containing the tests with `@OptIn(ExperimentalCoroutinesApi::class)`. Add the compiler argument instructing the compiler that you're using the experimental API:

```
compileTestKotlin {
    kotlinOptions {
        freeCompilerArgs += "-Xuse-experimental=kotlin.Experimental"
    }
}
```

In the project corresponding to this tutorial, the compiler argument has already been added to the Gradle script.

Task 8

Refactor the following tests in `tests/tasks/` to use virtual time instead of real time:

- `Request4SuspendKtTest.kt`
- `Request5ConcurrentKtTest.kt`
- `Request6ProgressKtTest.kt`
- `Request7ChannelsKtTest.kt`

Compare the total running times before and after applying your refactoring.

Tip for task 8

1. Replace the `runBlocking` invocation with `runTest`, and replace `System.currentTimeMillis()` with `currentTime`:

```
@Test
fun test() = runTest {
    val startTime = currentTime
    // action
    val totalTime = currentTime - startTime
    // testing result
}
```

2. Uncomment the assertions that check the exact virtual time.

3. Don't forget to add `@UseExperimental(ExperimentalCoroutinesApi::class)`.

Solution for task 8

Here are the solutions for the concurrent and channels cases:

```
fun testConcurrent() = runTest {
    val startTime = currentTime
    val result = loadContributorsConcurrent(MockGithubService, testRequestData)
    Assert.assertEquals("Wrong result for 'loadContributorsConcurrent'",
expectedConcurrentResults.users, result)
    val totalTime = currentTime - startTime

    Assert.assertEquals(
        "The calls run concurrently, so the total virtual time should be 2200 ms: " +
                "1000 for repos request plus max(1000, 1200, 800) = 1200 for concurrent contributors
requests)",
        expectedConcurrentResults.timeFromStart, totalTime
    )
}
```

First, check that the results are available exactly at the expected virtual time, and then check the results themselves:

```
fun testChannels() = runTest {
    val startTime = currentTime
    var index = 0
    loadContributorsChannels(MockGithubService, testRequestData) { users, _ →
        val expected = concurrentProgressResults[index++]
        val time = currentTime - startTime
        Assert.assertEquals(
            "Expected intermediate results after ${expected.timeFromStart} ms:",
            expected.timeFromStart, time
        )
        Assert.assertEquals("Wrong intermediate results after $time:", expected.users, users)
    }
}
```

The first intermediate result for the last version with channels becomes available sooner than the progress version, and you can see the difference in tests that use virtual time.

The tests for the remaining "suspend" and "progress" tasks are very similar – you can find them in the project's `solutions` branch.

What's next

- Find out more about using virtual time and the experimental testing package.

Composing suspending functions

This section covers various approaches to composition of suspending functions.

Sequential by default

Assume that we have two suspending functions defined elsewhere that do something useful like some kind of remote service call or computation. We just pretend they are useful, but actually each one just delays for a second for the purpose of this example:

```
suspend fun doSomethingUsefulOne(): Int {
    delay(1000L) // pretend we are doing something useful here
    return 13
}

suspend fun doSomethingUsefulTwo(): Int {
    delay(1000L) // pretend we are doing something useful here, too
    return 29
}
```

What do we do if we need them to be invoked *sequentially* — first `doSomethingUsefulOne` *and then* `doSomethingUsefulTwo`, and compute the sum of their results? In practice, we do this if we use the result of the first function to make a decision on whether we need to invoke the second one or to decide on how to invoke it.

We use a normal sequential invocation, because the code in the coroutine, just like in the regular code, is *sequential* by default. The following example demonstrates it by measuring the total time it takes to execute both suspending functions:

```
import kotlinx.coroutines.*
import kotlin.system.*

fun main() = runBlocking<Unit> {
    val time = measureTimeMillis {
        val one = doSomethingUsefulOne()
        val two = doSomethingUsefulTwo()
        println("The answer is ${one + two}")
    }
    println("Completed in $time ms")
}

suspend fun doSomethingUsefulOne(): Int {
    delay(1000L) // pretend we are doing something useful here
    return 13
}

suspend fun doSomethingUsefulTwo(): Int {
    delay(1000L) // pretend we are doing something useful here, too
    return 29
}
```

You can get the full code here.

It produces something like this:

```
The answer is 42
Completed in 2017 ms
```

Concurrent using async

What if there are no dependencies between invocations of `doSomethingUsefulOne` and `doSomethingUsefulTwo` and we want to get the answer faster, by doing both *concurrently*? This is where async comes to help.

Conceptually, async is just like launch. It starts a separate coroutine which is a light-weight thread that works concurrently with all the other coroutines. The difference is that `launch` returns a Job and does not carry any resulting value, while `async` returns a Deferred — a light-weight non-blocking future that represents a promise to provide a result later. You can use `.await()` on a deferred value to get its eventual result, but `Deferred` is also a `Job`, so you can cancel it if needed.

```
import kotlinx.coroutines.*
import kotlin.system.*

fun main() = runBlocking<Unit> {
    val time = measureTimeMillis {
        val one = async { doSomethingUsefulOne() }
        val two = async { doSomethingUsefulTwo() }
        println("The answer is ${one.await() + two.await()}")
    }
    println("Completed in $time ms")
}

suspend fun doSomethingUsefulOne(): Int {
    delay(1000L) // pretend we are doing something useful here
    return 13
}

suspend fun doSomethingUsefulTwo(): Int {
    delay(1000L) // pretend we are doing something useful here, too
    return 29
}
```

You can get the full code here.

It produces something like this:

```
The answer is 42
Completed in 1017 ms
```

This is twice as fast, because the two coroutines execute concurrently. Note that concurrency with coroutines is always explicit.

Lazily started async

Optionally, async can be made lazy by setting its `start` parameter to CoroutineStart.LAZY. In this mode it only starts the coroutine when its result is required by await, or if its `Job` 's start function is invoked. Run the following example:

```
import kotlinx.coroutines.*
import kotlin.system.*

fun main() = runBlocking<Unit> {
    val time = measureTimeMillis {
        val one = async(start = CoroutineStart.LAZY) { doSomethingUsefulOne() }
        val two = async(start = CoroutineStart.LAZY) { doSomethingUsefulTwo() }
        // some computation
        one.start() // start the first one
        two.start() // start the second one
        println("The answer is ${one.await() + two.await()}")
    }
    println("Completed in $time ms")
}

suspend fun doSomethingUsefulOne(): Int {
    delay(1000L) // pretend we are doing something useful here
    return 13
}

suspend fun doSomethingUsefulTwo(): Int {
    delay(1000L) // pretend we are doing something useful here, too
    return 29
}
```

You can get the full code here.

It produces something like this:

```
The answer is 42
Completed in 1017 ms
```

So, here the two coroutines are defined but not executed as in the previous example, but the control is given to the programmer on when exactly to start the execution by calling start. We first start `one`, then start `two`, and then await for the individual coroutines to finish.

Note that if we just call await in `println` without first calling start on individual coroutines, this will lead to sequential behavior, since await starts the coroutine execution and waits for its finish, which is not the intended use-case for laziness. The use-case for `async(start = CoroutineStart.LAZY)` is a replacement for the standard lazy function in cases when computation of the value involves suspending functions.

Async-style functions

This programming style with async functions is provided here only for illustration, because it is a popular style in other programming languages. Using this style with Kotlin coroutines is **strongly discouraged** for the reasons explained below.

We can define async-style functions that invoke `doSomethingUsefulOne` and `doSomethingUsefulTwo` *asynchronously* using the async coroutine builder using a GlobalScope reference to opt-out of the structured concurrency. We name such functions with the "...Async" suffix to highlight the fact that they only start asynchronous computation and one needs to use the resulting deferred value to get the result.

GlobalScope is a delicate API that can backfire in non-trivial ways, one of which will be explained below, so you must explicitly opt-in into using `GlobalScope` with `@OptIn(DelicateCoroutinesApi::class)`.

```
// The result type of somethingUsefulOneAsync is Deferred<Int>
@OptIn(DelicateCoroutinesApi::class)
fun somethingUsefulOneAsync() = GlobalScope.async {
    doSomethingUsefulOne()
}

// The result type of somethingUsefulTwoAsync is Deferred<Int>
@OptIn(DelicateCoroutinesApi::class)
fun somethingUsefulTwoAsync() = GlobalScope.async {
    doSomethingUsefulTwo()
}
```

Note that these `xxxAsync` functions are **not** *suspending* functions. They can be used from anywhere. However, their use always implies asynchronous (here meaning *concurrent*) execution of their action with the invoking code.

The following example shows their use outside of coroutine:

```
import kotlinx.coroutines.*
import kotlin.system.*

// note that we don't have `runBlocking` to the right of `main` in this example
fun main() {
    val time = measureTimeMillis {
        // we can initiate async actions outside of a coroutine
        val one = somethingUsefulOneAsync()
        val two = somethingUsefulTwoAsync()
        // but waiting for a result must involve either suspending or blocking.
        // here we use `runBlocking { ... }` to block the main thread while waiting for the result
        runBlocking {
            println("The answer is ${one.await() + two.await()}")
        }
    }
    println("Completed in $time ms")
}

@OptIn(DelicateCoroutinesApi::class)
fun somethingUsefulOneAsync() = GlobalScope.async {
    doSomethingUsefulOne()
}

@OptIn(DelicateCoroutinesApi::class)
fun somethingUsefulTwoAsync() = GlobalScope.async {
    doSomethingUsefulTwo()
}

suspend fun doSomethingUsefulOne(): Int {
    delay(1000L) // pretend we are doing something useful here
    return 13
}

suspend fun doSomethingUsefulTwo(): Int {
    delay(1000L) // pretend we are doing something useful here, too
    return 29
}
```

You can get the full code here.

Consider what happens if between the `val one = somethingUsefulOneAsync()` line and `one.await()` expression there is some logic error in the code, and the program throws an exception, and the operation that was being performed by the program aborts. Normally, a global error-handler could catch this exception, log and report the error for developers, but the program could otherwise continue doing other operations. However, here we have `somethingUsefulOneAsync` still running in the background, even though the operation that initiated it was aborted. This problem does not happen with structured concurrency, as shown in the section below.

Structured concurrency with async

Let's refactor the Concurrent using async example into a function that runs `doSomethingUsefulOne` and `doSomethingUsefulTwo` concurrently and returns their combined results. Since async is a CoroutineScope extension, we'll use the coroutineScope function to provide the necessary scope:

```
suspend fun concurrentSum(): Int = coroutineScope {
    val one = async { doSomethingUsefulOne() }
    val two = async { doSomethingUsefulTwo() }
    one.await() + two.await()
}
```

This way, if something goes wrong inside the code of the `concurrentSum` function, and it throws an exception, all the coroutines that were launched in its scope will be cancelled.

```
import kotlinx.coroutines.*
import kotlin.system.*

fun main() = runBlocking<Unit> {
    val time = measureTimeMillis {
        println("The answer is ${concurrentSum()}")
    }
    println("Completed in $time ms")
}

suspend fun concurrentSum(): Int = coroutineScope {
    val one = async { doSomethingUsefulOne() }
    val two = async { doSomethingUsefulTwo() }
    one.await() + two.await()
}

suspend fun doSomethingUsefulOne(): Int {
    delay(1000L) // pretend we are doing something useful here
    return 13
}

suspend fun doSomethingUsefulTwo(): Int {
    delay(1000L) // pretend we are doing something useful here, too
    return 29
}
```

You can get the full code here.

We still have concurrent execution of both operations, as evident from the output of the above `main` function:

```
The answer is 42
Completed in 1017 ms
```

Cancellation is always propagated through coroutines hierarchy:

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    try {
        failedConcurrentSum()
    } catch(e: ArithmeticException) {
        println("Computation failed with ArithmeticException")
    }
}

suspend fun failedConcurrentSum(): Int = coroutineScope {
    val one = async<Int> {
        try {
            delay(Long.MAX_VALUE) // Emulates very long computation
            42
        } finally {
            println("First child was cancelled")
        }
    }
    val two = async<Int> {
        println("Second child throws an exception")
        throw ArithmeticException()
    }
    one.await() + two.await()
}
```

You can get the full code here.

Note how both the first `async` and the awaiting parent are cancelled on failure of one of the children (namely, `two`):

```
Second child throws an exception
First child was cancelled
Computation failed with ArithmeticException
```

Coroutine context and dispatchers

Coroutines always execute in some context represented by a value of the CoroutineContext type, defined in the Kotlin standard library.

The coroutine context is a set of various elements. The main elements are the Job of the coroutine, which we've seen before, and its dispatcher, which is covered in this section.

Dispatchers and threads

The coroutine context includes a *coroutine dispatcher* (see CoroutineDispatcher) that determines what thread or threads the corresponding coroutine uses for its execution. The coroutine dispatcher can confine coroutine execution to a specific thread, dispatch it to a thread pool, or let it run unconfined.

All coroutine builders like launch and async accept an optional CoroutineContext parameter that can be used to explicitly specify the dispatcher for the new coroutine and other context elements.

Try the following example:

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    launch { // context of the parent, main runBlocking coroutine
        println("main runBlocking      : I'm working in thread ${Thread.currentThread().name}")
    }
    launch(Dispatchers.Unconfined) { // not confined -- will work with main thread
        println("Unconfined            : I'm working in thread ${Thread.currentThread().name}")
    }
    launch(Dispatchers.Default) { // will get dispatched to DefaultDispatcher
        println("Default               : I'm working in thread ${Thread.currentThread().name}")
    }
    launch(newSingleThreadContext("MyOwnThread")) { // will get its own new thread
        println("newSingleThreadContext: I'm working in thread ${Thread.currentThread().name}")
    }
}
```

You can get the full code here.

It produces the following output (maybe in different order):

```
Unconfined            : I'm working in thread main
Default               : I'm working in thread DefaultDispatcher-worker-1
newSingleThreadContext: I'm working in thread MyOwnThread
main runBlocking      : I'm working in thread main
```

When `launch { ... }` is used without parameters, it inherits the context (and thus dispatcher) from the CoroutineScope it is being launched from. In this case, it inherits the context of the main `runBlocking` coroutine which runs in the `main` thread.

Dispatchers.Unconfined is a special dispatcher that also appears to run in the `main` thread, but it is, in fact, a different mechanism that is explained later.

The default dispatcher is used when no other dispatcher is explicitly specified in the scope. It is represented by Dispatchers.Default and uses a shared background pool of threads.

newSingleThreadContext creates a thread for the coroutine to run. A dedicated thread is a very expensive resource. In a real application it must be either released, when no longer needed, using the close function, or stored in a top-level variable and reused throughout the application.

Unconfined vs confined dispatcher

The Dispatchers.Unconfined coroutine dispatcher starts a coroutine in the caller thread, but only until the first suspension point. After suspension it resumes the coroutine in the thread that is fully determined by the suspending function that was invoked. The unconfined dispatcher is appropriate for coroutines which neither consume CPU time nor update any shared data (like UI) confined to a specific thread.

On the other side, the dispatcher is inherited from the outer CoroutineScope by default. The default dispatcher for the runBlocking coroutine, in particular, is confined to the invoker thread, so inheriting it has the effect of confining execution to this thread with predictable FIFO scheduling.

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    launch(Dispatchers.Unconfined) { // not confined -- will work with main thread
        println("Unconfined      : I'm working in thread ${Thread.currentThread().name}")
        delay(500)
        println("Unconfined      : After delay in thread ${Thread.currentThread().name}")
    }
    launch { // context of the parent, main runBlocking coroutine
        println("main runBlocking: I'm working in thread ${Thread.currentThread().name}")
        delay(1000)
        println("main runBlocking: After delay in thread ${Thread.currentThread().name}")
    }
}
```

You can get the full code here.

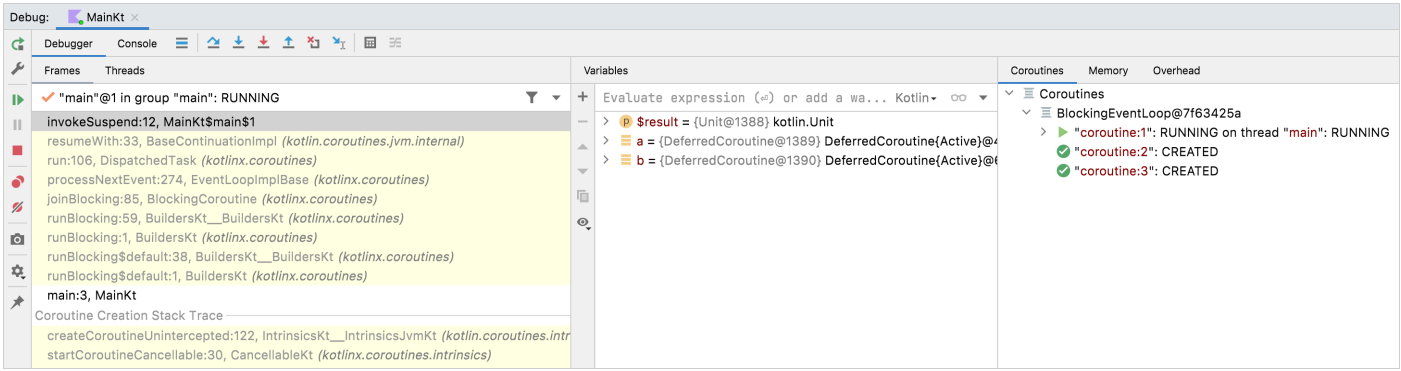
Produces the output:

```
Unconfined      : I'm working in thread main
main runBlocking: I'm working in thread main
Unconfined      : After delay in thread kotlinx.coroutines.DefaultExecutor
main runBlocking: After delay in thread main
```

So, the coroutine with the context inherited from `runBlocking {...}` continues to execute in the `main` thread, while the unconfined one resumes in the default executor thread that the delay function is using.

The unconfined dispatcher is an advanced mechanism that can be helpful in certain corner cases where dispatching of a coroutine for its execution later is not needed or produces undesirable side-effects, because some operation in a coroutine must be performed right away. The unconfined dispatcher should not be used in general code.

Debugging coroutines and threads



Coroutines can suspend on one thread and resume on another thread. Even with a single-threaded dispatcher it might be hard to figure out what the coroutine was doing, where, and when if you don't have special tooling.

Debugging with IDEA

The Coroutine Debugger of the Kotlin plugin simplifies debugging coroutines in IntelliJ IDEA.

Debugging works for versions 1.3.8 or later of `kotlinx-coroutines-core`.

The **Debug** tool window contains the **Coroutines** tab. In this tab, you can find information about both currently running and suspended coroutines. The coroutines are grouped by the dispatcher they are running on.

Debugging coroutines

With the coroutine debugger, you can:

- Check the state of each coroutine.
- See the values of local and captured variables for both running and suspended coroutines.
- See a full coroutine creation stack, as well as a call stack inside the coroutine. The stack includes all frames with variable values, even those that would be lost during standard debugging.
- Get a full report that contains the state of each coroutine and its stack. To obtain it, right-click inside the **Coroutines** tab, and then click **Get Coroutines Dump**.

To start coroutine debugging, you just need to set breakpoints and run the application in debug mode.

Learn more about coroutines debugging in the tutorial.

Debugging using logging

Another approach to debugging applications with threads without Coroutine Debugger is to print the thread name in the log file on each log statement. This feature is universally supported by logging frameworks. When using coroutines, the thread name alone does not give much of a context, so `kotlinx.coroutines` includes debugging facilities to make it easier.

Run the following code with `-Dkotlinx.coroutines.debug` JVM option:

```
import kotlinx.coroutines.*

fun log(msg: String) = println("[${Thread.currentThread().name}] $msg")

fun main() = runBlocking<Unit> {
    val a = async {
        log("I'm computing a piece of the answer")
        6
    }
    val b = async {
        log("I'm computing another piece of the answer")
        7
    }
    log("The answer is ${a.await() * b.await()}")
}
```

You can get the full code here.

There are three coroutines. The main coroutine (#1) inside `runBlocking` and two coroutines computing the deferred values `a` (#2) and `b` (#3). They are all executing in the context of `runBlocking` and are confined to the main thread. The output of this code is:

```
[main @coroutine#2] I'm computing a piece of the answer
[main @coroutine#3] I'm computing another piece of the answer
[main @coroutine#1] The answer is 42
```

The `log` function prints the name of the thread in square brackets, and you can see that it is the `main` thread with the identifier of the currently executing coroutine appended to it. This identifier is consecutively assigned to all created coroutines when the debugging mode is on.

> Debugging mode is also turned on when JVM is run with `-ea` option. You can read more about debugging facilities in the documentation of the DEBUG_PROPERTY_NAME property.

Jumping between threads

Run the following code with the `-Dkotlinx.coroutines.debug` JVM option (see debug):

```
import kotlinx.coroutines.*

fun log(msg: String) = println("[${Thread.currentThread().name}] $msg")

fun main() {
    newSingleThreadContext("Ctx1").use { ctx1 →
        newSingleThreadContext("Ctx2").use { ctx2 →
            runBlocking(ctx1) {
                log("Started in ctx1")
                withContext(ctx2) {
                    log("Working in ctx2")
                }
                log("Back to ctx1")
            }
        }
    }
}
```

> You can get the full code here.

The example above demonstrates new techniques in coroutine usage.

The first technique shows how to use runBlocking with a specified context.
The second technique involves calling withContext, which may suspend the current coroutine and switch to a new context—provided the new context differs from the existing one. Specifically, if you specify a different CoroutineDispatcher, extra dispatches are required: the block is scheduled on the new dispatcher, and once it finishes, execution returns to the original dispatcher.

As a result, the output of the above code is:

```
[Ctx1 @coroutine#1] Started in ctx1
[Ctx2 @coroutine#1] Working in ctx2
[Ctx1 @coroutine#1] Back to ctx1
```

The example above uses the `use` function from the Kotlin standard library to properly release thread resources created by newSingleThreadContext when they're no longer needed.

Job in the context

The coroutine's Job is part of its context, and can be retrieved from it using the `coroutineContext[Job]` expression:

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    println("My job is ${coroutineContext[Job]}")
}
```

You can get the full code here.

In debug mode, it outputs something like this:

```
My job is "coroutine#1":BlockingCoroutine{Active}@6d311334
```

Note that isActive in CoroutineScope is just a convenient shortcut for `coroutineContext[Job]?.isActive == true`.

Children of a coroutine

When a coroutine is launched in the CoroutineScope of another coroutine, it inherits its context via CoroutineScope.coroutineContext and the Job of the new coroutine becomes a *child* of the parent coroutine's job. When the parent coroutine is cancelled, all its children are recursively cancelled, too.

However, this parent-child relation can be explicitly overridden in one of two ways:

1. When a different scope is explicitly specified when launching a coroutine (for example, `GlobalScope.launch`), it does not inherit a `Job` from the parent scope.
2. When a different `Job` object is passed as the context for the new coroutine (as shown in the example below), it overrides the `Job` of the parent scope.

In both cases, the launched coroutine is not tied to the scope it was launched from and operates independently.

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    // launch a coroutine to process some kind of incoming request
    val request = launch {
        // it spawns two other jobs
        launch(Job()) {
            println("job1: I run in my own Job and execute independently!")
            delay(1000)
            println("job1: I am not affected by cancellation of the request")
        }
        // and the other inherits the parent context
        launch {
            delay(100)
            println("job2: I am a child of the request coroutine")
            delay(1000)
            println("job2: I will not execute this line if my parent request is cancelled")
        }
    }
    delay(500)
    request.cancel() // cancel processing of the request
    println("main: Who has survived request cancellation?")
    delay(1000) // delay the main thread for a second to see what happens
}
```

You can get the full code here.

The output of this code is:

```
job1: I run in my own Job and execute independently!
job2: I am a child of the request coroutine
main: Who has survived request cancellation?
job1: I am not affected by cancellation of the request
```

Parental responsibilities

A parent coroutine always waits for the completion of all its children. A parent does not have to explicitly track all the children it launches, and it does not have to use Job.join to wait for them at the end:

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    // launch a coroutine to process some kind of incoming request
    val request = launch {
        repeat(3) { i -> // launch a few children jobs
            launch  {
                delay((i + 1) * 200L) // variable delay 200ms, 400ms, 600ms
                println("Coroutine $i is done")
            }
        }
        println("request: I'm done and I don't explicitly join my children that are still active")
    }
    request.join() // wait for completion of the request, including all its children
    println("Now processing of the request is complete")
}
```

You can get the full code here.

The result is going to be:

```
request: I'm done and I don't explicitly join my children that are still active
Coroutine 0 is done
Coroutine 1 is done
Coroutine 2 is done
Now processing of the request is complete
```

Naming coroutines for debugging

Automatically assigned ids are good when coroutines log often and you just need to correlate log records coming from the same coroutine. However, when a coroutine is tied to the processing of a specific request or doing some specific background task, it is better to name it explicitly for debugging purposes. The CoroutineName context element serves the same purpose as the thread name. It is included in the thread name that is executing this coroutine when the debugging mode is turned on.

The following example demonstrates this concept:

```
import kotlinx.coroutines.*

fun log(msg: String) = println("[${Thread.currentThread().name}] $msg")

fun main() = runBlocking(CoroutineName("main")) {
    log("Started main coroutine")
    // run two background value computations
    val v1 = async(CoroutineName("v1coroutine")) {
        delay(500)
        log("Computing v1")
        6
    }
    val v2 = async(CoroutineName("v2coroutine")) {
        delay(1000)
        log("Computing v2")
        7
    }
    log("The answer for v1 * v2 = ${v1.await() * v2.await()}")
}
```

You can get the full code here.

The output it produces with `-Dkotlinx.coroutines.debug` JVM option is similar to:

```
[main @main#1] Started main coroutine
[main @v1coroutine#2] Computing v1
[main @v2coroutine#3] Computing v2
[main @main#1] The answer for v1 * v2 = 42
```

Combining context elements

Sometimes we need to define multiple elements for a coroutine context. We can use the `+` operator for that. For example, we can launch a coroutine with an explicitly specified dispatcher and an explicitly specified name at the same time:

```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    launch(Dispatchers.Default + CoroutineName("test")) {
        println("I'm working in thread ${Thread.currentThread().name}")
    }
}
```

You can get the full code here.

The output of this code with the `-Dkotlinx.coroutines.debug` JVM option is:

```
I'm working in thread DefaultDispatcher-worker-1 @test#2
```

Coroutine scope

Let us put our knowledge about contexts, children, and jobs together. Assume that our application has an object with a lifecycle, but that object is not a coroutine. For example, we are writing an Android application, and launching various coroutines in the context of an Android activity to perform asynchronous operations to fetch and update data, do animations, etc. These coroutines must be cancelled when the activity is destroyed to avoid memory leaks. We, of course, can manipulate contexts and jobs manually to tie the lifecycles of the activity and its coroutines, but `kotlinx.coroutines` provides an abstraction encapsulating that: CoroutineScope. You should be already familiar with the coroutine scope as all coroutine builders are declared as extensions on it.

We manage the lifecycles of our coroutines by creating an instance of CoroutineScope tied to the lifecycle of our activity. A `CoroutineScope` instance can be created by the CoroutineScope() or MainScope() factory functions. The former creates a general-purpose scope, while the latter creates a scope for UI applications and uses Dispatchers.Main as the default dispatcher:

```
class Activity {
    private val mainScope = MainScope()

    fun destroy() {
        mainScope.cancel()
    }
    // to be continued ...
```

Now, we can launch coroutines in the scope of this `Activity` using the defined `mainScope`. For the demo, we launch ten coroutines that delay for a different time:

```
// class Activity continues
    fun doSomething() {
        // launch ten coroutines for a demo, each working for a different time
        repeat(10) { i ->
            mainScope.launch {
                delay((i + 1) * 200L) // variable delay 200ms, 400ms, ... etc
                println("Coroutine $i is done")
            }
        }
    }
} // class Activity ends
```

In our main function we create the activity, call our test `doSomething` function, and destroy the activity after 500ms. This cancels all the coroutines that were launched from `doSomething`. We can see that because after the destruction of the activity, no more messages are printed, even if we wait a little longer.

```
import kotlinx.coroutines.*

class Activity {
    private val mainScope = CoroutineScope(Dispatchers.Default) // use Default for test purposes

    fun destroy() {
        mainScope.cancel()
    }

    fun doSomething() {
        // launch ten coroutines for a demo, each working for a different time
        repeat(10) { i ->
            mainScope.launch {
                delay((i + 1) * 200L) // variable delay 200ms, 400ms, ... etc
                println("Coroutine $i is done")
            }
        }
    }
} // class Activity ends

fun main() = runBlocking<Unit> {
    val activity = Activity()
    activity.doSomething() // run test function
    println("Launched coroutines")
    delay(500L) // delay for half a second
    println("Destroying activity!")
    activity.destroy() // cancels all coroutines
    delay(1000) // visually confirm that they don't work
}
```

You can get the full code here.

The output of this example is:

```
Launched coroutines
Coroutine 0 is done
Coroutine 1 is done
Destroying activity!
```

As you can see, only the first two coroutines print a message and the others are cancelled by a single invocation of `mainScope.cancel()` in `Activity.destroy()`.

Note that Android has first-party support for coroutine scope in all entities with the lifecycle. See the corresponding documentation.

Thread-local data

Sometimes it is convenient to be able to pass some thread-local data to or between coroutines. However, since they are not bound to any particular thread, this will likely lead to boilerplate if done manually.

For `ThreadLocal`, the asContextElement extension function is here for the rescue. It creates an additional context element which keeps the value of the given `ThreadLocal` and restores it every time the coroutine switches its context.

It is easy to demonstrate it in action:

```
import kotlinx.coroutines.*

val threadLocal = ThreadLocal<String?>() // declare thread-local variable

fun main() = runBlocking<Unit> {
    threadLocal.set("main")
    println("Pre-main, current thread: ${Thread.currentThread()}, thread local value:
'${threadLocal.get()}'")
    val job = launch(Dispatchers.Default + threadLocal.asContextElement(value = "launch")) {
        println("Launch start, current thread: ${Thread.currentThread()}, thread local value:
'${threadLocal.get()}'")
        yield()
        println("After yield, current thread: ${Thread.currentThread()}, thread local value:
'${threadLocal.get()}'")
    }
    job.join()
    println("Post-main, current thread: ${Thread.currentThread()}, thread local value:
'${threadLocal.get()}'")
}
```

You can get the full code here.

In this example, we launch a new coroutine in a background thread pool using Dispatchers.Default, so it works on different threads from the thread pool, but it still has the value of the thread local variable that we specified using `threadLocal.asContextElement(value = "launch")`, no matter which thread the coroutine is executed on. Thus, the output (with debug) is:

```
Pre-main, current thread: Thread[main @coroutine#1,5,main], thread local value: 'main'
Launch start, current thread: Thread[DefaultDispatcher-worker-1 @coroutine#2,5,main], thread local
value: 'launch'
After yield, current thread: Thread[DefaultDispatcher-worker-2 @coroutine#2,5,main], thread local
value: 'launch'
Post-main, current thread: Thread[main @coroutine#1,5,main], thread local value: 'main'
```

It's easy to forget to set the corresponding context element. The thread-local variable accessed from the coroutine may then have an unexpected value if the thread running the coroutine is different. To avoid such situations, it is recommended to use the ensurePresent method and fail-fast on improper usages.

`ThreadLocal` has first-class support and can be used with any primitive `kotlinx.coroutines` provides. It has one key limitation, though: when a thread-local is mutated, a new value is not propagated to the coroutine caller (because a context element cannot track all `ThreadLocal` object accesses), and the updated value is lost on the

next suspension. Use withContext to update the value of the thread-local in a coroutine, see asContextElement for more details.

Alternatively, a value can be stored in a mutable box like `class Counter(var i: Int)`, which is, in turn, stored in a thread-local variable. However, in this case, you are fully responsible to synchronize potentially concurrent modifications to the variable in this mutable box.

For advanced usage, for example, for integration with logging MDC, transactional contexts or any other libraries that internally use thread-locals for passing data, see the documentation of the ThreadContextElement interface that should be implemented.

Channels

Deferred values provide a convenient way to transfer a single value between coroutines. Channels provide a way to transfer a stream of values.

Channel basics

A Channel is conceptually very similar to `BlockingQueue`. One key difference is that instead of a blocking `put` operation it has a suspending send, and instead of a blocking `take` operation it has a suspending receive.

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking {
    val channel = Channel<Int>()
    launch {
        // this might be heavy CPU-consuming computation or async logic,
        // we'll just send five squares
        for (x in 1..5) channel.send(x * x)
    }
    // here we print five received integers:
    repeat(5) { println(channel.receive()) }
    println("Done!")
}
```

You can get the full code here.

The output of this code is:

```
1
4
9
16
25
Done!
```

Closing and iteration over channels

Unlike a queue, a channel can be closed to indicate that no more elements are coming. On the receiver side it is convenient to use a regular `for` loop to receive elements from the channel.

Conceptually, a close is like sending a special close token to the channel. The iteration stops as soon as this close token is received, so there is a guarantee that all previously sent elements before the close are received:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking {
    val channel = Channel<Int>()
    launch {
        for (x in 1..5) channel.send(x * x)
        channel.close() // we're done sending
    }
    // here we print received values using `for` loop (until the channel is closed)
    for (y in channel) println(y)
    println("Done!")
}
```

You can get the full code here.

Building channel producers

The pattern where a coroutine is producing a sequence of elements is quite common. This is a part of *producer-consumer* pattern that is often found in concurrent code. You could abstract such a producer into a function that takes channel as its parameter, but this goes contrary to common sense that results must be returned from functions.

There is a convenient coroutine builder named produce that makes it easy to do it right on producer side, and an extension function consumeEach, that replaces a `for` loop on the consumer side:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun CoroutineScope.produceSquares(): ReceiveChannel<Int> = produce {
    for (x in 1..5) send(x * x)
}

fun main() = runBlocking {
    val squares = produceSquares()
    squares.consumeEach { println(it) }
    println("Done!")
}
```

You can get the full code here.

Pipelines

A pipeline is a pattern where one coroutine is producing, possibly infinite, stream of values:

```
fun CoroutineScope.produceNumbers() = produce<Int> {
    var x = 1
    while (true) send(x++) // infinite stream of integers starting from 1
}
```

And another coroutine or coroutines are consuming that stream, doing some processing, and producing some other results. In the example below, the numbers are just squared:

```
fun CoroutineScope.square(numbers: ReceiveChannel<Int>): ReceiveChannel<Int> = produce {
    for (x in numbers) send(x * x)
}
```

The main code starts and connects the whole pipeline:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking {
    val numbers = produceNumbers() // produces integers from 1 and on
    val squares = square(numbers) // squares integers
    repeat(5) {
        println(squares.receive()) // print first five
    }
    println("Done!") // we are done
    coroutineContext.cancelChildren() // cancel children coroutines
}

fun CoroutineScope.produceNumbers() = produce<Int> {
    var x = 1
    while (true) send(x++) // infinite stream of integers starting from 1
}

fun CoroutineScope.square(numbers: ReceiveChannel<Int>): ReceiveChannel<Int> = produce {
    for (x in numbers) send(x * x)
}
```

You can get the full code here.

All functions that create coroutines are defined as extensions on CoroutineScope, so that we can rely on structured concurrency to make sure that we don't have lingering global coroutines in our application.

Prime numbers with pipeline

Let's take pipelines to the extreme with an example that generates prime numbers using a pipeline of coroutines. We start with an infinite sequence of numbers.

```
fun CoroutineScope.numbersFrom(start: Int) = produce<Int> {
    var x = start
    while (true) send(x++) // infinite stream of integers from start
}
```

The following pipeline stage filters an incoming stream of numbers, removing all the numbers that are divisible by the given prime number:

```
fun CoroutineScope.filter(numbers: ReceiveChannel<Int>, prime: Int) = produce<Int> {
    for (x in numbers) if (x % prime != 0) send(x)
}
```

Now we build our pipeline by starting a stream of numbers from 2, taking a prime number from the current channel, and launching new pipeline stage for each prime number found:

```
numbersFrom(2) → filter(2) → filter(3) → filter(5) → filter(7) ...
```

The following example prints the first ten prime numbers, running the whole pipeline in the context of the main thread. Since all the coroutines are launched in the scope of the main runBlocking coroutine we don't have to keep an explicit list of all the coroutines we have started. We use cancelChildren extension function to cancel all the children coroutines after we have printed the first ten prime numbers.

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking {
    var cur = numbersFrom(2)
    repeat(10) {
        val prime = cur.receive()
        println(prime)
        cur = filter(cur, prime)
    }
    coroutineContext.cancelChildren() // cancel all children to let main finish
}

fun CoroutineScope.numbersFrom(start: Int) = produce<Int> {
    var x = start
    while (true) send(x++) // infinite stream of integers from start
}

fun CoroutineScope.filter(numbers: ReceiveChannel<Int>, prime: Int) = produce<Int> {
    for (x in numbers) if (x % prime ≠ 0) send(x)
}
```

You can get the full code here.

The output of this code is:

```
2
3
5
7
11
13
17
19
23
29
```

Note that you can build the same pipeline using `iterator` coroutine builder from the standard library. Replace `produce` with `iterator`, `send` with `yield`, `receive` with `next`, `ReceiveChannel` with `Iterator`, and get rid of the coroutine scope. You will not need `runBlocking` either. However, the benefit of a pipeline that uses channels as shown above is that it can actually use multiple CPU cores if you run it in Dispatchers.Default context.

Anyway, this is an extremely impractical way to find prime numbers. In practice, pipelines do involve some other suspending invocations (like asynchronous calls to remote services) and these pipelines cannot be built using `sequence` / `iterator`, because they do not allow arbitrary suspension, unlike `produce`, which is fully asynchronous.

Fan-out

Multiple coroutines may receive from the same channel, distributing work between themselves. Let us start with a producer coroutine that is periodically producing integers (ten numbers per second):

```
fun CoroutineScope.produceNumbers() = produce<Int> {
    var x = 1 // start from 1
    while (true) {
        send(x++) // produce next
        delay(100) // wait 0.1s
    }
}
```

Then we can have several processor coroutines. In this example, they just print their id and received number:

```
fun CoroutineScope.launchProcessor(id: Int, channel: ReceiveChannel<Int>) = launch {
    for (msg in channel) {
        println("Processor #$id received $msg")
    }
}
```

Now let us launch five processors and let them work for almost a second. See what happens:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking<Unit> {
    val producer = produceNumbers()
    repeat(5) { launchProcessor(it, producer) }
    delay(950)
    producer.cancel() // cancel producer coroutine and thus kill them all
}

fun CoroutineScope.produceNumbers() = produce<Int> {
    var x = 1 // start from 1
    while (true) {
        send(x++) // produce next
        delay(100) // wait 0.1s
    }
}

fun CoroutineScope.launchProcessor(id: Int, channel: ReceiveChannel<Int>) = launch {
    for (msg in channel) {
        println("Processor #$id received $msg")
    }
}
```

You can get the full code here.

The output will be similar to the following one, albeit the processor ids that receive each specific integer may be different:

```
Processor #2 received 1
Processor #4 received 2
Processor #0 received 3
Processor #1 received 4
Processor #3 received 5
Processor #2 received 6
Processor #4 received 7
Processor #0 received 8
Processor #1 received 9
Processor #3 received 10
```

Note that cancelling a producer coroutine closes its channel, thus eventually terminating iteration over the channel that processor coroutines are doing.

Also, pay attention to how we explicitly iterate over channel with `for` loop to perform fan-out in `launchProcessor` code. Unlike `consumeEach`, this `for` loop pattern is perfectly safe to use from multiple coroutines. If one of the processor coroutines fails, then others would still be processing the channel, while a processor that is written via `consumeEach` always consumes (cancels) the underlying channel on its normal or abnormal completion.

Fan-in

Multiple coroutines may send to the same channel. For example, let us have a channel of strings, and a suspending function that repeatedly sends a specified string to this channel with a specified delay:

```
suspend fun sendString(channel: SendChannel<String>, s: String, time: Long) {
    while (true) {
        delay(time)
        channel.send(s)
    }
}
```

Now, let us see what happens if we launch a couple of coroutines sending strings (in this example we launch them in the context of the main thread as main coroutine's children):

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking {
    val channel = Channel<String>()
    launch { sendString(channel, "foo", 200L) }
    launch { sendString(channel, "BAR!", 500L) }
    repeat(6) { // receive first six
        println(channel.receive())
    }
    coroutineContext.cancelChildren() // cancel all children to let main finish
}

suspend fun sendString(channel: SendChannel<String>, s: String, time: Long) {
    while (true) {
        delay(time)
        channel.send(s)
    }
}
```

You can get the full code here.

The output is:

```
foo
foo
BAR!
foo
foo
BAR!
```

Buffered channels

The channels shown so far had no buffer. Unbuffered channels transfer elements when sender and receiver meet each other (aka rendezvous). If send is invoked first, then it is suspended until receive is invoked, if receive is invoked first, it is suspended until send is invoked.

Both Channel() factory function and produce builder take an optional `capacity` parameter to specify *buffer size*. Buffer allows senders to send multiple elements before suspending, similar to the `BlockingQueue` with a specified capacity, which blocks when buffer is full.

Take a look at the behavior of the following code:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking<Unit> {
    val channel = Channel<Int>(4) // create buffered channel
    val sender = launch { // launch sender coroutine
        repeat(10) {
            println("Sending $it") // print before sending each element
            channel.send(it) // will suspend when buffer is full
        }
    }
    // don't receive anything... just wait....
    delay(1000)
    sender.cancel() // cancel sender coroutine
}
```

You can get the full code here.

It prints "sending" *five* times using a buffered channel with capacity of *four*:

```
Sending 0
Sending 1
Sending 2
Sending 3
Sending 4
```

The first four elements are added to the buffer and the sender suspends when trying to send the fifth one.

Channels are fair

Send and receive operations to channels are *fair* with respect to the order of their invocation from multiple coroutines. They are served in first-in first-out order, e.g. the first coroutine to invoke `receive` gets the element.

In the following example two coroutines "ping" and "pong" are receiving the "ball" object from the shared "table" channel.

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

data class Ball(var hits: Int)

fun main() = runBlocking {
    val table = Channel<Ball>() // a shared table
    launch { player("ping", table) }
    launch { player("pong", table) }
    table.send(Ball(0)) // serve the ball
    delay(1000) // delay 1 second
    coroutineContext.cancelChildren() // game over, cancel them
}

suspend fun player(name: String, table: Channel<Ball>) {
    for (ball in table) { // receive the ball in a loop
        ball.hits++
        println("$name $ball")
        delay(300) // wait a bit
        table.send(ball) // send the ball back
    }
}
```

You can get the full code here.

The "ping" coroutine is started first, so it is the first one to receive the ball. Even though "ping" coroutine immediately starts receiving the ball again after sending it back to the table, the ball gets received by the "pong" coroutine, because it was already waiting for it:

```
ping Ball(hits=1)
pong Ball(hits=2)
ping Ball(hits=3)
pong Ball(hits=4)
```

Note that sometimes channels may produce executions that look unfair due to the nature of the executor that is being used. See this issue for details.

Ticker channels

Ticker channel is a special rendezvous channel that produces `Unit` every time given delay passes since last consumption from this channel. Though it may seem to be useless standalone, it is a useful building block to create complex time-based produce pipelines and operators that do windowing and other time-dependent processing. Ticker channel can be used in select to perform "on tick" action.

To create such channel use a factory method ticker. To indicate that no further elements are needed use ReceiveChannel.cancel method on it.

Now let's see how it works in practice:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*

fun main() = runBlocking<Unit> {
    val tickerChannel = ticker(delayMillis = 200, initialDelayMillis = 0) // create a ticker channel
    var nextElement = withTimeoutOrNull(1) { tickerChannel.receive() }
    println("Initial element is available immediately: $nextElement") // no initial delay

    nextElement = withTimeoutOrNull(100) { tickerChannel.receive() } // all subsequent elements have
200ms delay
    println("Next element is not ready in 100 ms: $nextElement")

    nextElement = withTimeoutOrNull(120) { tickerChannel.receive() }
    println("Next element is ready in 200 ms: $nextElement")

    // Emulate large consumption delays
    println("Consumer pauses for 300ms")
    delay(300)
    // Next element is available immediately
    nextElement = withTimeoutOrNull(1) { tickerChannel.receive() }
    println("Next element is available immediately after large consumer delay: $nextElement")
    // Note that the pause between `receive` calls is taken into account and next element arrives
faster
    nextElement = withTimeoutOrNull(120) { tickerChannel.receive() }
    println("Next element is ready in 100ms after consumer pause in 300ms: $nextElement")

    tickerChannel.cancel() // indicate that no more elements are needed
}
```

You can get the full code here.

It prints following lines:

```
Initial element is available immediately: kotlin.Unit
Next element is not ready in 100 ms: null
Next element is ready in 200 ms: kotlin.Unit
Consumer pauses for 300ms
Next element is available immediately after large consumer delay: kotlin.Unit
Next element is ready in 100ms after consumer pause in 300ms: kotlin.Unit
```

Note that ticker is aware of possible consumer pauses and, by default, adjusts next produced element delay if a pause occurs, trying to maintain a fixed rate of produced elements.

Optionally, a `mode` parameter equal to TickerMode.FIXED_DELAY can be specified to maintain a fixed delay between elements.

Coroutine exceptions handling

This section covers exception handling and cancellation on exceptions. We already know that a cancelled coroutine throws CancellationException in suspension points and that it is ignored by the coroutines' machinery. Here we look at what happens if an exception is thrown during cancellation or multiple children of the same coroutine throw an exception.

Exception propagation

Coroutine builders come in two flavors: propagating exceptions automatically (launch) or exposing them to users (async and produce). When these builders are used to create a *root* coroutine, that is not a *child* of another coroutine, the former builders treat exceptions as **uncaught** exceptions, similar to Java's `Thread.uncaughtExceptionHandler`, while the latter are relying on the user to consume the final exception, for example via await or receive (produce and receive are covered in Channels section).

It can be demonstrated by a simple example that creates root coroutines using the GlobalScope:

> GlobalScope is a delicate API that can backfire in non-trivial ways. Creating a root coroutine for the whole application is one of the rare legitimate uses for `GlobalScope`, so you must explicitly opt-in into using `GlobalScope` with `@OptIn(DelicateCoroutinesApi::class)`.

```
import kotlinx.coroutines.*

@OptIn(DelicateCoroutinesApi::class)
fun main() = runBlocking {
    val job = GlobalScope.launch { // root coroutine with launch
        println("Throwing exception from launch")
        throw IndexOutOfBoundsException() // Will be printed to the console by
Thread.defaultUncaughtExceptionHandler
    }
    job.join()
    println("Joined failed job")
    val deferred = GlobalScope.async { // root coroutine with async
        println("Throwing exception from async")
        throw ArithmeticException() // Nothing is printed, relying on user to call await
    }
    try {
        deferred.await()
        println("Unreached")
    } catch (e: ArithmeticException) {
        println("Caught ArithmeticException")
    }
}
```

> You can get the full code here.

The output of this code is (with debug):

```
Throwing exception from launch
Exception in thread "DefaultDispatcher-worker-1 @coroutine#2" java.lang.IndexOutOfBoundsException
Joined failed job
Throwing exception from async
Caught ArithmeticException
```

CoroutineExceptionHandler

It is possible to customize the default behavior of printing **uncaught** exceptions to the console. CoroutineExceptionHandler context element on a *root* coroutine can be used as a generic `catch` block for this root coroutine and all its children where custom exception handling may take place. It is similar to `Thread.uncaughtExceptionHandler`. You cannot recover from the exception in the

`CoroutineExceptionHandler`. The coroutine had already completed with the corresponding exception when the handler is called. Normally, the handler is used to log the exception, show some kind of error message, terminate, and/or restart the application.

`CoroutineExceptionHandler` is invoked only on **uncaught** exceptions — exceptions that were not handled in any other way. In particular, all *children* coroutines (coroutines created in the context of another Job) delegate handling of their exceptions to their parent coroutine, which also delegates to the parent, and so on until the root, so the `CoroutineExceptionHandler` installed in their context is never used. In addition to that, async builder always catches all exceptions and represents them in the resulting Deferred object, so its `CoroutineExceptionHandler` has no effect either.

Coroutines running in supervision scope do not propagate exceptions to their parent and are excluded from this rule. A further Supervision section of this document gives more details.

```
import kotlinx.coroutines.*

@OptIn(DelicateCoroutinesApi::class)
fun main() = runBlocking {
    val handler = CoroutineExceptionHandler { _, exception →
        println("CoroutineExceptionHandler got $exception")
    }
    val job = GlobalScope.launch(handler) { // root coroutine, running in GlobalScope
        throw AssertionError()
    }
    val deferred = GlobalScope.async(handler) { // also root, but async instead of launch
        throw ArithmeticException() // Nothing will be printed, relying on user to call
deferred.await()
    }
    joinAll(job, deferred)
}
```

You can get the full code here.

The output of this code is:

```
CoroutineExceptionHandler got java.lang.AssertionError
```

Cancellation and exceptions

Cancellation is closely related to exceptions. Coroutines internally use `CancellationException` for cancellation, these exceptions are ignored by all handlers, so they should be used only as the source of additional debug information, which can be obtained by `catch` block. When a coroutine is cancelled using Job.cancel, it terminates, but it does not cancel its parent.

```
import kotlinx.coroutines.*

fun main() = runBlocking {
    val job = launch {
        val child = launch {
            try {
                delay(Long.MAX_VALUE)
            } finally {
                println("Child is cancelled")
            }
        }
        yield()
        println("Cancelling child")
        child.cancel()
        child.join()
        yield()
        println("Parent is not cancelled")
    }
    job.join()
}
```

You can get the full code here.

The output of this code is:

```
Cancelling child
Child is cancelled
Parent is not cancelled
```

If a coroutine encounters an exception other than `CancellationException`, it cancels its parent with that exception. This behaviour cannot be overridden and is used to provide stable coroutines hierarchies for structured concurrency. CoroutineExceptionHandler implementation is not used for child coroutines.

In these examples, CoroutineExceptionHandler is always installed to a coroutine that is created in GlobalScope. It does not make sense to install an exception handler to a coroutine that is launched in the scope of the main runBlocking, since the main coroutine is going to be always cancelled when its child completes with exception despite the installed handler.

The original exception is handled by the parent only when all its children terminate, which is demonstrated by the following example.

```
import kotlinx.coroutines.*

@OptIn(DelicateCoroutinesApi::class)
fun main() = runBlocking {
    val handler = CoroutineExceptionHandler { _, exception ->
        println("CoroutineExceptionHandler got $exception")
    }
    val job = GlobalScope.launch(handler) {
        launch { // the first child
            try {
                delay(Long.MAX_VALUE)
            } finally {
                withContext(NonCancellable) {
                    println("Children are cancelled, but exception is not handled until all children
terminate")
                    delay(100)
                    println("The first child finished its non cancellable block")
                }
            }
        }
        launch { // the second child
            delay(10)
            println("Second child throws an exception")
            throw ArithmeticException()
        }
    }
    job.join()
}
```

You can get the full code here.

The output of this code is:

```
Second child throws an exception
Children are cancelled, but exception is not handled until all children terminate
The first child finished its non cancellable block
CoroutineExceptionHandler got java.lang.ArithmeticException
```

Exceptions aggregation

When multiple children of a coroutine fail with an exception, the general rule is "the first exception wins", so the first exception gets handled. All additional exceptions that happen after the first one are attached to the first exception as suppressed ones.

```
import kotlinx.coroutines.*
import java.io.*

@OptIn(DelicateCoroutinesApi::class)
fun main() = runBlocking {
    val handler = CoroutineExceptionHandler { _, exception ->
        println("CoroutineExceptionHandler got $exception with suppressed
${exception.suppressed.contentToString()}")
    }
    val job = GlobalScope.launch(handler) {
        launch {
            try {
                delay(Long.MAX_VALUE) // it gets cancelled when another sibling fails with IOException
            } finally {
                throw ArithmeticException() // the second exception
            }
        }
        launch {
            delay(100)
            throw IOException() // the first exception
        }
        delay(Long.MAX_VALUE)
    }
    job.join()
}
```

You can get the full code here.

The output of this code is:

```
CoroutineExceptionHandler got java.io.IOException with suppressed [java.lang.ArithmeticException]
```

Note that this mechanism currently only works on Java version 1.7+. The JS and Native restrictions are temporary and will be lifted in the future.

Cancellation exceptions are transparent and are unwrapped by default:

```
import kotlinx.coroutines.*
import java.io.*

@OptIn(DelicateCoroutinesApi::class)
fun main() = runBlocking {
    val handler = CoroutineExceptionHandler { _, exception ->
        println("CoroutineExceptionHandler got $exception")
    }
    val job = GlobalScope.launch(handler) {
        val innerJob = launch { // all this stack of coroutines will get cancelled
            launch {
                launch {
                    throw IOException() // the original exception
                }
            }
        }
        try {
            innerJob.join()
        } catch (e: CancellationException) {
            println("Rethrowing CancellationException with original cause")
            throw e // cancellation exception is rethrown, yet the original IOException gets to the
handler
        }
    }
    job.join()
}
```

You can get the full code here.

The output of this code is:

```
Rethrowing CancellationException with original cause
CoroutineExceptionHandler got java.io.IOException
```

Supervision

As we have studied before, a failure of a coroutine is a bidirectional relationship propagating through the whole hierarchy of coroutines. Let us take a look at the case when unidirectional failure propagation is required.

A good example of such a requirement is a UI component with the job defined in its scope. If any of the UI's child tasks have failed, it is not always necessary to cancel (effectively kill) the whole UI component, but if the UI component is destroyed (and its job is cancelled), then it is necessary to cancel all child jobs as their results are no longer needed.

Another example is a server process that spawns multiple child jobs and needs to *supervise* their execution, tracking their failures and only restarting the failed ones.

Supervision job

The SupervisorJob can be used for these purposes. It is similar to a regular Job with the only exception that a failure or cancellation of a child does not propagate to the supervisor job or its other children. This can easily be demonstrated using the following example:

```
import kotlinx.coroutines.*

fun main() = runBlocking {
    val supervisor = SupervisorJob()
    with(CoroutineScope(coroutineContext + supervisor)) {
        // launch the first child -- its exception is ignored for this example (don't do this in
practice!)
        val firstChild = launch(CoroutineExceptionHandler { _, _ -> }) {
            println("The first child is failing")
            throw AssertionError("The first child is cancelled")
        }
        // launch the second child
        val secondChild = launch {
            firstChild.join()
            // Cancellation of the first child is not propagated to the second child
            println("The first child is cancelled: ${firstChild.isCancelled}, but the second one is
still active")
            try {
                delay(Long.MAX_VALUE)
            } finally {
                // But cancellation of the supervisor is propagated
                println("The second child is cancelled because the supervisor was cancelled")
            }
        }
        // wait until the first child fails & completes
        firstChild.join()
        println("Cancelling the supervisor")
        supervisor.cancel()
        secondChild.join()
    }
}
```

You can get the full code here.

The output of this code is:

```
The first child is failing
The first child is cancelled: true, but the second one is still active
Cancelling the supervisor
The second child is cancelled because the supervisor was cancelled
```

Supervision scope

Instead of coroutineScope, we can use supervisorScope for *scoped* concurrency. It propagates the cancellation in one direction only and cancels all its children only if it failed itself. It also waits for all children before completion just like coroutineScope does.

```
import kotlin.coroutines.*
import kotlinx.coroutines.*

fun main() = runBlocking {
    try {
        supervisorScope {
            val child = launch {
                try {
                    println("The child is sleeping")
                    delay(Long.MAX_VALUE)
                } finally {
                    println("The child is cancelled")
                }
            }
            // Give our child a chance to execute and print using yield
            yield()
            println("Throwing an exception from the scope")
            throw AssertionError()
        }
    } catch(e: AssertionError) {
        println("Caught an assertion error")
    }
}
```

You can get the full code here.

The output of this code is:

```
The child is sleeping
Throwing an exception from the scope
The child is cancelled
Caught an assertion error
```

Exceptions in supervised coroutines

Another crucial difference between regular and supervisor jobs is exception handling. Every child should handle its exceptions by itself via the exception handling mechanism. This difference comes from the fact that child's failure does not propagate to the parent. It means that coroutines launched directly inside the supervisorScope *do* use the CoroutineExceptionHandler that is installed in their scope in the same way as root coroutines do (see the CoroutineExceptionHandler section for details).

```
import kotlin.coroutines.*
import kotlinx.coroutines.*

fun main() = runBlocking {
    val handler = CoroutineExceptionHandler { _, exception ->
        println("CoroutineExceptionHandler got $exception")
    }
    supervisorScope {
        val child = launch(handler) {
            println("The child throws an exception")
            throw AssertionError()
        }
        println("The scope is completing")
    }
    println("The scope is completed")
}
```

You can get the full code here.

The output of this code is:

```
The scope is completing
The child throws an exception
CoroutineExceptionHandler got java.lang.AssertionError
The scope is completed
```

Shared mutable state and concurrency

Coroutines can be executed parallelly using a multi-threaded dispatcher like the Dispatchers.Default. It presents all the usual parallelism problems. The main problem being synchronization of access to **shared mutable state**. Some solutions to this problem in the land of coroutines are similar to the solutions in the multi-threaded world, but others are unique.

The problem

Let us launch a hundred coroutines all doing the same action a thousand times. We'll also measure their completion time for further comparisons:

```
suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}
```

We start with a very simple action that increments a shared mutable variable using multi-threaded Dispatchers.Default.

```
import kotlinx.coroutines.*
import kotlin.system.*

suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}

var counter = 0

fun main() = runBlocking {
    withContext(Dispatchers.Default) {
        massiveRun {
            counter++
        }
    }
    println("Counter = $counter")
}
```

You can get the full code here.

What does it print at the end? It is highly unlikely to ever print "Counter = 100000", because a hundred coroutines increment the `counter` concurrently from multiple threads without any synchronization.

Volatiles are of no help

There is a common misconception that making a variable `volatile` solves concurrency problem. Let us try it:

```
import kotlinx.coroutines.*
import kotlin.system.*

suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}

@Volatile // in Kotlin `volatile` is an annotation
var counter = 0

fun main() = runBlocking {
    withContext(Dispatchers.Default) {
        massiveRun {
            counter++
        }
    }
    println("Counter = $counter")
}
```

You can get the full code here.

This code works slower, but we still don't always get "Counter = 100000" at the end, because volatile variables guarantee linearizable (this is a technical term for "atomic") reads and writes to the corresponding variable, but do not provide atomicity of larger actions (increment in our case).

Thread-safe data structures

The general solution that works both for threads and for coroutines is to use a thread-safe (aka synchronized, linearizable, or atomic) data structure that provides all the necessary synchronization for the corresponding operations that needs to be performed on a shared state. In the case of a simple counter we can use `AtomicInteger` class which has atomic `incrementAndGet` operations:

```
import kotlinx.coroutines.*
import java.util.concurrent.atomic.*
import kotlin.system.*

suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}

val counter = AtomicInteger()

fun main() = runBlocking {
    withContext(Dispatchers.Default) {
        massiveRun {
            counter.incrementAndGet()
        }
    }
    println("Counter = $counter")
}
```

You can get the full code here.

This is the fastest solution for this particular problem. It works for plain counters, collections, queues and other standard data structures and basic operations on them. However, it does not easily scale to complex state or to complex operations that do not have ready-to-use thread-safe implementations.

Thread confinement fine-grained

Thread confinement is an approach to the problem of shared mutable state where all access to the particular shared state is confined to a single thread. It is typically used in UI applications, where all UI state is confined to the single event-dispatch/application thread. It is easy to apply with coroutines by using a single-threaded context.

```
import kotlinx.coroutines.*
import kotlin.system.*

suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}

val counterContext = newSingleThreadContext("CounterContext")
var counter = 0

fun main() = runBlocking {
    withContext(Dispatchers.Default) {
        massiveRun {
            // confine each increment to a single-threaded context
            withContext(counterContext) {
                counter++
            }
        }
    }
    println("Counter = $counter")
}
```

You can get the full code here.

This code works very slowly, because it does *fine-grained* thread-confinement. Each individual increment switches from multi-threaded Dispatchers.Default context to the single-threaded context using withContext(counterContext) block.

Thread confinement coarse-grained

In practice, thread confinement is performed in large chunks, e.g. big pieces of state-updating business logic are confined to the single thread. The following example does it like that, running each coroutine in the single-threaded context to start with.

```
import kotlinx.coroutines.*
import kotlin.system.*

suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}

val counterContext = newSingleThreadContext("CounterContext")
var counter = 0

fun main() = runBlocking {
    // confine everything to a single-threaded context
    withContext(counterContext) {
        massiveRun {
            counter++
        }
    }
    println("Counter = $counter")
}
```

You can get the full code here.

This now works much faster and produces correct result.

Mutual exclusion

Mutual exclusion solution to the problem is to protect all modifications of the shared state with a *critical section* that is never executed concurrently. In a blocking world you'd typically use `synchronized` or `ReentrantLock` for that. Coroutine's alternative is called Mutex. It has lock and unlock functions to delimit a critical section. The key difference is that `Mutex.lock()` is a suspending function. It does not block a thread.

There is also withLock extension function that conveniently represents `mutex.lock(); try { ... } finally { mutex.unlock() }` pattern:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.sync.*
import kotlin.system.*

suspend fun massiveRun(action: suspend () -> Unit) {
    val n = 100  // number of coroutines to launch
    val k = 1000 // times an action is repeated by each coroutine
    val time = measureTimeMillis {
        coroutineScope { // scope for coroutines
            repeat(n) {
                launch {
                    repeat(k) { action() }
                }
            }
        }
    }
    println("Completed ${n * k} actions in $time ms")
}

val mutex = Mutex()
var counter = 0

fun main() = runBlocking {
    withContext(Dispatchers.Default) {
        massiveRun {
            // protect each increment with lock
            mutex.withLock {
                counter++
            }
        }
    }
    println("Counter = $counter")
}
```

You can get the full code here.

The locking in this example is fine-grained, so it pays the price. However, it is a good choice for some situations where you absolutely must modify some shared state periodically, but there is no natural thread that this state is confined to.

Select expression (experimental)

Select expression makes it possible to await multiple suspending functions simultaneously and *select* the first one that becomes available.

Select expressions are an experimental feature of `kotlinx.coroutines`. Their API is expected to evolve in the upcoming updates of the `kotlinx.coroutines` library with potentially breaking changes.

Selecting from channels

Let us have two producers of strings: `fizz` and `buzz`. The `fizz` produces "Fizz" string every 500 ms:

```
fun CoroutineScope.fizz() = produce<String> {
    while (true) { // sends "Fizz" every 500 ms
        delay(500)
        send("Fizz")
    }
}
```

And the `buzz` produces "Buzz!" string every 1000 ms:

```
fun CoroutineScope.buzz() = produce<String> {
    while (true) { // sends "Buzz!" every 1000 ms
        delay(1000)
        send("Buzz!")
    }
}
```

Using receive suspending function we can receive *either* from one channel or the other. But select expression allows us to receive from *both* simultaneously using its onReceive clauses:

```
suspend fun selectFizzBuzz(fizz: ReceiveChannel<String>, buzz: ReceiveChannel<String>) {
    select<Unit> { // <Unit> means that this select expression does not produce any result
        fizz.onReceive { value ->  // this is the first select clause
            println("fizz -> '$value'")
        }
        buzz.onReceive { value ->  // this is the second select clause
            println("buzz -> '$value'")
        }
    }
}
```

Let us run it all seven times:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*
import kotlinx.coroutines.selects.*

fun CoroutineScope.fizz() = produce<String> {
    while (true) { // sends "Fizz" every 500 ms
        delay(500)
        send("Fizz")
    }
}

fun CoroutineScope.buzz() = produce<String> {
    while (true) { // sends "Buzz!" every 1000 ms
        delay(1000)
        send("Buzz!")
    }
}

suspend fun selectFizzBuzz(fizz: ReceiveChannel<String>, buzz: ReceiveChannel<String>) {
    select<Unit> { // <Unit> means that this select expression does not produce any result
        fizz.onReceive { value ->  // this is the first select clause
            println("fizz -> '$value'")
        }
        buzz.onReceive { value ->  // this is the second select clause
            println("buzz -> '$value'")
        }
    }
}

fun main() = runBlocking<Unit> {
    val fizz = fizz()
    val buzz = buzz()
    repeat(7) {
        selectFizzBuzz(fizz, buzz)
    }
    coroutineContext.cancelChildren() // cancel fizz & buzz coroutines
}
```

You can get the full code here.

The result of this code is:

```
fizz -> 'Fizz'
buzz -> 'Buzz!'
fizz -> 'Fizz'
fizz -> 'Fizz'
buzz -> 'Buzz!'
fizz -> 'Fizz'
fizz -> 'Fizz'
```

Selecting on close

The onReceive clause in `select` fails when the channel is closed causing the corresponding `select` to throw an exception. We can use onReceiveCatching clause to perform a specific action when the channel is closed. The following example also shows that `select` is an expression that returns the result of its selected clause:

```
suspend fun selectAorB(a: ReceiveChannel<String>, b: ReceiveChannel<String>): String =
    select<String> {
        a.onReceiveCatching { it →
            val value = it.getOrNull()
            if (value ≠ null) {
                "a → '$value'"
            } else {
                "Channel 'a' is closed"
            }
        }
        b.onReceiveCatching { it →
            val value = it.getOrNull()
            if (value ≠ null) {
                "b → '$value'"
            } else {
                "Channel 'b' is closed"
            }
        }
    }
```

Let's use it with channel `a` that produces "Hello" string four times and channel `b` that produces "World" four times:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*
import kotlinx.coroutines.selects.*

suspend fun selectAorB(a: ReceiveChannel<String>, b: ReceiveChannel<String>): String =
    select<String> {
        a.onReceiveCatching { it →
            val value = it.getOrNull()
            if (value ≠ null) {
                "a → '$value'"
            } else {
                "Channel 'a' is closed"
            }
        }
        b.onReceiveCatching { it →
            val value = it.getOrNull()
            if (value ≠ null) {
                "b → '$value'"
            } else {
                "Channel 'b' is closed"
            }
        }
    }

fun main() = runBlocking<Unit> {
    val a = produce<String> {
        repeat(4) { send("Hello $it") }
    }
    val b = produce<String> {
        repeat(4) { send("World $it") }
    }
    repeat(8) { // print first eight results
        println(selectAorB(a, b))
    }
    coroutineContext.cancelChildren()
}
```

You can get the full code here.

The result of this code is quite interesting, so we'll analyze it in more detail:

```
a → 'Hello 0'
a → 'Hello 1'
b → 'World 0'
a → 'Hello 2'
a → 'Hello 3'
b → 'World 1'
Channel 'a' is closed
Channel 'a' is closed
```

There are a couple of observations to make out of it.

First of all, `select` is *biased* to the first clause. When several clauses are selectable at the same time, the first one among them gets selected. Here, both channels are constantly producing strings, so `a` channel, being the first clause in select, wins. However, because we are using unbuffered channel, the `a` gets suspended from time to time on its send invocation and gives a chance for `b` to send, too.

The second observation, is that onReceiveCatching gets immediately selected when the channel is already closed.

Selecting to send

Select expression has onSend clause that can be used for a great good in combination with a biased nature of selection.

Let us write an example of a producer of integers that sends its values to a `side` channel when the consumers on its primary channel cannot keep up with it:

```
fun CoroutineScope.produceNumbers(side: SendChannel<Int>) = produce<Int> {
    for (num in 1..10) { // produce 10 numbers from 1 to 10
        delay(100) // every 100 ms
        select<Unit> {
            onSend(num) {} // Send to the primary channel
            side.onSend(num) {} // or to the side channel
        }
    }
}
```

Consumer is going to be quite slow, taking 250 ms to process each number:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*
import kotlinx.coroutines.selects.*

fun CoroutineScope.produceNumbers(side: SendChannel<Int>) = produce<Int> {
    for (num in 1..10) { // produce 10 numbers from 1 to 10
        delay(100) // every 100 ms
        select<Unit> {
            onSend(num) {} // Send to the primary channel
            side.onSend(num) {} // or to the side channel
        }
    }
}

fun main() = runBlocking<Unit> {
    val side = Channel<Int>() // allocate side channel
    launch { // this is a very fast consumer for the side channel
        side.consumeEach { println("Side channel has $it") }
    }
    produceNumbers(side).consumeEach {
        println("Consuming $it")
        delay(250) // let us digest the consumed number properly, do not hurry
    }
    println("Done consuming")
    coroutineContext.cancelChildren()
}
```

You can get the full code here.

So let us see what happens:

```
Consuming 1
Side channel has 2
Side channel has 3
Consuming 4
Side channel has 5
Side channel has 6
Consuming 7
Side channel has 8
Side channel has 9
Consuming 10
Done consuming
```

Selecting deferred values

Deferred values can be selected using onAwait clause. Let us start with an async function that returns a deferred string value after a random delay:

```
fun CoroutineScope.asyncString(time: Int) = async {
    delay(time.toLong())
    "Waited for $time ms"
}
```

Let us start a dozen of them with a random delay.

```
fun CoroutineScope.asyncStringsList(): List<Deferred<String>> {
    val random = Random(3)
    return List(12) { asyncString(random.nextInt(1000)) }
}
```

Now the main function awaits for the first of them to complete and counts the number of deferred values that are still active. Note that we've used here the fact that `select` expression is a Kotlin DSL, so we can provide clauses for it using an arbitrary code. In this case we iterate over a list of deferred values to provide `onAwait` clause for each deferred value.

```
import kotlinx.coroutines.*
import kotlinx.coroutines.selects.*
import java.util.*

fun CoroutineScope.asyncString(time: Int) = async {
    delay(time.toLong())
    "Waited for $time ms"
}

fun CoroutineScope.asyncStringsList(): List<Deferred<String>> {
    val random = Random(3)
    return List(12) { asyncString(random.nextInt(1000)) }
}

fun main() = runBlocking<Unit> {
    val list = asyncStringsList()
    val result = select<String> {
        list.withIndex().forEach { (index, deferred) ->
            deferred.onAwait { answer ->
                "Deferred $index produced answer '$answer'"
            }
        }
    }
    println(result)
    val countActive = list.count { it.isActive }
    println("$countActive coroutines are still active")
}
```

You can get the full code here.

The output is:

```
Deferred 4 produced answer 'Waited for 128 ms'
11 coroutines are still active
```

Switch over a channel of deferred values

Let us write a channel producer function that consumes a channel of deferred string values, waits for each received deferred value, but only until the next deferred value comes over or the channel is closed. This example puts together onReceiveCatching and onAwait clauses in the same `select` :

```
fun CoroutineScope.switchMapDeferreds(input: ReceiveChannel<Deferred<String>>) = produce<String> {
    var current = input.receive() // start with first received deferred value
    while (isActive) { // loop while not cancelled/closed
        val next = select<Deferred<String>?> { // return next deferred value from this select or null
            input.onReceiveCatching { update ->
                update.getOrNull()
            }
            current.onAwait { value ->
                send(value) // send value that current deferred has produced
                input.receiveCatching().getOrNull() // and use the next deferred from the input
channel
            }
        }
        if (next == null) {
            println("Channel was closed")
            break // out of loop
        } else {
            current = next
        }
    }
}
```

To test it, we'll use a simple async function that resolves to a specified string after a specified time:

```
fun CoroutineScope.asyncString(str: String, time: Long) = async {
    delay(time)
    str
}
```

The main function just launches a coroutine to print results of `switchMapDeferreds` and sends some test data to it:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.channels.*
import kotlinx.coroutines.selects.*

fun CoroutineScope.switchMapDeferreds(input: ReceiveChannel<Deferred<String>>) = produce<String> {
    var current = input.receive() // start with first received deferred value
    while (isActive) { // loop while not cancelled/closed
        val next = select<Deferred<String>?> { // return next deferred value from this select or null
            input.onReceiveCatching { update ->
                update.getOrNull()
            }
            current.onAwait { value ->
                send(value) // send value that current deferred has produced
                input.receiveCatching().getOrNull() // and use the next deferred from the input
channel
            }
        }
        if (next == null) {
            println("Channel was closed")
            break // out of loop
        } else {
            current = next
        }
    }
}

fun CoroutineScope.asyncString(str: String, time: Long) = async {
    delay(time)
    str
}

fun main() = runBlocking<Unit> {
    val chan = Channel<Deferred<String>>() // the channel for test
    launch { // launch printing coroutine
        for (s in switchMapDeferreds(chan))
            println(s) // print each received string
    }
    chan.send(asyncString("BEGIN", 100))
    delay(200) // enough time for "BEGIN" to be produced
    chan.send(asyncString("Slow", 500))
    delay(100) // not enough time to produce slow
    chan.send(asyncString("Replace", 100))
    delay(500) // give it time before the last one
    chan.send(asyncString("END", 500))
    delay(1000) // give it time to process
    chan.close() // close the channel ...
    delay(500) // and wait some time to let it finish
}
```

You can get the full code here.

The result of this code:

```
BEGIN
Replace
END
Channel was closed
```

Debug coroutines

Debugging applications that use coroutines can be challenging because multiple coroutines can run concurrently, suspend on one thread, and resume on another. Their execution order and the threads they use can also change between runs, making it difficult to follow the execution of a particular coroutine.

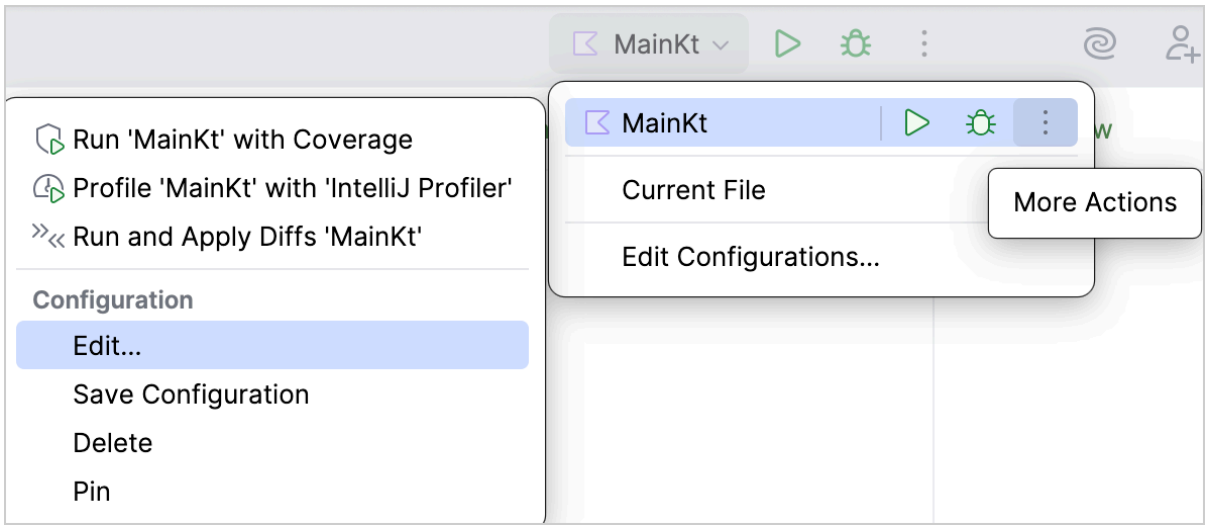
On the JVM, you can use the following features to make debugging coroutines easier:

- Debug mode adds a unique name to each coroutine so you can identify it in a debugger and diagnostic output.
- Stack trace recovery adds information about where a coroutine receives an exception instead of an expected result.
- The debug agent tracks active coroutines, reports their state, and more.

Debug mode and stack trace recovery are available in the `kotlinx-coroutines-core` module. The debug agent is available in the `kotlinx-coroutines-debug` module.

> The debug agent isn't supported on Android.

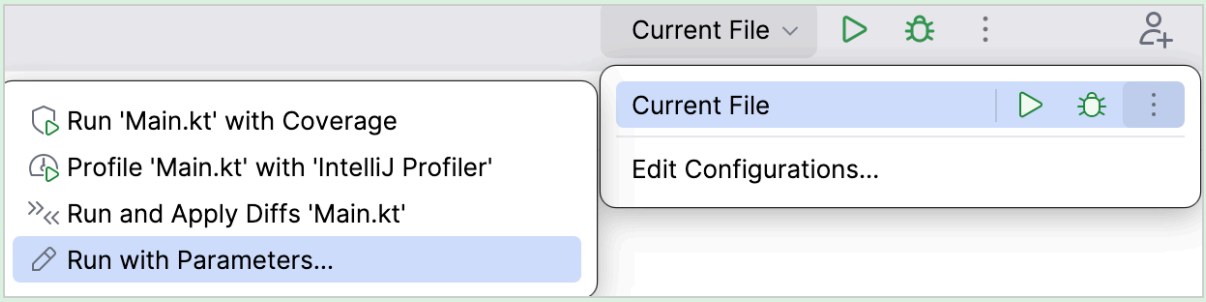
Enable debug mode



Debug mode assigns a unique name to every launched coroutine. You can see the coroutine names in a Java debugger, in the coroutine's string representation, and in a thread's name while it runs the coroutine. Debug mode has negligible runtime overhead, so you can keep it enabled to simplify logging and diagnostics.

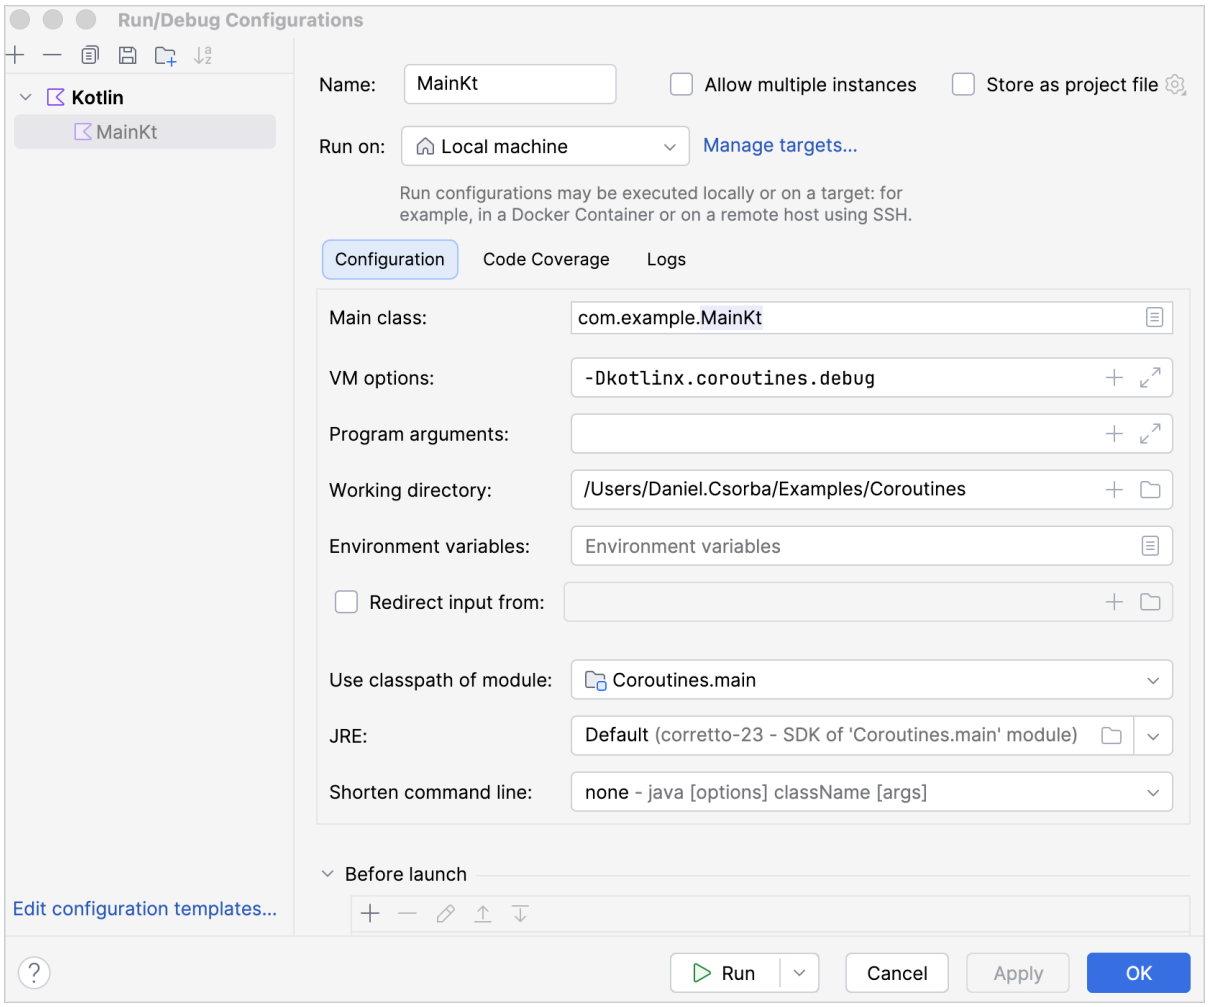
When you run your code with Java assertions enabled, the `kotlinx.coroutines` library automatically enables debug mode. Unit tests run with assertions enabled by default, so you don't need to enable debug mode explicitly for them.

To enable debug mode explicitly, configure your build tool, such as Gradle or Maven, or IDE run configuration to pass the `-Dkotlinx.coroutines.debug` argument to the JVM that runs your application.



In IntelliJ IDEA, follow these steps to enable debug mode:

1. In the **Run widget**, select the run/debug configuration you want to update, then select **More Actions** | **Edit**:



Selecting Edit from the More Actions menu for a run configuration in IntelliJ IDEA

If you don't have a run/debug configuration, select **Current File** in the **Run widget**, then select **More Actions** | **Run with Parameters** to open the run configuration settings.

Selecting Run with Parameters from the More Actions menu for a run configuration in IntelliJ IDEA

2. In the **Run/Debug Configurations** dialog, enter `-Dkotlinx.coroutines.debug` in the **VM options** field, and click **OK**:

Adding the -Dkotlinx.coroutines.debug option to a run/debug configuration in IntelliJ IDEA

Stack trace recovery

When a coroutine receives an exception from another coroutine through a suspending function such as `Deferred.await()`, the exception's stack trace doesn't contain the stack frames from the receiving coroutine.

Without these stack frames, the stack trace doesn't show where `Deferred.await()` is called or which functions lead to that call, which can make debugging difficult.

The `kotlinx.coroutines` library adds this information using *stack trace recovery*, which creates a copy of the exception with additional stack frames.

When the receiving coroutine resumes, it throws the copy instead of the original exception. The original exception becomes the cause of the copy. If the original exception has suppressed exceptions, they remain attached to it instead of being copied. Keeping them attached to the original exception can prevent cycles in the exception chain and crashes in some frameworks.

Debug mode enables stack trace recovery by default. To disable stack trace recovery in debug mode, pass the `-Dkotlinx.coroutines.stacktrace.recovery=false` VM option.

Here's an example to demonstrate the difference between stack traces with and without stack trace recovery:

```
import kotlinx.coroutines.*

object UserProfileService :
    CoroutineScope by CoroutineScope(CoroutineName("UserProfileService")) {

    private fun parseUserProfile(): String {
        error("Invalid user profile")
    }

    private fun loadUserProfile(): String {
        return parseUserProfile()
    }

    // Runs in the coroutine that calls this function
    suspend fun awaitUserProfile() {
        // Starts a new coroutine
        val userProfile = async(Dispatchers.Default) {
            // The new coroutine throws the exception
            loadUserProfile()
        }

        // The coroutine running awaitUserProfile()
        // receives the exception through the await() function
        userProfile.await()
    }
}

suspend fun main() {
    UserProfileService.awaitUserProfile()
}
```

In this example, the `parseUserProfile()` function throws the exception in the coroutine started by the `.async()` builder function. The coroutine that calls `awaitUserProfile()` receives the exception through the `Deferred.await()` function.

With stack trace recovery disabled, the stack trace shows where `parseUserProfile()` throws the exception in the coroutine created by the `.async()` function, but it doesn't include the `Deferred.await()` call in the `awaitUserProfile()` function:

```
Exception in thread "main" java.lang.IllegalStateException Create breakpoint : Invalid user profile
    at com.example.UserProfileService.parseUserProfile(RecoveryExample.kt:9)
    at com.example.UserProfileService.loadUserProfile(RecoveryExample.kt:13)
    at com.example.UserProfileService.access$loadUserProfile(RecoveryExample.kt:5)
    at com.example.UserProfileService$awaitUserProfile$userProfile$1.invokeSuspend(RecoveryExample.kt:18)
    at kotlin.coroutines.jvm.internal.BaseContinuationImpl.resumeWith(ContinuationImpl.kt:34)
    at kotlinx.coroutines.DispatchedTask.run(DispatchedTask.kt:100)
    at kotlinx.coroutines.scheduling.CoroutineScheduler.runSafely(CoroutineScheduler.kt:586)
    at kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.executeTask(CoroutineScheduler.kt:807)
    at kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.runWorker(CoroutineScheduler.kt:717)
    at kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.run(CoroutineScheduler.kt:704)
```

Exception stack trace without stack frames from the receiving coroutine

With stack trace recovery enabled, the stack trace also includes the `Deferred.await()` call in the `awaitUserProfile()` function:

```
Exception in thread "main" java.lang.IllegalStateException Create breakpoint : Invalid user profile
    at com.example.UserProfileService.parseUserProfile(RecoveryExample.kt:9)
    at com.example.UserProfileService.loadUserProfile(RecoveryExample.kt:13)

    at kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.runWorker(CoroutineScheduler.kt:717)
    at kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.run(CoroutineScheduler.kt:704)
```

Recovered exception stack trace with stack frames from the receiving coroutine

Experimental

Stack trace recovery for custom exceptions

Stack trace recovery can copy an exception automatically when its class has a public constructor that accepts a message, a cause, both, or no arguments at all.

If you want the `kotlinx.coroutines` library to recover the stack trace of an exception that requires additional constructor arguments, such as a line number or an error code, implement the `StackTraceRecoverable` interface.

The `StackTraceRecoverable` interface is part of the Kotlin standard library, so you can implement it without adding a dependency on the `kotlinx.coroutines` library.

> The `StackTraceRecoverable` interface is available on all targets, but the `kotlinx.coroutines` library uses it for stack trace recovery only on the JVM.

To implement the interface, override the `copyForStackTraceRecovery()` function. In the override, return a new exception instance for stack trace recovery, or `null` if you don't want the `kotlinx.coroutines` library to copy the exception.

These APIs are Experimental and require opt-in with the `@OptIn(ExperimentalStdlibCoroutineSupportApi::class)` annotation.

Here's an example of a custom exception that preserves a `line` property when it creates a new instance for stack trace recovery:

```
import kotlinx.coroutines.*
import kotlin.coroutines.ExperimentalStdlibCoroutineSupportApi
import kotlin.coroutines.debug.StackTraceRecoverable

@OptIn(ExperimentalStdlibCoroutineSupportApi::class)
class FileEditException
// The implementation requires a private constructor
// to pass the cause to the IllegalStateException constructor
private constructor(
    val line: Int,
    private val detail: String,
    cause: Throwable?,
) : IllegalStateException("When editing line $line: $detail", cause),
    // Implements StackTraceRecoverable for stack trace recovery
    StackTraceRecoverable<FileEditException> {

    constructor(line: Int, detail: String) : this(line, detail, null)

    // Copies the line number and message details
    override fun copyForStackTraceRecovery(): FileEditException =
        FileEditException(line, detail, this)
}

private fun editFile() {
    throw FileEditException(15, "Unexpected token")
}

suspend fun main() {
    supervisorScope {
        // Starts a new coroutine
        val fileEdit = async(Dispatchers.Default) {
            // Throws the original exception
            editFile()
        }

        // Stack trace recovery creates a copy of the exception,
        // adds the calling coroutine's stack frames, and throws the copy
        fileEdit.await()
    }
}
```

With debug mode enabled, the output contains the recovered copy followed by the original exception as its cause.

```
Exception in thread "main" com.example.FileEditException: When editing line 15: Unexpected token
        at com.example.RecoveryExampleKt.editFile(RecoveryExample.kt:54)

kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.runWorker(CoroutineScheduler.kt:717)
        at kotlinx.coroutines.scheduling.CoroutineScheduler$Worker.run(CoroutineScheduler.kt:704)
```

Experimental

The debug agent

The `kotlinx-coroutines-debug` module provides a debug agent for JVM applications. The agent tracks coroutines as they are created, suspended, and resumed.

The `DebugProbes` API is the main entry point for the debug agent. You can use it to print active coroutines and their current state. The output includes stack traces that show where each coroutine was created and where it is suspended. You can also use it to print a coroutine dump for the hierarchy of a specific `Job` or `CoroutineScope`.

If you enable `DebugProbes` in a production environment, it can significantly reduce your application's performance when it creates a stack trace for each new coroutine. To avoid this overhead, set `DebugProbes.enableCreationStackTraces` to `false`.

> The `kotlinx-coroutines-debug` module provides automatic BlockHound integration. You can use it to detect blocking operations in coroutine contexts where they aren't allowed.
>
> For setup instructions, see the BlockHound quick start guide.

Add the debug agent dependency

To use the debug agent in your project, add the `kotlinx-coroutines-debug` dependency:

Gradle

```
// build.gradle.kts
dependencies {
    testImplementation("org.jetbrains.kotlinx:kotlinx-coroutines-debug:1.11.0")
}
```

Maven

```
<!-- pom.xml -->
<dependency>
    <groupId>org.jetbrains.kotlinx</groupId>
    <artifactId>kotlinx-coroutines-debug</artifactId>
    <version>1.11.0</version>
    <scope>test</scope>
</dependency>
```

Track coroutines with the debug agent

To start tracking coroutines with the debug agent, you can either:

- Add `-javaagent:/path/to/kotlinx-coroutines-debug-1.11.0.jar` to your VM options to load the debug agent when the application starts.
- Call the `DebugProbes.install()` function before starting the coroutines you want to track.

Starting with JDK 21, dynamically loading the debug agent with the `DebugProbes.install()` function can produce a warning. To avoid this warning, load the agent with the `-javaagent` VM option.

With the debug agent active, you can use the following APIs:

- `DebugProbes.dumpCoroutines()` prints all active coroutines.
- `DebugProbes.dumpCoroutinesInfo()` returns information about active coroutines.
- `DebugProbes.printJob()` prints a coroutine dump for the hierarchy of a `Job`.
- `DebugProbes.printScope()` prints a coroutine dump for the hierarchy of a `CoroutineScope`.

Here's an example that uses the debug agent to print active coroutines and the coroutine hierarchy for a specific `Job`:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.debug.*
import kotlin.time.Duration.Companion.seconds

private suspend fun loadAccount() {
    delay(5.seconds)
}

private suspend fun loadPreferences() {
    delay(5.seconds)
}

private suspend fun loadUserProfile() = coroutineScope {
    launch { loadAccount() }
    launch { loadPreferences() }
}

@OptIn(ExperimentalCoroutinesApi::class)
fun main() {
    // Installs the debug agent
    // This is only required if you don't use the -javaagent VM option
    DebugProbes.install()

    runBlocking {
        // Starts a coroutine with two child coroutines
        val loadingJob = launch {
            loadUserProfile()
        }

        // Gives the child coroutines time to suspend
        delay(1.seconds)

        // Prints all active coroutines
        DebugProbes.dumpCoroutines()

        println("=============")

        // Prints the loading job and its child coroutines
        DebugProbes.printJob(loadingJob)
    }
}
```

With debug mode enabled, running the example produces the following output:

```
Coroutines dump 2026/08/18 14:00:08

```

Print active coroutines when JUnit tests time out

You can set a timeout for JUnit tests with the corresponding `CoroutinesTimeout` API, depending on the JUnit version. The API installs debug probes automatically. If a test doesn't complete before the timeout, it prints all active coroutines and their stack traces and fails the test.

JUnit 4

To set a timeout for JUnit 4 tests and print all active coroutines and their stack traces if they exceed it, use the `CoroutinesTimeout` rule:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.debug.junit4.CoroutinesTimeout
import org.junit.Rule
import org.junit.Test
import kotlin.time.Duration

@OptIn(ExperimentalCoroutinesApi::class)
class UserProfileTest {
    @get:Rule
    val timeout = CoroutinesTimeout.seconds(1)

    private suspend fun loadUserProfile() {
        withContext(Dispatchers.IO) {
            // Simulates an operation that doesn't complete
            delay(Duration.INFINITE)
        }
    }

    @Test
    fun loadsUserProfile() = runBlocking {
        val loadingJob = launch {
            loadUserProfile()
        }

        // Waits for the coroutine, so the test doesn't complete
        loadingJob.join()
    }
}
```

After one second, the rule reports that the test timed out and prints all active coroutines and their stack traces. The test then fails with a `TestTimedOutException`.

```
Test loadsUserProfile timed out after 1 seconds

```

JUnit 5

To apply a timeout to all test functions in a class, add the `@CoroutinesTimeout` annotation to the class:

```
import kotlinx.coroutines.*
import kotlinx.coroutines.debug.junit5.CoroutinesTimeout
import org.junit.jupiter.api.Test
import kotlin.time.Duration

@OptIn(ExperimentalCoroutinesApi::class)
// Sets a one-second timeout for all test functions in the class
@CoroutinesTimeout(testTimeoutMs = 1_000)
class UserProfileTest {
    private suspend fun loadUserProfile() {
        withContext(Dispatchers.IO) {
            // Simulates an operation that doesn't complete
            delay(Duration.INFINITE)
        }
    }

    @Test
    fun loadsUserProfile() = runBlocking {
        val loadingJob = launch {
            loadUserProfile()
        }

        // Waits for the coroutine, so the test doesn't complete
        loadingJob.join()
    }
}
```

After one second, the `CoroutinesTimeout` API reports the timeout and prints all active coroutines and their stack traces. The test then fails with a `CoroutinesTimeoutException`.

```
Test loadsUserProfile timed out after 1 seconds

Resolve `kotlinx-coroutines-debug` resource conflicts on Android

The debug agent isn't supported on Android.

The `kotlinx-coroutines-debug` module has transitive dependencies on JNA, JNA Platform, Byte Buddy, and Byte Buddy Agent. Some of these dependencies contain resources with the same paths. When Android merges dependency resources, the duplicate paths can cause a `DuplicateRelativeFileException` resulting in a build failure.

To resolve the build failure while keeping the `kotlinx-coroutines-debug` dependency, exclude the conflicting resources with the following `packaging` configuration in your `build.gradle.kts` file:

```
// build.gradle.kts
android {
    packaging {
        resources {
            // Excludes license files from JNA and JNA Platform
            excludes += setOf(
                "META-INF/AL2.0",
                "META-INF/LGPL2.1",
            )

            // Excludes the ASM license file from Byte Buddy
            excludes += "META-INF/licenses/ASM"

            // Retains one copy of each Byte Buddy Agent file
            pickFirsts += setOf(
                "win32-x86-64/attach_hotspot_windows.dll",
                "win32-x86/attach_hotspot_windows.dll",
            )
        }
    }
}
```

What's next

Learn how to debug coroutines in IntelliJ IDEA in Debug coroutines using IntelliJ IDEA and Debug Kotlin Flow using IntelliJ IDEA.

Debug coroutines using IntelliJ IDEA – tutorial

This tutorial demonstrates how to create Kotlin coroutines and debug them using IntelliJ IDEA.

The tutorial assumes you have prior knowledge of the coroutines concept.

Create coroutines

1. Open a Kotlin project in IntelliJ IDEA. If you don't have a project, create one.
2. To use the `kotlinx.coroutines` library in a Gradle project, add the following dependency to `build.gradle(.kts)`:

Kotlin

```
dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
}
```

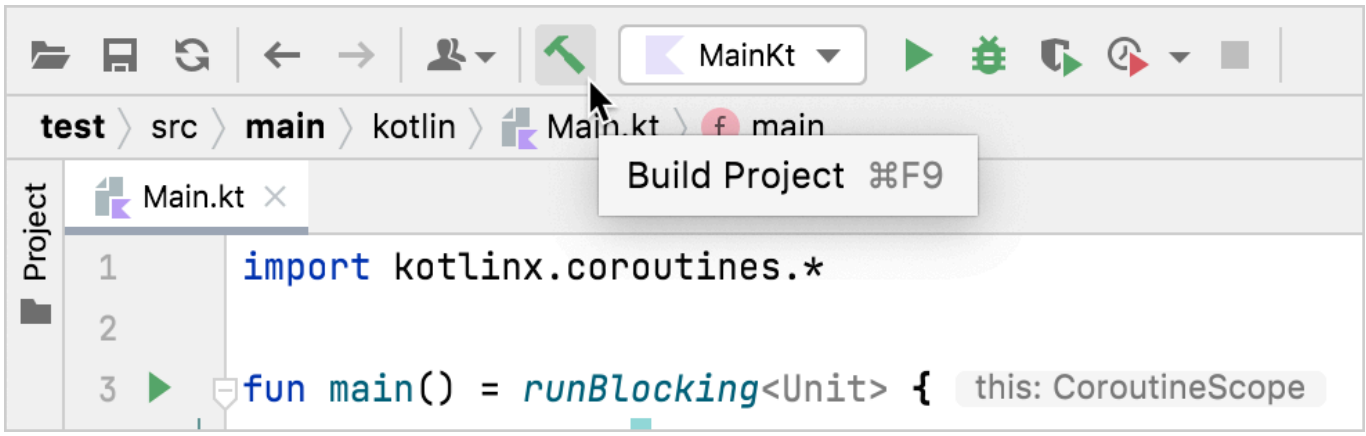
Groovy

```
dependencies {
    implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
}
```

For other build systems, see instructions in the `kotlinx.coroutines` README.

3. Open the `Main.kt` file in `src/main/kotlin`.

   The `src` directory contains Kotlin source files and resources. The `Main.kt` file contains sample code that will print `Hello World!`.

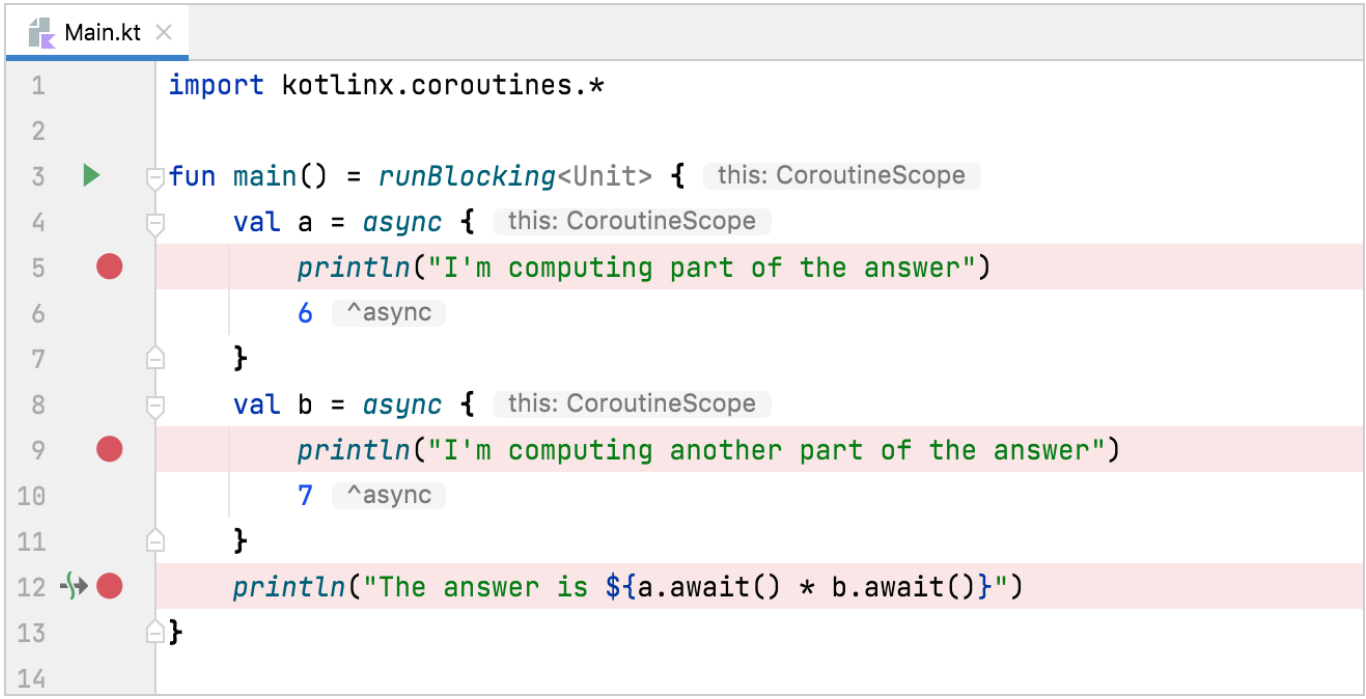


4. Change code in the `main()` function:

   - Use the `runBlocking()` block to wrap a coroutine.
   - Use the `async()` function to create coroutines that compute deferred values `a` and `b`.
   - Use the `await()` function to await the computation result.
   - Use the `println()` function to print computing status and the result of multiplication to the output.

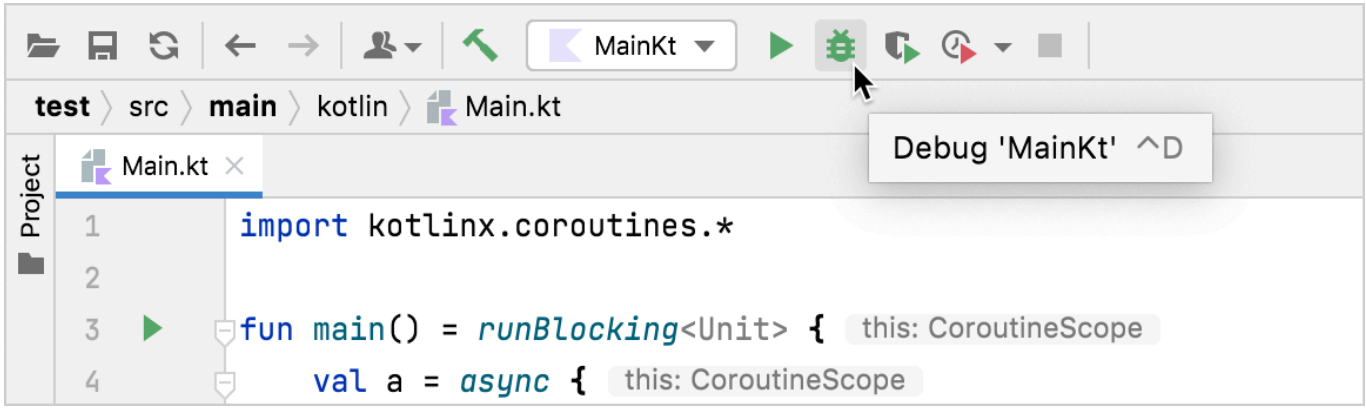
```
import kotlinx.coroutines.*

fun main() = runBlocking<Unit> {
    val a = async {
        println("I'm computing part of the answer")
        6
    }
    val b = async {
        println("I'm computing another part of the answer")
        7
    }
    println("The answer is ${a.await() * b.await()}")
}
```



5. Build the code by clicking **Build Project**.

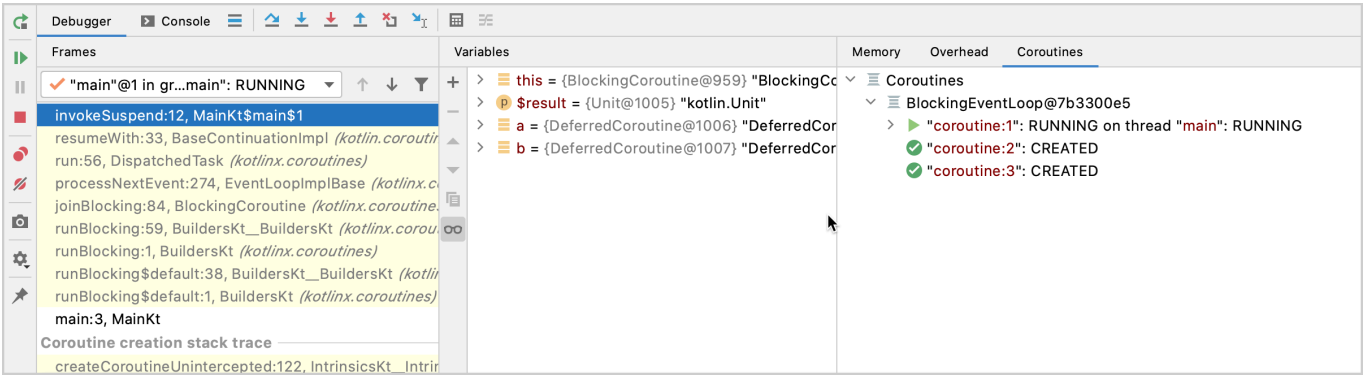
Build an application



Debug coroutines

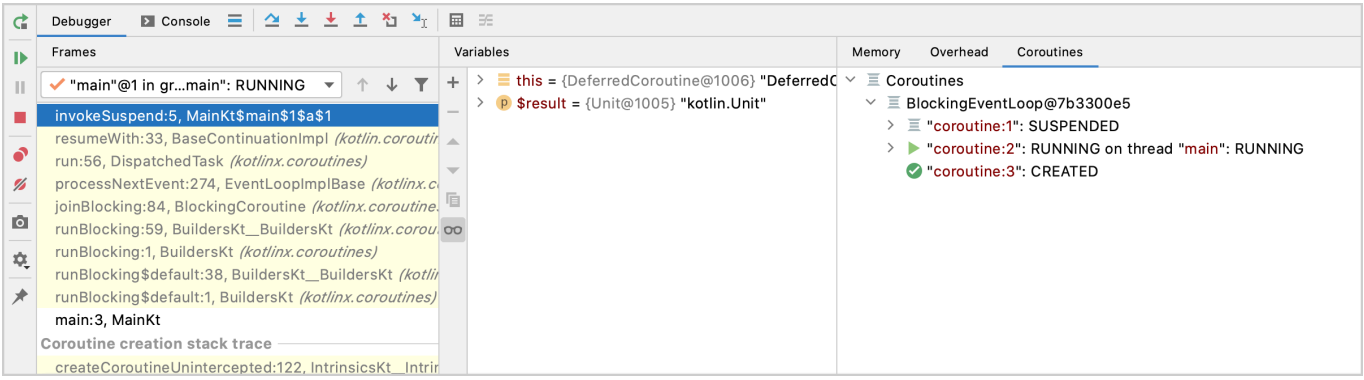
1. Set breakpoints at the lines with the `println()` function call:

Build a console application



2. Run the code in debug mode by clicking **Debug** next to the run configuration at the top of the screen.

Build a console application



The **Debug** tool window appears:

- The **Frames** tab contains the call stack.
- The **Variables** tab contains variables in the current context.
- The **Coroutines** tab contains information on running or suspended coroutines. It shows that there are three coroutines. The first one has the **RUNNING** status, and the other two have the **CREATED** status.

Debug the coroutine

3. Resume the debugger session by clicking **Resume Program** in the **Debug** tool window:

Debug the coroutine

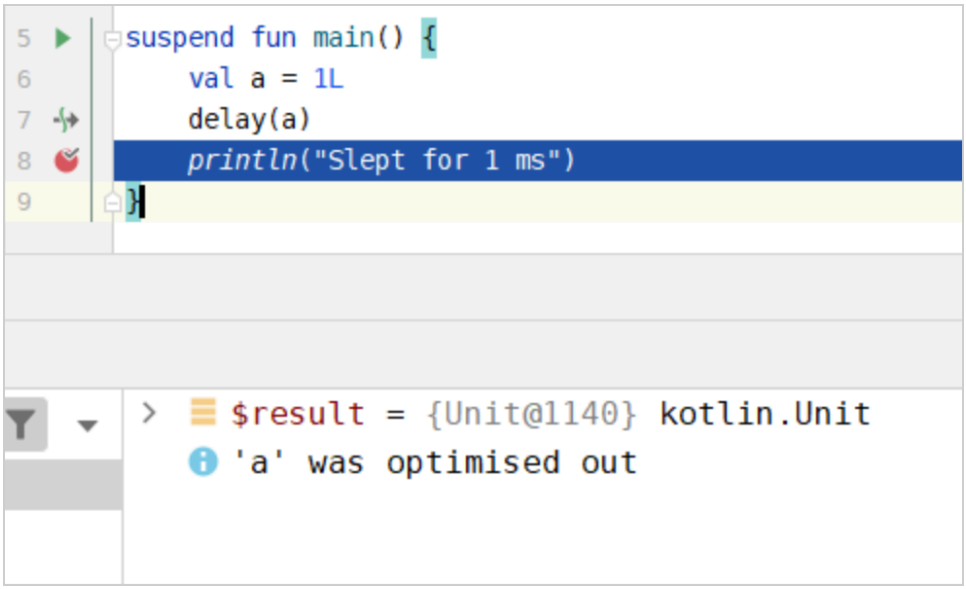
Now the **Coroutines** tab shows the following:

- The first coroutine has the **SUSPENDED** status – it is waiting for the values so it can multiply them.
- The second coroutine is calculating the `a` value – it has the **RUNNING** status.
- The third coroutine has the **CREATED** status and isn't calculating the value of `b`.

4. Resume the debugger session by clicking **Resume Program** in the **Debug** tool window:

Build a console application

Now the **Coroutines** tab shows the following:



- The first coroutine has the **SUSPENDED** status – it is waiting for the values so it can multiply them.
- The second coroutine has computed its value and disappeared.

- The third coroutine is calculating the value of `b` – it has the **RUNNING** status.

Using IntelliJ IDEA debugger, you can dig deeper into each coroutine to debug your code.

Optimized-out variables

If you use `suspend` functions, in the debugger, you might see the "was optimized out" text next to a variable's name:

Variable "a" was optimized out

This text means that the variable's lifetime was decreased, and the variable doesn't exist anymore. It is difficult to debug code with optimized variables because you don't see their values. You can disable this behavior with the `-Xdebug` compiler option.

Never use this flag in production: `-Xdebug` can cause memory leaks.

Debug Kotlin Flow using IntelliJ IDEA – tutorial

This tutorial demonstrates how to create Kotlin Flow and debug it using IntelliJ IDEA.

The tutorial assumes you have prior knowledge of the coroutines and flow concepts.

Create a Kotlin flow

Create a Kotlin flow with a slow emitter and a slow collector:

1. Open a Kotlin project in IntelliJ IDEA. If you don't have a project, create one.
2. To use the `kotlinx.coroutines` library in a Gradle project, add the following dependency to `build.gradle(.kts)`:

Kotlin

```
dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
}
```

Groovy

```
dependencies {
    implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
}
```

For other build systems, see instructions in the `kotlinx.coroutines` README.

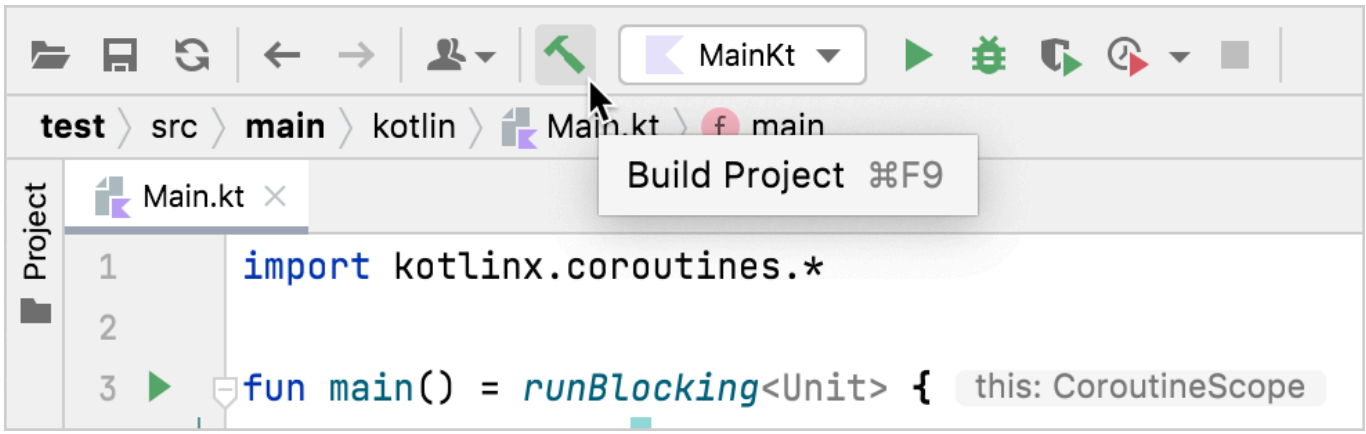
3. Open the `Main.kt` file in `src/main/kotlin`.

   The `src` directory contains Kotlin source files and resources. The `Main.kt` file contains sample code that will print `Hello World!`.

4. Create the `simple()` function that returns a flow of three numbers:

   - Use the `delay()` function to imitate CPU-consuming blocking code. It suspends the coroutine for 100 ms without blocking the thread.
   - Produce the values in the `for` loop using the `emit()` function.

```
import kotlinx.coroutines.*
import kotlinx.coroutines.flow.*
import kotlin.system.*

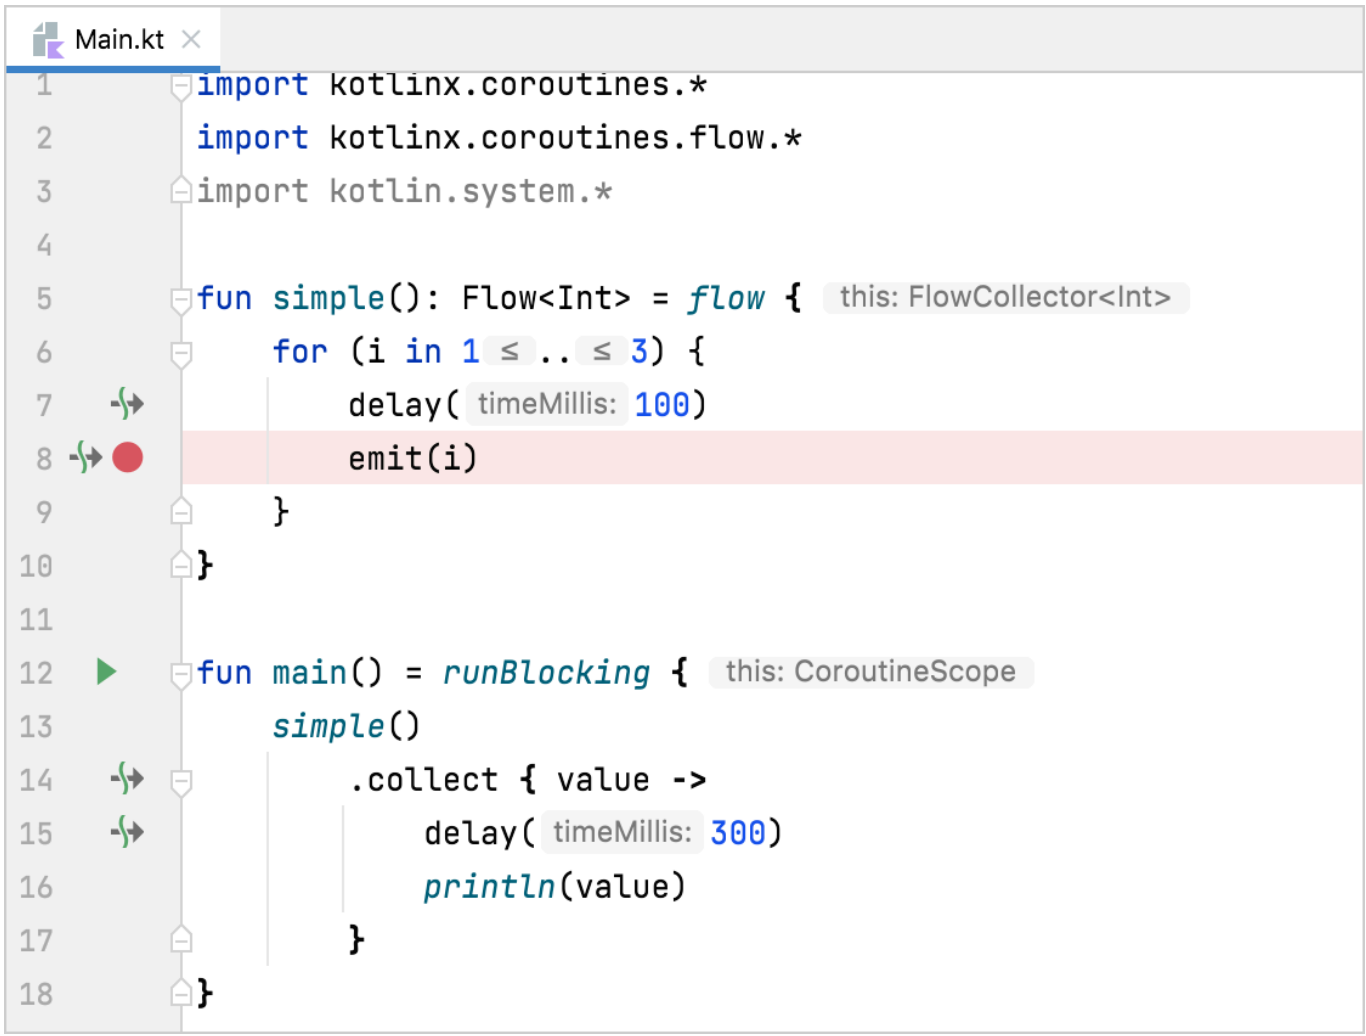


fun simple(): Flow<Int> = flow {
    for (i in 1..3) {
        delay(100)
        emit(i)
    }
}
```

5. Change the code in the `main()` function:

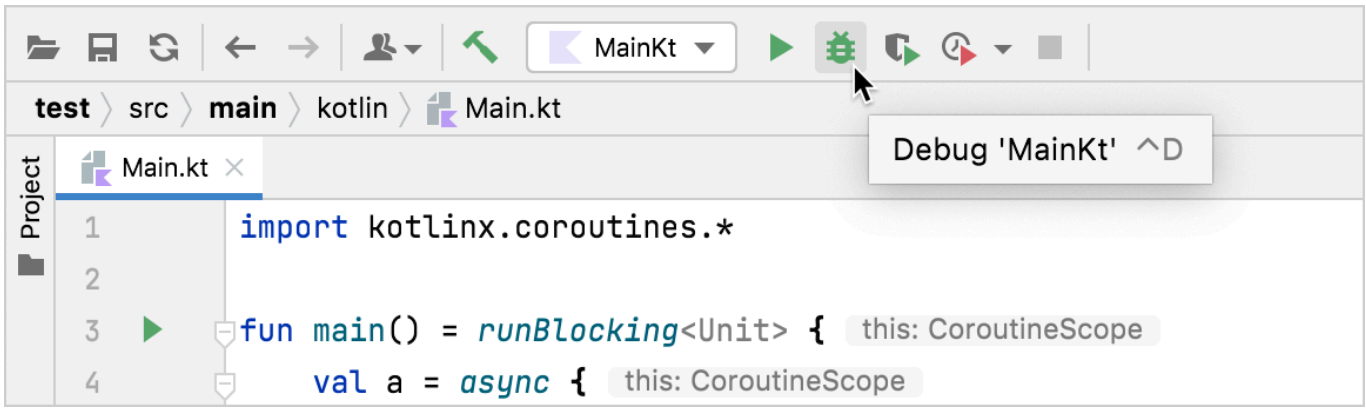
   - Use the `runBlocking()` block to wrap a coroutine.
   - Collect the emitted values using the `collect()` function.
   - Use the `delay()` function to imitate CPU-consuming code. It suspends the coroutine for 300 ms without blocking the thread.
   - Print the collected value from the flow using the `println()` function.

```
fun main() = runBlocking {
    simple()
        .collect { value ->
            delay(300)
            println(value)
        }
}
```



6. Build the code by clicking **Build Project**.

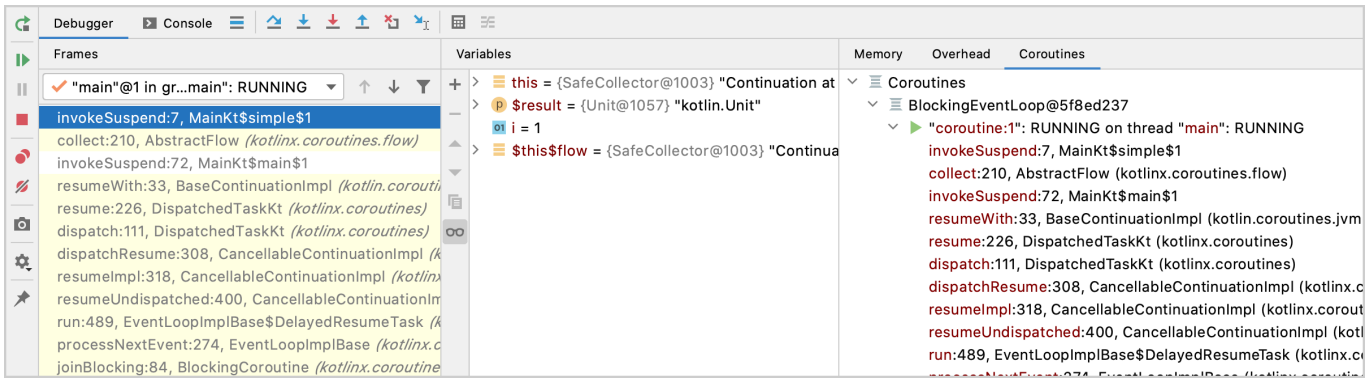
Build an application



Debug the coroutine

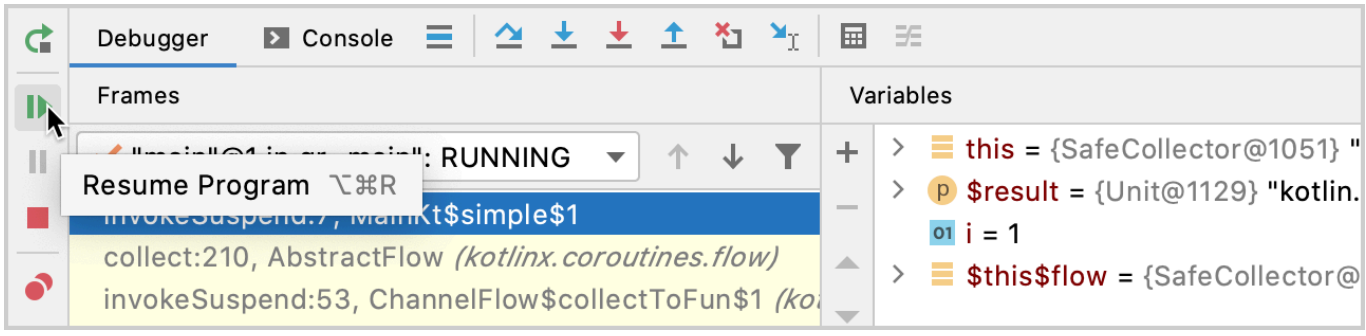
1. Set a breakpoint at the line where the `emit()` function is called:

Build a console application



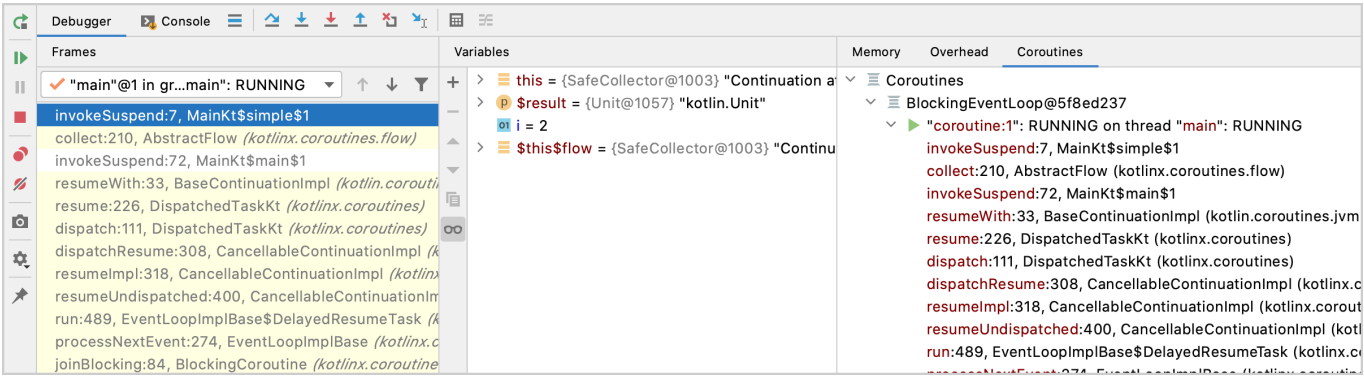
2. Run the code in debug mode by clicking **Debug** next to the run configuration at the top of the screen.

Build a console application



The **Debug** tool window appears:

- The **Frames** tab contains the call stack.
- The **Variables** tab contains variables in the current context. It tells us that the flow is emitting the first value.
- The **Coroutines** tab contains information on running or suspended coroutines.



Debug the coroutine

3. Resume the debugger session by clicking **Resume Program** in the **Debug** tool window. The program stops at the same breakpoint.

Debug the coroutine

Now the flow emits the second value.

Debug the coroutine

Optimized-out variables

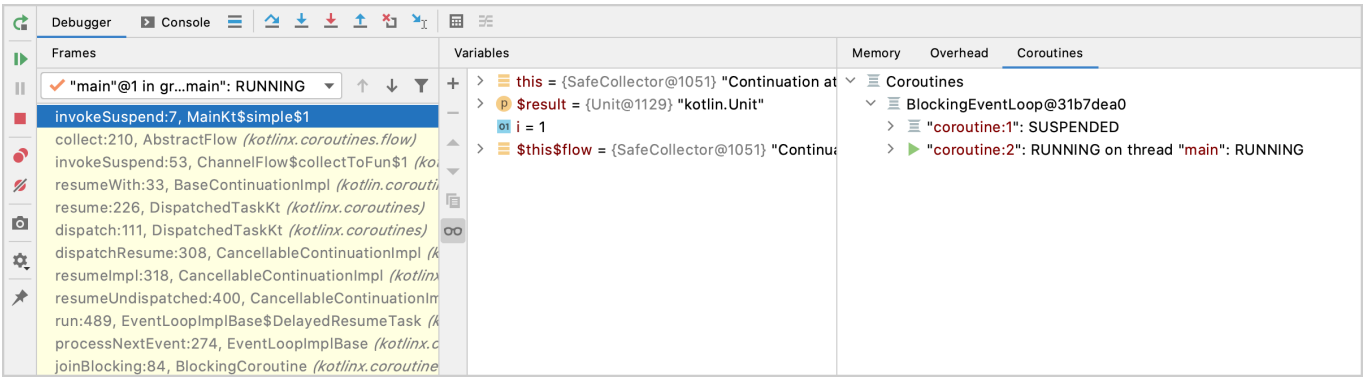
If you use `suspend` functions, in the debugger, you might see the "was optimized out" text next to a variable's name:

Variable "a" was optimized out

This text means that the variable's lifetime was decreased, and the variable doesn't exist anymore. It is difficult to debug code with optimized variables because you don't see their values. You can disable this behavior with the `-Xdebug` compiler option.

Never use this flag in production: `-Xdebug` can cause memory leaks.

Add a concurrently running coroutine



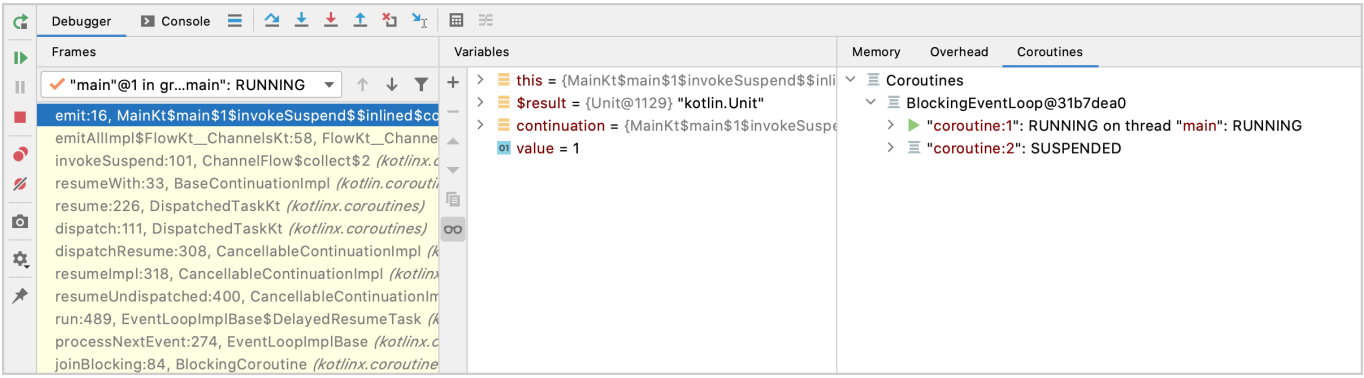
1. Open the `Main.kt` file in `src/main/kotlin`.
2. Enhance the code to run the emitter and collector concurrently:
   - Add a call to the `buffer()` function to run the emitter and collector concurrently. `buffer()` stores emitted values and runs the flow collector in a separate coroutine.

```
fun main() = runBlocking<Unit> {
    simple()
        .buffer()
        .collect { value ->
            delay(300)
            println(value)
        }
}
```

3. Build the code by clicking **Build Project**.

Debug a Kotlin flow with two coroutines

1. Set a new breakpoint at `println(value)`.
2. Run the code in debug mode by clicking **Debug** next to the run configuration at the top of the screen.



Build a console application

The **Debug** tool window appears.

In the **Coroutines** tab, you can see that there are two coroutines running concurrently. The flow collector and emitter run in separate coroutines because of the `buffer()` function. The `buffer()` function buffers emitted values from the flow. The emitter coroutine has the **RUNNING** status, and the collector coroutine has the **SUSPENDED** status.

3. Resume the debugger session by clicking **Resume Program** in the **Debug** tool window.

Debugging coroutines

Now the collector coroutine has the **RUNNING** status, while the emitter coroutine has the **SUSPENDED** status.

You can dig deeper into each coroutine to debug your code.

Serialization

Serialization is the process of converting data used by an application to a format that can be transferred over a network, or stored in a database or a file. Deserialization is the opposite process of converting external data back into a runtime object. Together, they are essential to most applications that exchange data with third parties.

Some data serialization formats, such as JSON and Protocol Buffers, are particularly common. These formats are language-neutral and platform-neutral, so you can use them to exchange data between systems written in any modern language. Kotlin provides this functionality through the `kotlinx.serialization` libraries, which support multiple platforms and data formats.

If you're new to serialization in Kotlin, we recommend starting with the Get Started with Serialization tutorial. It walks you through adding the Kotlin serialization library to your project and shows you how to serialize and deserialize your first class.

Get started with serialization

Kotlin serialization libraries

Kotlin serialization offers support for all platforms, including JVM, JavaScript, and Native. You can use the same dependency declaration regardless of the target platform.

Kotlin serialization supports various serialization formats, such as JSON, CBOR, and Protocol buffers through different serialization format libraries. These libraries build on the core `kotlinx.serialization` library. For the complete list of supported serialization formats, see Supported serialization formats.

All Kotlin serialization format libraries are part of the `org.jetbrains.kotlinx:` group, with names starting with `kotlinx-serialization-` and suffixes that reflect the serialization format. For example:

- `org.jetbrains.kotlinx:kotlinx-serialization-json` provides JSON serialization.
- `org.jetbrains.kotlinx:kotlinx-serialization-cbor` provides CBOR serialization.

The `kotlinx.serialization` libraries follow their own versioning, independent of Kotlin. You can find the latest release versions on GitHub.

> When you're not using a specific format library, for example, when you're writing your own serialization format, use the `kotlinx-serialization-core` library as the dependency.

Supported serialization formats

`kotlinx.serialization` includes serialization format libraries for various formats:

Format	Artifact ID	Platform	Status
JSON	`kotlinx-serialization-json`	All supported platforms	Stable
HOCON	`kotlinx-serialization-hocon`	JVM only	Experimental
Protocol Buffers	`kotlinx-serialization-protobuf`	All supported platforms	Experimental
CBOR	`kotlinx-serialization-cbor`	All supported platforms	Experimental
Properties	`kotlinx-serialization-properties`	All supported platforms	Experimental

All serialization format libraries, except for the JSON serialization library (`kotlinx-serialization-json`), are Experimental. Their APIs might change at any time. For more details about JSON serialization, see JSON serialization overview.

There are also community-maintained libraries that support more serialization formats, such as YAML or Apache Avro.

You can find out more about experimental serialization formats in Alternative and custom formats.

Supported serialization types

Kotlin serialization supports a variety of built-in types, including all primitive types and most composite types from the Kotlin standard library like the `List` type. For more information, see Serialize built-in types.

Additionally, classes annotated with `@Serializable` are fully supported for serialization, enabling the conversion of class instances to and from formats like JSON. For more information, see Serialize classes.

What's next

- Learn the basics of Kotlin serialization in the Get started with serialization tutorial.
- See how the Kotlin serialization library processes primitives, collections, and other built-in types
- Explore more complex JSON serialization scenarios in the JSON serialization overview.
- Dive into Serialize classes to learn how to serialize classes and modify the default behavior of the `@Serializable` annotation.

- Learn how to obtain generated serializers, create custom serializers, and apply serializers in Create and use serializers.
- See how to serialize different types through a shared base type in Serialize polymorphic classes.
- Explore experimental serialization formats, including CBOR, ProtoBuf, and Properties, and learn how to create custom formats in Alternative and custom formats.

Get started with Kotlin serialization

Serialization converts objects into a format you can store or transmit and later reconstruct.

Kotlin serialization supports multiple formats. This tutorial shows you how to add the necessary plugins and dependencies for Kotlin serialization, and how to serialize and deserialize objects in JSON format.

Add plugins and dependencies

To include the `kotlinx.serialization` library in your project, add the corresponding plugin and dependency configuration based on your build tool:

Gradle Kotlin

```
// build.gradle.kts
plugins {
    kotlin("plugin.serialization") version "2.4.20"
}

dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-serialization-json:1.11.0")
}
```

Gradle Groovy

```
// build.gradle
plugins {
    id 'org.jetbrains.kotlin.plugin.serialization' version '2.4.20'
}

dependencies {
    implementation 'org.jetbrains.kotlinx:kotlinx-serialization-json:1.11.0'
}
```

Maven

```
<!-- pom.xml -->
<properties>
    <kotlin.version>2.4.20</kotlin.version>
    <serialization.version>1.11.0</serialization.version>
</properties>

<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>${kotlin.version}</version>
            <executions>
                <execution>
                    <id>compile</id>
                    <phase>compile</phase>
                    <goals>
                        <goal>compile</goal>
                    </goals>
                </execution>
            </executions>
            <configuration>
                <compilerPlugins>
                    <plugin>kotlinx-serialization</plugin>
                </compilerPlugins>
            </configuration>
            <dependencies>
                <dependency>
                    <groupId>org.jetbrains.kotlin</groupId>
                    <artifactId>kotlin-maven-serialization</artifactId>
                    <version>${kotlin.version}</version>
                </dependency>
            </dependencies>
        </plugin>
    </plugins>
</build>

<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-serialization-json</artifactId>
        <version>${serialization.version}</version>
    </dependency>
</dependencies>
```

To set up the Kotlin compiler plugin for Bazel, follow the example from the rules_kotlin repository. Bazel isn't officially supported by the Kotlin team, and this repository is maintained independently.

Add the library to a multiplatform project

To use Kotlin serialization for JSON in multiplatform projects, add the JSON serialization library dependency to your common source set:

```
commonMain {
   dependencies {
      implementation("org.jetbrains.kotlinx:kotlinx-serialization-json:1.11.0")
   }
}
```

This dependency automatically includes the core serialization library as well.

Configure R8 for Kotlin serialization in Android projects

The Kotlin serialization library includes default ProGuard rules, so you don't need additional setup to keep serializers for all serializable classes after shrinking. However, these rules don't apply to classes with named companion objects.

To retain serializers for classes with named companion objects, add rules based on the compatibility mode you use to your `proguard-rules.pro` file:

R8 compatibility mode

```
# Serializer for classes with named companion objects are retrieved using getDeclaredClasses
# If you have any such classes, replace the examples below with your own
-keepattributes InnerClasses # Required for getDeclaredClasses

-if @kotlinx.serialization.Serializable class
com.example.myapplication.HasNamedCompanion, # <-- List serializable classes with named companions
com.example.myapplication.HasNamedCompanion2
{
    static **$* *;
}
-keepnames class <1>$$serializer { # Using -keepnames is enough for the serializer() call to reference
the class correctly
    static <1>$$serializer INSTANCE;
}
```

R8 full mode

```
# Serializer for classes with named companion objects are retrieved using getDeclaredClasses
# If you have any such classes, replace the examples below with your own
-keepattributes InnerClasses # Required for getDeclaredClasses

-if @kotlinx.serialization.Serializable class
com.example.myapplication.HasNamedCompanion, # <-- List serializable classes with named companions
com.example.myapplication.HasNamedCompanion2
{
    static **$* *;
}
-keepnames class <1>$$serializer { # Using -keepnames is enough for the serializer() call to reference
the class correctly
    static <1>$$serializer INSTANCE;
}

# Keep both serializer and serializable classes to save the attribute InnerClasses
-keepclasseswithmembers, allowshrinking, allowobfuscation, allowaccessmodification class
com.example.myapplication.HasNamedCompanion, # <-- List serializable classes with named companions
com.example.myapplication.HasNamedCompanion2
{
    *;
}
```

You can exclude serializable classes that are never serialized at runtime by using custom ProGuard rules with narrower class specifications.

Serialize objects to JSON

In Kotlin, you can serialize objects to JSON using the `kotlinx.serialization` library.

To make a class serializable, you need to mark it with the `@Serializable` annotation. This annotation instructs the compiler to generate the code required for serializing and deserializing instances of the class. For more information, see The `@Serializable` annotation.

Let's look at an example:

1. Import declarations from the necessary serialization libraries:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
```

2. Make a class serializable by annotating it with `@Serializable`:

```
@Serializable
data class Book(val yearPublished: Int, val title: String)
```

> The `@Serializable` annotation enables default serialization of all properties with backing fields. You can customize serialization behavior with property-level annotations, optional properties, and more.
>
> For more information, see Serialize classes.

3. Use the `Json.encodeToString()` function to serialize an instance of this class:

```
// Imports declarations from the serialization and JSON handling libraries
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Marks the Book class as serializable
@Serializable
data class Book(val yearPublished: Int, val title: String)

fun main() {
    // Serializes an instance of the Book class into a JSON string
    val json = Json.encodeToString(Book(1937, "The Hobbit"))
    println(json)
    // {"yearPublished":1937,"title":"The Hobbit"}
}
```

As a result, you get a string containing the state of this object in JSON format:
`{"yearPublished":1937,"title":"The Hobbit"}`

You can also serialize a collection of objects in a single call:

```
val bookList = listOf(Book(1937, "The Hobbit"), Book(1867, "War and Peace"))
val jsonList = Json.encodeToString(bookList)
```

Deserialize objects from JSON

Deserialization converts a JSON string back into an object.

To deserialize an object from JSON in Kotlin:

1. Import declarations from the necessary serialization libraries:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
```

2. Make a class serializable by annotating it with `@Serializable`:

```
@Serializable
data class Book(val yearPublished: Int, val title: String)
```

3. Use the `Json.decodeFromString()` function to deserialize an object from JSON:

```
// Imports declarations from the serialization and JSON handling libraries
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Marks the Book class as serializable
@Serializable
data class Book(val yearPublished: Int, val title: String)

fun main() {
    // Deserializes a JSON string into an instance of the Book class
    val obj = Json.decodeFromString<Book>("""{"yearPublished":1937, "title": "The Hobbit"}""")
    println(obj)
    // Book(yearPublished=1937, title=The Hobbit)
}
```

Congratulations! You have successfully serialized an object to JSON and deserialized it back into an object in Kotlin.

What's next

- Learn how to serialize basic types such as primitives and strings, as well as certain standard library classes, in Serialize built-in types.
- Discover how to customize class serialization and adjust the default behavior of the `@Serializable` annotation in Serialize classes.
- Dive deeper into handling JSON data and configuring JSON serialization in the JSON serialization overview.

Serialize built-in types

The Kotlin serialization library supports a variety of built-in types, including basic types such as primitives and strings, as well as certain standard library classes. The following sections describe these types in detail and show how to serialize them.

Basic types

Kotlin serialization provides built-in serializers for types that are represented as a single value in serialized data. This includes primitives, strings, and enums.

For example, here's how you can serialize a `Long` type:

```
// Imports the necessary library declarations
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Data(val signature: Long)

fun main() {
    val data = Data(0x1CAFE2FEED0BABE0)
    println(Json.encodeToString(data))
    // {"signature":2067120338512882656}
}
```

Numbers

You can serialize all Kotlin number types, including integers and floating-point numbers, using their natural JSON representations:

```kotlin
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlin.math.PI

@Serializable
class Data(
    val answer: Int,
    val pi: Double
)

fun main() {
    val data = Data(42, PI)
    println(Json.encodeToString(data))
    // {"answer":42,"pi":3.141592653589793}
}
```

Unsigned numbers

Kotlin serialization supports Kotlin's unsigned integer types like `UByte` and `UInt`. In JSON, these values are serialized as regular JSON numbers and preserve their full unsigned range:

```kotlin
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Counter(val counted: UByte, val description: String)

fun main() {
    val counted = 239.toUByte()
    println(Json.encodeToString(Counter(counted, "tries")))
    // {"counted":239,"description":"tries"}
}
```

Although JSON preserves the full range of unsigned numbers, other serialization formats may handle them differently. For example, ProtoBuf and CBOR serialize these types using their signed counterparts.

`Long` numbers as strings

You can represent `Long` numbers as strings in JSON. This is useful in JavaScript environments, where JavaScript's `Number` type can't precisely represent all Kotlin `Long` values, which may lead to precision loss.

Use `LongAsStringSerializer` with the `@Serializable` annotation to encode `Long` values as strings in JSON:

```
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*

@Serializable
class Data(
    @Serializable(LongAsStringSerializer::class)
    val signature: Long
)

fun main() {
    val data = Data(0x1CAFE2FEED0BABE0)
    println(Json.encodeToString(data))
    // {"signature":"2067120338512882656"}
}
```

You can also specify serializers like `LongAsStringSerializer` for all properties in a file. For more information, see Specify serializers for a file.

Enum classes

All `enum` classes are serializable by default without the `@Serializable` annotation. When serialized in JSON, an `enum` is encoded as a string:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// The @Serializable annotation isn't required for enum classes
enum class Status { SUPPORTED }

@Serializable
class Project(val name: String, val status: Status)

fun main() {
    val data = Project("kotlinx.serialization", Status.SUPPORTED)
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","status":"SUPPORTED"}
}
```

When targeting Kotlin/JS or Kotlin/Native, you must use the `@Serializable` annotation for an `enum` class to use it as a root object, such as in `encodeToString<Status>(Status.SUPPORTED)`.

Customize serial names of enum entries

To customize the serial names of enum entries, use the `@SerialName` annotation and mark the enum class with `@Serializable`:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Requires the @Serializable annotation because of @SerialName
@Serializable
enum class Status { @SerialName("maintained") SUPPORTED }

@Serializable
class Project(val name: String, val status: Status)

fun main() {
    val data = Project("kotlinx.serialization", Status.SUPPORTED)
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","status":"maintained"}
}
```

For more information on customizing serial names, see Customize serial names.

Standard library types

Kotlin serialization supports several types from the standard library, but some classes, such as ranges and the `Regex` class, aren't supported.

Pair and triple

You can serialize the `Pair` and `Triple` classes from the Kotlin standard library:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String)

fun main() {
    val pair = 1 to Project("kotlinx.serialization")
    println(Json.encodeToString(pair))
    // {"first":1,"second":{"name":"kotlinx.serialization"}}
}
```

Collections

Kotlin serialization supports collection types, including both read-only and mutable variants of `List`, `Set`, and `Map`. It also supports their concrete implementations such as `ArrayList` and `LinkedHashSet`, as well as generic and primitive array types. The way these collections are represented depends on the serialization format.

In JSON, lists and sets are serialized as JSON arrays, and maps are represented as JSON objects.

Kotlin uses the declared type to deserialize JSON. During deserialization, the type of the resulting object is determined by the static type specified in the source code. This type can be either the type of the property or the type parameter of the decoding function.

Serialize lists

Kotlin serialization serializes `List` types as JSON arrays. Here's an example with a list of classes:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String)

fun main() {
    val list = listOf(
        Project("kotlinx.serialization"),
        Project("kotlinx.coroutines")
    )
    println(Json.encodeToString(list))
    // [{"name":"kotlinx.serialization"},{"name":"kotlinx.coroutines"}]
}
```

Serialize sets

`Set` types are serialized as JSON arrays, just like `List` types:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String)

fun main() {
    val set = setOf(
        Project("kotlinx.serialization"),
        Project("kotlinx.coroutines")
    )
    println(Json.encodeToString(set))
    // [{"name":"kotlinx.serialization"},{"name":"kotlinx.coroutines"}]
}
```

By default, you can deserialize sets with duplicate entries. The behavior for handling duplicates is implementation-defined.

Serialize maps

Kotlin serialization supports `Map` types with primitive or enum keys:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String)

fun main() {
    // Creates a map with Int keys
    val map = mapOf(
        1 to Project("kotlinx.serialization"),
        2 to Project("kotlinx.coroutines")
    )
    println(Json.encodeToString(map))
    // {"1":{"name":"kotlinx.serialization"},"2":{"name":"kotlinx.coroutines"}}
}
```

Map serialization depends on the format. In JSON, maps are represented as objects. Since JSON object keys are always strings, keys are encoded as strings even if they are numbers in Kotlin. Other formats, such as CBOR, support maps with non-primitive keys and preserve them as such.

> JSON doesn't natively support complex or composite keys. To encode structured objects as map keys, see Allow structured map keys.

Deserialization behavior of collections

Kotlin uses the declared type to deserialize JSON. For example, with collections, a `List` preserves duplicates, while a `Set` enforces uniqueness:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class Data(
    val a: List<Int>,
    val b: Set<Int>
)

fun main() {
    val data = Json.decodeFromString<Data>("""
        {
            "a": [42, 42],
            "b": [42, 42]
        }
    """)
    // Duplicates are removed from data.b because the Set type enforces unique elements
    println(data)
    // Data(a=[42, 42], b=[42])
}
```

> For more information about collections in Kotlin, see Collections overview.

Unit and singleton objects

Kotlin's `Unit` type and other singleton objects are serializable. A singleton is a class with only one instance, where the state is defined by the object itself rather than by external properties. In JSON, singleton objects are serialized as empty structures:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
object SerializationVersion {
    val libraryVersion: String = "1.0.0"
}

fun main() {
    println(Json.encodeToString(SerializationVersion))
    // {}
    println(Json.encodeToString(Unit))
    // {}
}
```

You can use serialized singleton objects in closed polymorphic hierarchies to represent cases without additional fields.

Duration and Instant

Kotlin's `Duration` type is serialized to a string using the ISO-8601-2 format:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlin.time.*

fun main() {
    val duration = 1000.toDuration(DurationUnit.SECONDS)
    println(Json.encodeToString(duration))
    // "PT16M40S"
}
```

You can also serialize Kotlin's `Instant` type as a string representing a point in time using the ISO-8601-1 format:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlin.time.*

fun main() {
    val instant = Instant.fromEpochMilliseconds(1607505416124)
    println(Json.encodeToString(instant))
    // "2020-12-09T09:16:56.124Z"
}
```

Nothing

The `Nothing` type is serializable by default. It has no instances, so encoding or decoding it throws an exception. Use `Nothing` when a type is syntactically required, but not involved in serialization, like in a polymorphic hierarchy with a generic base type:

```
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*

@Serializable
sealed class ParametrizedParent<out R> {
    @Serializable
    data class ChildWithoutParameter(val value: Int) : ParametrizedParent<Nothing>()
}

fun main() {
    println(Json.encodeToString(ParametrizedParent.ChildWithoutParameter(42)))
    // {"value":42}
}
```

What's next

- Dive into Serialize classes to learn how to serialize classes and how to modify the default behavior of the `@Serializable` annotation.

- To explore more complex JSON serialization scenarios, see JSON serialization overview.
- Learn more about polymorphism and serializing different types through a shared base in Serialize polymorphic classes.

Serialize classes

The `@Serializable` annotation enables the default serialization of all class properties with backing fields. You can customize this behavior to fit your specific needs. This page covers various serialization techniques, showing you how to specify which properties are serialized, and how the serialization process is managed.

Before starting, make sure you've imported the necessary library dependencies.

The @Serializable annotation

The `@Serializable` annotation enables the automatic serialization of class properties, allowing a class to be converted to and from formats such as JSON.

In Kotlin, only properties with backing fields are serialized:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(
    // Property with a backing field - serialized
    var name: String
) {
    // Property with a backing field - serialized
    var stars: Int = 0

    // Getter-only property without a backing field - not serialized
    val path: String
        get() = "kotlin/$name"

    // Delegated property - not serialized
    var id by ::name
}

fun main() {
    val data = Project("kotlinx.serialization").apply { stars = 9000 }
    // Prints only the name and the stars properties
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","stars":9000}
}
```

Serialize class references

Classes annotated with `@Serializable` can contain properties that reference other classes. The referenced classes must also be annotated with `@Serializable`. When encoded to JSON, this results in a nested JSON object:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
// The owner property references another serializable class User
class Project(val name: String, val owner: User)

// The referenced class must also be annotated with @Serializable
@Serializable
class User(val name: String)

fun main() {
    val owner = User("kotlin")
    val data = Project("kotlinx.serialization", owner)
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","owner":{"name":"kotlin"}}
}
```

To reference non-serializable classes, annotate the corresponding properties with `@Transient`, or provide a custom serializer for them.

Serialization of repeated object references

Kotlin serialization is designed to encode and decode plain data. It doesn't support reconstruction of arbitrary object graphs with repeated object references. For example, when serializing an object that references the same instance twice, it's encoded twice:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String, val owner: User, val maintainer: User)

@Serializable
class User(val name: String)

fun main() {
    val owner = User("kotlin")
    // References owner twice
    val data = Project("kotlinx.serialization", owner, owner)
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","owner":{"name":"kotlin"},"maintainer":{"name":"kotlin"}}
}
```

If you attempt to serialize a circular structure, it results in stack overflow. To exclude references from serialization, use the @Transient annotation.

Serialize generic classes

Generic classes in Kotlin support type-polymorphism, which is enforced by Kotlin serialization at compile-time. For example, consider a generic serializable class `Payload<T>`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
// The Payload<T> class can be used with built-in types like Int
// or with @Serializable user-defined types like Repository
class Payload<T>(val value: T)

@Serializable
data class Repository(val name: String, val language: String)

@Serializable
class BackupData(
    val issueCount: Payload<Int>,
    val mainRepo: Payload<Repository>
)

fun main() {
    val backup = BackupData(
        Payload(42),
        Payload(Repository("kotlinx.serialization", "Kotlin"))
    )
    println(Json.encodeToString(backup))
    // {"issueCount":{"value":42},"mainRepo":{"value":
{"name":"kotlinx.serialization","language":"Kotlin"}}}
}
```

When you serialize a generic class like `Box<T>`, the JSON output depends on the actual type you specify for `T` at compile time. If that type isn't serializable, you get a compile-time error.

Optional properties

Properties with *default values* are optional during deserialization and can be skipped during serialization, if the format is configured to do so. For example, the default JSON configuration skips encoding default values.

Set default values for optional properties

In Kotlin, an object can be deserialized only when all its properties are present in the input. To make a property optional for serialization, set a default value that's used when no value is provided in the input:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
// Sets a default value for the optional language property
data class Project(val name: String, val language: String = "Kotlin")

fun main() {
    val data = Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization"}
    """)
    println(data)
    // Project(name=kotlinx.serialization, language=Kotlin)
}
```

Serialize nullable properties

Kotlin serialization natively supports nullable properties. Like other default values, `null` values aren't encoded in the JSON output:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
// Defines a class with the renamedTo nullable property that has a null default value
class Project(val name: String, val renamedTo: String? = null)

fun main() {
    val data = Project("kotlinx.serialization")
    // The renamedTo property isn't encoded because its value is null
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization"}
}
```

Additionally, Kotlin's null safety is strongly enforced during deserialization. If a JSON object contains a `null` value for a non-nullable property, an exception is thrown even when the property has a default value:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class Project(val name: String, val language: String = "Kotlin")

fun main() {
    val data = Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","language":null}
    """)
    println(data)
    // JsonDecodingException
}
```

If you need to handle `null` values from third-party JSON, you can coerce them to a default value.

You can also omit explicit `null` values from the encoded JSON with the `explicitNulls` property.

Initializers in optional properties

When the serialization input includes a value for an optional property, the property's initializer isn't called. For this reason, avoid using code with side effects in property initializers.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

fun computeLanguage(): String {
    println("Computing")
    return "Kotlin"
}

@Serializable
// Skips the initializer if language is in the input
data class Project(val name: String, val language: String = computeLanguage())

fun main() {
    val data = Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","language":"Java"}
    """)
    println(data)
    // Project(name=kotlinx.serialization, language=Java)
}
```

In this example, since the `language` property is specified in the input, the `Computing` string isn't printed in the output.

Manage the serialization of default properties with `@EncodeDefault`

By default, JSON serialization excludes properties that have default values. This reduces the size of the serialized data and avoids unnecessary visual clutter.

Here's an example where the `language` property is excluded from the output because its value equals the default:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class Project(val name: String, val language: String = "Kotlin")

fun main() {
    val data = Project("kotlinx.serialization")
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization"}
}
```

You can configure a `Json` instance to encode default values for all properties by default.

To always serialize a property, regardless of its value or format settings, use the `@EncodeDefault` annotation. Alternatively, you can set the `EncodeDefault.Mode` parameter to change this behavior.

Let's look at an example where the `language` property is always included in the serialized output, while the `projects` property is excluded when it's an empty list:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.EncodeDefault.Mode.NEVER

@Serializable
data class Project(
    val name: String,
    // Always includes the language property in the serialized output
    // even if it has the default value "Kotlin"
    @EncodeDefault val language: String = "Kotlin"
)

@Serializable
data class User(
    val name: String,
    // Excludes projects when it's an empty list, even if it has a default value
    @EncodeDefault(NEVER) val projects: List<Project> = emptyList()
)

fun main() {
    val adminUser = User("Alice", listOf(Project("kotlinx.serialization")))
    val guestUser = User("Bob")
    // Serializes projects because it contains a value
    // language is always serialized
    println(Json.encodeToString(adminUser))
    // {"name":"Alice","projects":[{"name":"kotlinx.serialization","language":"Kotlin"}]}

    // Excludes projects because it's an empty list
    // and EncodeDefault.Mode is set to NEVER, so it's not serialized
    println(Json.encodeToString(guestUser))
    // {"name":"Bob"}
}
```

Make properties required with the `@Required` annotation

Annotate a property with `@Required` to make it required in the input. This enforces that the input contains the property, even if it has a default value:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.Required

@Serializable
// Marks the language property as required
data class Project(val name: String, @Required val language: String = "Kotlin")

fun main() {
    val data = Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization"}
    """)
    println(data)
    // MissingFieldException
}
```

Customize class serialization

Kotlin serialization provides several ways to modify how classes are serialized. This section covers techniques for customizing property names, controlling property inclusion, and more.

Customize serial names

By default, property names in the serialization output, such as JSON, match their names in the source code.

You can customize these names, called *serial names*, with the `@SerialName` annotation. Use it to make a property name more descriptive in the serialized output:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
// Changes the lang property to language using @SerialName
class Project(val name: String, @SerialName("language") val lang: String)

fun main() {
    val data = Project("kotlinx.serialization", "Kotlin")
    // Prints the more descriptive property name in the JSON output
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","language":"Kotlin"}
}
```

Define constructor properties for serialization

A class annotated with `@Serializable` must declare all parameters in its primary constructor as properties.

If you need to perform additional initialization logic before assigning values to properties, use a secondary constructor. The primary constructor can remain `private` and handle property initialization.

Here's an example where the secondary constructor parses a string into two values, which are then passed to the primary constructor for serialization:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project private constructor(val owner: String, val name: String) {
    // Creates a Project object using a path string
    constructor(path: String) : this(
        owner = path.substringBefore('/'),
        name = path.substringAfter('/')
    )

    val path: String
        get() = "$owner/$name"
}
fun main() {
    println(Json.encodeToString(Project("kotlin/kotlinx.serialization")))
    // {"owner":"kotlin","name":"kotlinx.serialization"}
}
```

Validate data in the primary constructor

After deserialization, the `kotlinx.serialization` plugin runs the class's initializer blocks, just like when you create an instance. This allows you to validate constructor parameters and reject invalid data during deserialization.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String) {
    // Validates that the name is not empty
    init {
        require(name.isNotEmpty()) { "name cannot be empty" }
    }
}

fun main() {
    val data = Json.decodeFromString<Project>("""
        {"name":""}
    """)
    println(data)
    // Exception in thread "main" java.lang.IllegalArgumentException: name cannot be empty
}
```

Exclude properties with the `@Transient` annotation

You can exclude a property from serialization with the `@Transient` annotation. Transient properties must have a default value.

If you explicitly specify a value for a transient property in the input, even if it matches the default value, a `JsonDecodingException` is thrown:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.Transient
import kotlinx.serialization.json.*

@Serializable
// Excludes the language property from serialization
data class Project(val name: String, @Transient val language: String = "Kotlin")

fun main() {
    // Throws an exception even though input matches the default value
    val data = Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","language":"Kotlin"}
    """)
    println(data)
    // JsonDecodingException
}
```

> To avoid exceptions from unknown keys in JSON, including those marked with the `@Transient` annotation, enable the `ignoreUnknownKeys` configuration property. For more information, see the Ignore unknown keys section.

What's next

- Explore more complex JSON serialization scenarios in the JSON serialization overview.
- Learn how to obtain generated serializers, create custom serializers, and apply serializers in Create and use serializers.

JSON serialization overview

The Kotlin serialization library allows you to easily convert Kotlin objects to JSON and back. The `Json` class is the primary tool for this, offering flexibility in how JSON is generated and parsed. You can configure `Json` instances to handle specific JSON behaviors or use its default instance for basic tasks.

With the `Json` class, you can:

- Serialize Kotlin objects to JSON strings using the `encodeToString()` function.
- Deserialize JSON strings back to Kotlin objects with the `decodeFromString()` function.
- Work directly with the `JsonElement` when handling complex JSON structures using the `encodeToJsonElement()` and the `decodeFromJsonElement()` functions.
- Use Experimental extension functions to serialize and deserialize I/O sources without creating intermediate strings, including JVM streams as well as `kotlinx-io` and Okio types.

Before you start, import the following declarations from the serialization library:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
```

Here's a simple example that uses the default `Json` instance to show how JSON serialization works in Kotlin:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class User(val name: String, val age: Int)

fun main() {
    // Uses the default Json instance
    val json = Json

    // Creates a User object
    val user = User("Alice", 30)

    // Converts the User object to a JSON string
    val jsonString = json.encodeToString(user)
    println(jsonString)
    // {"name":"Alice","age":30}

    // Converts the JSON string back to a User object
    val deserializedUser = json.decodeFromString<User>(jsonString)
    println(deserializedUser)
    // User(name=Alice, age=30)
}
```

In addition to using the default configuration, you can customize the `Json` instance for specific use cases, such as ignoring unknown keys:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class Project(val name: String)

// Configures a Json instance to ignore unknown keys
val customJson = Json {
    ignoreUnknownKeys = true
}

fun main() {
    val data = customJson.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","language":"Kotlin"}
    """)
    println(data)
    // Project(name=kotlinx.serialization)
}
```

What's next

- Learn how to customize `Json` instances to address different use cases for serialization and deserialization.
- Explore advanced JSON element handling to manipulate and work with JSON data before it is parsed or serialized.
- Discover how to transform JSON during serialization and deserialization for more control over your data.

Customize the Json instance

The default `Json` instance strictly follows the JSON specification and the declarations in Kotlin classes.

You can use more flexible JSON features or type conversions by creating a custom `Json` instance with the `Json()` builder function:

```
// Creates a Json instance based on the default configuration, allowing special floating-point values
val customJson = Json {
    allowSpecialFloatingPointValues = true
}

// Use the customJson instance with the same syntax as the default one to encode a string
val jsonString = customJson.encodeToString(Data(Double.NaN))
println(jsonString)
```

`Json` instances created this way are immutable and thread-safe, which makes them safe to store in a top-level property for reuse.

> Reusing custom `Json` instances improves performance by allowing them to cache class-specific information.

You can also base a new `Json` instance on an existing one and modify its settings using the same builder syntax:

```
// Creates a new instance based on an existing Json
val lenientJson = Json(customJson) {
    isLenient = true
    prettyPrint = true
}
```

Customize JSON structure

You can customize how a `Json` instance structures data during encoding and decoding. This allows you to control which values appear in the output and how specific types are represented.

Encode default values

By default, the JSON encoder omits default property values because they are automatically applied to missing properties during decoding. This behavior is especially useful for nullable properties with null defaults, as it avoids writing unnecessary `null` values. For more details, see the Manage serialization of default properties section.

To change this default behavior, set the `encodeDefaults` property to `true` in a `Json` instance:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to encode default values
val format = Json { encodeDefaults = true }

@Serializable
class Project(
    val name: String,
    val language: String = "Kotlin",
    val website: String? = null
)

fun main() {
    val data = Project("kotlinx.serialization")

    // Encodes all the property values, including the default ones
    println(format.encodeToString(data))
    // {"name":"kotlinx.serialization","language":"Kotlin","website":null}
}
```

Omit explicit nulls

By default, all `null` values are encoded into JSON output. To omit `null` values, set the `explicitNulls` property to `false` in a `Json` instance:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to omit null values during serialization
val format = Json { explicitNulls = false }

@Serializable
data class Project(
    val name: String,
    val language: String,
    val version: String? = "1.2.2",
    val website: String?,
    val description: String? = null
)

fun main() {
    val data = Project("kotlinx.serialization", "Kotlin", null, null, null)
    val json = format.encodeToString(data)

    // Omits version, website, and description properties from the JSON output
    println(json)
    // {"name":"kotlinx.serialization","language":"Kotlin"}

    // Treats missing nullable properties without defaults as null
    // Fills properties that have defaults with their default values
    println(format.decodeFromString<Project>(json))
    // Project(name=kotlinx.serialization, language=Kotlin, version=1.2.2, website=null,
description=null)
}
```

When `explicitNulls` is set to `false`, encoding and decoding can become asymmetrical. In this example, the `version` property is `null` before encoding, but it decodes to `1.2.2`.

> You can configure the decoder to handle certain invalid input values by treating them as missing properties with the `coerceInputValues` property. For more information, see the Coerce input values section.

Allow structured map keys

The JSON format doesn't natively support maps with structured keys, because JSON keys are strings that represent only primitives or enums. To serialize and deserialize maps with user-defined class keys, use the `allowStructuredMapKeys` property:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to encode maps with structured keys
val format = Json { allowStructuredMapKeys = true }

@Serializable
data class Project(val name: String)

fun main() {
    val map = mapOf(
        Project("kotlinx.serialization") to "Serialization",
        Project("kotlinx.coroutines") to "Coroutines"
    )
    // Serializes the map with structured keys as a JSON array:
    // [key1, value1, key2, value2,...]
    println(format.encodeToString(map))
    // [{"name":"kotlinx.serialization"},"Serialization",{"name":"kotlinx.coroutines"},"Coroutines"]
}
```

Allow special floating-point values

By default, special floating-point values like `Double.NaN` and infinities aren't supported in JSON because the JSON specification prohibits them.

To enable their encoding and decoding, set the `allowSpecialFloatingPointValues` property to `true` in a `Json` instance:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to allow special floating-point values
val format = Json { allowSpecialFloatingPointValues = true }

@Serializable
class Data(
    val value: Double
)

fun main() {
    val data = Data(Double.NaN)
    // Produces a non-standard JSON output used for representing special floating-point values
    println(format.encodeToString(data))
    // {"value":NaN}
}
```

Specify class discriminator for polymorphism

When working with polymorphic data, you can use the `classDiscriminator` property to specify a key name that identifies the type of the serialized polymorphic object. Combined with an explicit serial name defined with the `@SerialName` annotation, this approach gives you full control over the resulting JSON structure:

```kotlin
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to use a custom class discriminator
val format = Json { classDiscriminator = "#class" }

@Serializable
sealed class Project {
    abstract val name: String
}

// Specifies a custom serial name for the OwnedProject class
@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project()

// Specifies a custom serial name for the SimpleProject class
@Serializable
@SerialName("simple")
class SimpleProject(override val name: String) : Project()

fun main() {
    val simpleProject: Project = SimpleProject("kotlinx.serialization")
    val ownedProject: Project = OwnedProject("kotlinx.coroutines", "kotlin")

    // Serializes SimpleProject with #class: "simple"
    println(format.encodeToString(simpleProject))
    // {"#class":"simple","name":"kotlinx.serialization"}

    // Serializes OwnedProject with #class: "owned"
    println(format.encodeToString(ownedProject))
    // {"#class":"owned","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

While the `classDiscriminator` property in a `Json` instance lets you specify a single discriminator key for all polymorphic types, the Experimental `@JsonClassDiscriminator` annotation offers more flexibility. It allows you to define a custom discriminator directly on the base class, which is automatically inherited by all its subclasses.

> To learn more about inheritable serial annotations, see `@InheritableSerialInfo`.

Here's an example:

```kotlin
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// The @JsonClassDiscriminator annotation is inheritable, so all subclasses of Base will have the same
discriminator
@Serializable
@OptIn(ExperimentalSerializationApi::class)
@JsonClassDiscriminator("message_type")
sealed class Base

// Inherits the discriminator from Base
@Serializable
sealed class ErrorClass: Base()

// Defines a class that combines a message and an optional error
@Serializable
data class Message(val message: Base, val error: ErrorClass?)

@Serializable
@SerialName("my.app.BaseMessage")
data class BaseMessage(val message: String) : Base()

@Serializable
@SerialName("my.app.GenericError")
data class GenericError(@SerialName("error_code") val errorCode: Int) : ErrorClass()

val format = Json { classDiscriminator = "#class" }

fun main() {
    val data = Message(BaseMessage("not found"), GenericError(404))
    // Uses the discriminator from Base for all subclasses
    println(format.encodeToString(data))
    // {"message":{"message_type":"my.app.BaseMessage","message":"not found"},"error":
{"message_type":"my.app.GenericError","error_code":404}}
}
```

You can't specify different class discriminators in subclasses of a sealed base class. Only hierarchies with distinct, non-overlapping subclasses can define their own discriminators.

When both specify a discriminator, `@JsonClassDiscriminator` takes priority over the one in the `Json` configuration.

Set class discriminator output mode

Use the `JsonBuilder.classDiscriminatorMode` property to control how class discriminators are added to your JSON output. By default, the discriminator is only added for polymorphic types, which is useful when working with polymorphic class hierarchies.

To adjust this behavior, set the `ClassDiscriminatorMode` property to one of these options:

- `POLYMORPHIC` : (default) adds the class discriminator only for polymorphic types.
- `ALL_JSON_OBJECTS` : adds the class discriminator to all JSON objects, wherever possible.
- `NONE` : omits the class discriminator entirely.

Here's an example with the `ClassDiscriminatorMode` property set to `NONE` :

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to omit the class discriminator from the output
val format = Json { classDiscriminatorMode = ClassDiscriminatorMode.NONE }

@Serializable
sealed class Project {
    abstract val name: String
}

@Serializable
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")
    // Serializes without a discriminator
    println(format.encodeToString(data))
    // {"name":"kotlinx.coroutines","owner":"kotlin"}
}
```

Without the discriminator, the Kotlin serialization library can't deserialize the output back into the appropriate type.

Pretty printing

By default, `Json` produces a compact, single-line output.

You can add indentations and line breaks for better readability by enabling pretty printing in the output. To do so, set the `prettyPrint` property to `true` in a `Json` instance:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Creates a custom Json format
val format = Json { prettyPrint = true }

@Serializable
data class Project(val name: String, val language: String)

fun main() {
    val data = Project("kotlinx.serialization", "Kotlin")

    // Prints the JSON output with line breaks and indentations
    println(format.encodeToString(data))
}
```

This example prints the following result:

```
{
    "name": "kotlinx.serialization",
    "language": "Kotlin"
}
```

You can use the `prettyPrintIndent` option to customize the indentation used in pretty-printed JSON.

For example, you can replace the default four spaces with any allowed whitespace characters, such as `\t` or `\n`.

Customize JSON deserialization

Kotlin's `Json` parser offers several settings that allow you to customize the parsing and deserialization of JSON data.

Ignore unknown keys

When working with JSON data from third-party services or other dynamic sources, new properties may be added to the JSON objects over time.

By default, unknown keys (the property names in the JSON input) result in an error during deserialization. To prevent this, set the `ignoreUnknownKeys` property to `true` in a `Json` instance:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Creates a Json instance to ignore unknown keys
val format = Json { ignoreUnknownKeys = true }

@Serializable
data class Project(val name: String)

fun main() {
    val data = format.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","language":"Kotlin"}
    """)
    // The language key is ignored because it's not in the Project class
    println(data)
    // Project(name=kotlinx.serialization)
}
```

Experimental

Ignore unknown keys for specific classes

Instead of enabling `ignoreUnknownKeys` for all classes, you can ignore unknown keys only for specific classes by using the `@JsonIgnoreUnknownKeys` annotation. This allows you to keep strict deserialization by default while allowing leniency only where needed.

The `@JsonIgnoreUnknownKeys` annotation is Experimental. To opt in, use the `@OptIn(ExperimentalSerializationApi::class)` annotation or the compiler option `-opt-in=kotlinx.serialization.ExperimentalSerializationApi`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@OptIn(ExperimentalSerializationApi::class)
@Serializable
// Unknown properties in Outer are ignored during deserialization
@JsonIgnoreUnknownKeys
data class Outer(val a: Int, val inner: Inner)

@Serializable
data class Inner(val x: String)

fun main() {
    val outer = Json.decodeFromString<Outer>(
        """{"a":1,"inner":{"x":"value"},"unknownKey":42}"""
    )
    println(outer)
    // Outer(a=1, inner=Inner(x=value))

    // Throws an exception
    // unknownKey inside inner is NOT ignored because Inner is not annotated
    println(
        Json.decodeFromString<Outer>(
            """{"a":1,"inner":{"x":"value","unknownKey":"unexpected"}}"""
        )
    )
}
```

In this example, `Inner` throws a `SerializationException` for unknown keys because it isn't annotated with `@JsonIgnoreUnknownKeys`.

Coerce input values

When working with JSON data from third-party services or other dynamic sources, the format can evolve. This may cause exceptions during decoding when actual values don't match the expected types.

The default `Json` implementation is strict about input types. To relax this restriction, set the `coerceInputValues` property to `true` in a `Json` instance:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

val format = Json { coerceInputValues = true }

@Serializable
data class Project(val name: String, val language: String = "Kotlin")

fun main() {
    val data = format.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","language":null}
    """)

    // Coerces the invalid null value for language to its default value
    println(data)
    // Project(name=kotlinx.serialization, language=Kotlin)
}
```

The `coerceInputValues` property only affects decoding. It treats certain invalid input values as if the corresponding property were missing. Currently, it applies to:

- `null` inputs for non-nullable types
- unknown values for enums

> This list may be expanded in future versions, making `Json` instances with this property even more permissive by replacing invalid values with defaults or `null`.

If a value is missing, it's replaced with a default property value if one exists.

For enums, the value is replaced with `null` only if:

- No default is defined.
- The `explicitNulls` property is set to `false`.
- The property is nullable.

You can combine `coerceInputValues` with the `explicitNulls` property to handle invalid enum values:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

enum class Color { BLACK, WHITE }

@Serializable
data class Brush(val foreground: Color = Color.BLACK, val background: Color?)

val json = Json {
  coerceInputValues = true
  explicitNulls = false
}

fun main() {

    // Coerces the unknown foreground value to its default and background to null
    val brush = json.decodeFromString<Brush>("""{"foreground":"pink", "background":"purple"}""")
    println(brush)
    // Brush(foreground=BLACK, background=null)
}
```

Allow trailing commas

To allow trailing commas in JSON input, set the `allowTrailingComma` property to `true`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Allows trailing commas in JSON objects and arrays
val format = Json { allowTrailingComma = true }

fun main() {
    val numbers = format.decodeFromString<List<Int>>(
        """
            [1, 2, 3,]
        """
    )
    println(numbers)
    // [1, 2, 3]
}
```

Allow comments in JSON

Use the `allowComments` property to allow comments in JSON input. When this property is enabled, the parser accepts the following comment forms in the input:

- `//` line comments that end at a newline `\n`
- `/* */` block comments

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Allows comments in JSON input
val format = Json { allowComments = true }

fun main() {
    val numbers = format.decodeFromString<List<Int>>(
        """
            [
                // first element
                1,
                /* second element */
                2
            ]
        """
    )
    println(numbers)
    // [1, 2]
}
```

Lenient parsing

By default, the `Json` parser enforces strict JSON rules to ensure compliance with the RFC-8259 specification, which requires keys and string literals to be quoted.

To relax these restrictions, set the `isLenient` property to `true` in a `Json` instance:

```kotlin
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

val format = Json { isLenient = true }

enum class Status { SUPPORTED }

@Serializable
data class Project(val name: String, val status: Status, val votes: Int)

fun main() {
    // Decodes a JSON string with lenient parsing
    // Lenient parsing allows unquoted keys, string, and enum values
    val data = format.decodeFromString<Project>("""
        {
            name   : kotlinx.serialization,
            status : SUPPORTED,
            votes  : "9000"
        }
    """)
    println(data)
    // Project(name=kotlinx.serialization, status=SUPPORTED, votes=9000)
}
```

Customize name mapping between JSON and Kotlin

Some JSON data may not perfectly align with Kotlin's naming conventions or expected formats. To address these challenges, the Kotlin serialization library provides several tools to manage naming discrepancies, handle multiple JSON property names, and ensure consistent naming strategies across serialized data.

Accept alternative JSON property names for a single Kotlin property

When JSON property names change between schema versions, you can use the `@SerialName` annotation to rename a JSON property.

However, this prevents decoding data that still uses previous property names. To accept alternative JSON property names for a single property, use the `@JsonNames` annotation:

```kotlin
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
// Maps both name and title JSON properties to the name property
data class Project(@JsonNames("title") val name: String)

fun main() {
    val project = Json.decodeFromString<Project>("""{"name":"kotlinx.serialization"}""")
    println(project)
    // Project(name=kotlinx.serialization)

    val oldProject = Json.decodeFromString<Project>("""{"title":"kotlinx.coroutines"}""")
    // Both name and title Json properties correspond to name property
    println(oldProject)
    // Project(name=kotlinx.coroutines)
}
```

The `useAlternativeNames` property in `JsonBuilder` enables the `@JsonNames` annotation. This property is set to `true` by default and allows `Json` to recognize and decode multiple names for a single property.

If you aren't using `@JsonNames` and want to improve performance, especially when skipping many unknown properties with `ignoreUnknownKeys`, you can set this property to `false`.

Decode enums in a case-insensitive manner

Kotlin's naming conventions recommend naming enum values in uppercase with underscores or in upper camel case. By default, `Json` uses the exact names of Kotlin enum constants when decoding.

However, JSON data from external sources might use lowercase or mixed-case names. To handle such cases, configure the `Json` instance to decode enum values case-insensitively with the `JsonBuilder.decodeEnumsCaseInsensitive` property:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Configures a Json instance to decode enum values in a case-insensitive way
val format = Json { decodeEnumsCaseInsensitive = true }

enum class Cases { VALUE_A, @JsonNames("Alternative") VALUE_B }

@Serializable
data class CasesList(val cases: List<Cases>)

fun main() {
    // Decodes enum values regardless of their case, including alternative names
    println(format.decodeFromString<CasesList>("""{"cases":["value_A", "alternative"]}"""))
    // CasesList(cases=[VALUE_A, VALUE_B])
}
```

This property applies to both serial names and alternative names specified with the `@JsonNames` annotation, ensuring that all values are decoded successfully. This property doesn't affect encoding.

Apply a global naming strategy

When property names in JSON input differ from those in Kotlin, you can specify the name of each property explicitly using the `@SerialName` annotation. However, when migrating from other frameworks or a legacy codebase, you might need to transform every serial name in the same way.

For these scenarios, you can specify a global naming strategy using the JsonBuilder.namingStrategy property in a `Json` instance. The Kotlin serialization library provides built-in strategies, such as JsonNamingStrategy.SnakeCase:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class Project(val projectName: String, val projectOwner: String)

// Configures a Json instance to apply SnakeCase naming strategy
val format = Json { namingStrategy = JsonNamingStrategy.SnakeCase }

fun main() {
    val project = format.decodeFromString<Project>("""{"project_name":"kotlinx.coroutines",
"project_owner":"Kotlin"}""")
    // Serializes and deserializes as if all serial names are transformed from camel case to snake
case
    println(format.encodeToString(project.copy(projectName = "kotlinx.serialization")))
    // {"project_name":"kotlinx.serialization","project_owner":"Kotlin"}
}
```

When using a global naming strategy with `JsonNamingStrategy`, keep the following in mind:

- *The transformation applies to all properties*, whether the serial name is derived from the property name or explicitly defined with the `@SerialName` annotation. You can't exclude a property from transformation by specifying a serial name. To keep specific names unchanged during serialization, use the `@JsonNames` annotation instead.
- If a transformed name conflicts with other transformed property names or with alternative names specified by the `@JsonNames` annotation, deserialization fails with an exception.
- Global naming strategies are implicit. It makes it difficult to determine the serialized names by looking at the class definition. This can make tasks like **Find Usages**, and **Rename** in IDEs, or full-text searches using tools like `grep`, more difficult, potentially increasing the risk of bugs and maintenance costs.

Given these factors, consider the trade-offs carefully before implementing global naming strategies in your application.

What's next

- Explore advanced JSON element handling to manipulate and work with JSON data before it's parsed or serialized.
- Discover how to transform JSON during serialization and deserialization for more control over your data.

JSON elements

The Kotlin serialization library also supports working with JSON at a structural level. You can use the `JsonElement` API, to inspect, modify, and build JSON structures directly before converting them into a Kotlin type or a string.

`JsonElement` has three direct subtypes that represent the core JSON structures:

- `JsonPrimitive` handles primitive JSON elements such as strings, numbers, booleans, and `null`. The `null` value is represented by a special subclass of `JsonPrimitive`, called `JsonNull`. Each `JsonPrimitive` stores a string representation of its value, which you can access through its `JsonPrimitive.content` property.
- `JsonArray` represents a JSON array. It's a Kotlin `List` of `JsonElement` items.
- `JsonObject` represents a JSON object. It's a Kotlin `Map` with `String` keys and `JsonElement` values.

Parse strings to JSON elements

You can parse a string into a `JsonElement` to work with the JSON structure before converting it into a Kotlin type or a string.

Use the `Json.parseToJsonElement()` function to parse the input into a JSON element tree without decoding or deserializing it:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

fun main() {
    val element = Json.parseToJsonElement("""
        {"name":"kotlinx.serialization","language":"Kotlin"}
    """)
    // JsonElement.toString() gives you a valid JSON string
    println(element)
    // {"name":"kotlinx.serialization","language":"Kotlin"}
}
```

Access the contents of JSON elements

You can access the contents of a JSON element directly through the extension properties of the `JsonElement` API. These extension properties cast the element to a specific subtype and throw an `IllegalArgumentException` if the element doesn't have the expected JSON structure.

The available extension properties are:

- `jsonPrimitive` returns a `JsonPrimitive`.
- `jsonArray` returns a `JsonArray`.
- `jsonObject` returns a `JsonObject`.

Similarly, `JsonPrimitive` has extension properties for parsing the value as Kotlin primitive types, such as `int`, `intOrNull`, `long`, and `longOrNull`.

Here's an example of how you can use these extension properties when processing JSON data with a known structure:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

fun main() {
    val element = Json.parseToJsonElement("""
        {
            "name": "kotlinx.serialization",
            "forks": [{"votes": 42}, {"votes": 9000}, {}]
        }
    """)
    val sum = element
        // Accesses the forks key from the JsonObject
        .jsonObject["forks"]!!

        // Accesses the value as a JsonArray and sums the votes values from each JsonObject as Int
        .jsonArray.sumOf { it.jsonObject["votes"]?.jsonPrimitive?.int ?: 0 }
    println(sum)
    // 9042
}
```

If you don't know the JSON structure in advance, you can check the element type and handle each `JsonElement` subtype explicitly. For example, you can use a helper function with a `when` expression:

```
fun processElement(element: JsonElement): String = when (element) {
    is JsonObject -> "JsonObject with keys: ${element.keys}"
    is JsonArray -> "JsonArray with ${element.size} elements"
    is JsonPrimitive -> "JsonPrimitive with content: ${element.content}"
}
```

Create JSON elements

You can create instances of specific `JsonElement` subtypes directly.

To create a `JsonPrimitive`, use the `JsonPrimitive()` function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

fun main() {
    // Creates JsonPrimitive values from different Kotlin primitives
    val number = JsonPrimitive(42)
    val text = JsonPrimitive("kotlinx.serialization")

    println(number)
    // 42
    println(text)
    // "kotlinx.serialization"
}
```

You can create `JsonArray` and `JsonObject` elements either by directly calling their constructors or by using the builder functions:

- To create a `JsonArray` from a `List`, use `JsonArray()`, or use the `buildJsonArray()` builder function.
- To create a `JsonObject` from a `Map`, use `JsonObject()`, or use the `buildJsonObject()` builder function.

The builder functions provide a DSL similar to Kotlin's standard library collection builders with JSON-specific overloads and inner builder functions.

Here's an example that highlights the key features of the JSON builder DSLs:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

fun main() {
    val element = buildJsonObject {
        // Adds a simple key-value pair to the JsonObject
        put("name", "kotlinx.serialization")
        // Adds a nested JsonObject under the owner key
        putJsonObject("owner") {
            put("name", "kotlin")
        }
        // Adds a JsonArray with multiple JsonObjects
        putJsonArray("forks") {
            // Adds a JsonObject to the JsonArray
            addJsonObject {
                put("votes", 42)
            }
            addJsonObject {
                put("votes", 9000)
            }
        }
    }
    // Prints the resulting JSON string
    println(element)
    // {"name":"kotlinx.serialization","owner":{"name":"kotlin"},"forks":[{"votes":42},
{"votes":9000}]}
}
```

Encode literal JSON content

While the JSON specification doesn't restrict the size or precision of numbers, serializing numbers of arbitrary size with the `JsonPrimitive()` function might lead to some issues.

For example, if you use `Double` for large numbers, the value might get truncated and you lose precision. If you use Kotlin/JVM `BigDecimal`, the value stays precise, but `JsonPrimitive()` encodes the value as a string rather than as a number:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import java.math.BigDecimal

val format = Json { prettyPrint = true }

fun main() {
    val pi = BigDecimal("3.14159265358979323846264338327 9")

    // Converts the BigDecimal to a Double, causing potential truncation
    val piJsonDouble = JsonPrimitive(pi.toDouble())
    // Converts the BigDecimal to a String, preserving the precision but treating it as a string in
JSON
    val piJsonString = JsonPrimitive(pi.toString())

    val piObject = buildJsonObject {
        put("pi_double", piJsonDouble)
        put("pi_string", piJsonString)
    }

    println(format.encodeToString(piObject))
    // "pi_double": 3.141592653589793,
    // "pi_string": "3.14159265358979323846264338327 9"
}
```

In this example, even though `pi` is defined as a number with 30 decimal places, the resulting JSON doesn't preserve that precision. The `Double` value is truncated to 15 decimal places, and the `String` value is wrapped in quotes, so it becomes a JSON string rather than a number.

To avoid these issues, you can encode an arbitrary unquoted value, such as the string value of `pi` in this example, using the `JsonUnquotedLiteral()` function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import java.math.BigDecimal

val format = Json { prettyPrint = true }

fun main() {
    val pi = BigDecimal("3.14159265358979323846264338327 9")

    // Encodes the raw JSON content using JsonUnquotedLiteral()
    @OptIn(ExperimentalSerializationApi::class)
    val piJsonLiteral = JsonUnquotedLiteral(pi.toString())

    // Converts to Double and String
    val piJsonDouble = JsonPrimitive(pi.toDouble())
    val piJsonString = JsonPrimitive(pi.toString())

    val piObject = buildJsonObject {
        put("pi_literal", piJsonLiteral)
        put("pi_double", piJsonDouble)
        put("pi_string", piJsonString)
    }

    // pi_literal now accurately matches the value defined
    println(format.encodeToString(piObject))
    // "pi_literal": 3.14159265358979323846264338327 9,
    // "pi_double": 3.141592653589793,
    // "pi_string": "3.14159265358979323846264338327 9"
}
```

To decode `pi` back to a `BigDecimal`, extract the string content of the `JsonPrimitive`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import java.math.BigDecimal

fun main() {
    val piObjectJson = """
          {
              "pi_literal": 3.14159265358979323846264338327 9
          }
      """.trimIndent()

    // Decodes the JSON string into a JsonObject
    val piObject: JsonObject = Json.decodeFromString(piObjectJson)

    // Extracts the string content from the JsonPrimitive
    val piJsonLiteral = piObject["pi_literal"]!!.jsonPrimitive.content

    // Converts the string to a BigDecimal
    val pi = BigDecimal(piJsonLiteral)
    // Prints the decoded value of pi, preserving all 30 decimal places
    println(pi)
    // 3.14159265358979323846264338327 9
}
```

This example uses a `JsonPrimitive` for simplicity. For more reusable approaches, see Json Transformations.

JSON null literal

To avoid creating an inconsistent state, you can't encode the string `"null"` with the `JsonUnquotedLiteral()` function. If you try to do so, an exception is thrown:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@OptIn(ExperimentalSerializationApi::class)
fun main() {
    JsonUnquotedLiteral("null")
    // Exception in thread "main" kotlinx.serialization.json.internal.JsonEncodingException
}
```

To represent a JSON `null` literal value, use `JsonNull`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

fun main() {
    val possiblyNull = JsonNull

    println(possiblyNull)
    // null
}
```

Decode Json elements

To decode an instance of the `JsonElement` class into a serializable object, use the `Json.decodeFromJsonElement()` function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
data class Project(val name: String, val language: String)

fun main() {
    val element = buildJsonObject {
        put("name", "kotlinx.serialization")
        put("language", "Kotlin")
    }

    // Decodes the JsonElement into a Project object
    val data = Json.decodeFromJsonElement<Project>(element)
    println(data)
    // Project(name=kotlinx.serialization, language=Kotlin)
}
```

What's next

- Discover how to transform JSON during serialization and deserialization for more control over your data.
- Learn how to serialize classes and how to modify the default behavior of the `@Serializable` annotation.

Transform JSON structure

To control the structure and content of the JSON generated during serialization, you can create custom serializers. For smaller adjustments, such as wrapping values or unwrapping arrays, the `JsonTransformingSerializer` class provides a simpler way to modify JSON by working directly with the JSON element tree instead of using the `Encoder` or `Decoder` manually.

> These sections are based on concepts explained in Create and use serializers. If you're not familiar with custom serializers, we recommend reading that page first.

The `JsonTransformingSerializer` is a JSON-specific abstract serializer that implements the `KSerializer` interface. It provides the `transformSerialize()` and `transformDeserialize()` functions that you can override to adjust the JSON element tree before serialization or deserialization.

In addition to transforming JSON structures, you can also use `JsonContentPolymorphicSerializer` to select the appropriate polymorphic class based on the JSON content.

Modify JSON structure

You can adjust the JSON structure by transforming the JSON element tree. The following examples demonstrate common use cases, such as wrapping or unwrapping arrays and omitting specific properties.

Wrap a single object in an array during deserialization

Some APIs return a single JSON object for one item and a JSON array for multiple items. To deserialize both cases into a `List`:

1. Create a subclass of `JsonTransformingSerializer` and specify a serializer in its constructor. To use the standard conversion logic, pass the default serializer for the target type, such as `ListSerializer()` for lists.
2. Override the `transformDeserialize()` function.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*

@Serializable
data class Project(
    val name: String,
    // Specifies UserListSerializer to handle the serialization of the users property
    @Serializable(with = UserListSerializer::class)
    val users: List<User>
)

@Serializable
data class User(val name: String)

// Creates a serializer that transforms the results of the default List serializer
object UserListSerializer : JsonTransformingSerializer<List<User>>(ListSerializer(User.serializer()))
{
    override fun transformDeserialize(element: JsonElement): JsonElement =
        // If the element is not a JsonArray, wraps it into a single-element array
        if (element !is JsonArray) JsonArray(listOf(element)) else element
}

fun main() {
    println(Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","users":{"name":"kotlin"}}
    """))
    // Project(name=kotlinx.serialization, users=[User(name=kotlin)])

    println(Json.decodeFromString<Project>("""
        {"name":"kotlinx.serialization","users":[{"name":"kotlin"},{"name":"jetbrains"}]}
    """))
    // Project(name=kotlinx.serialization, users=[User(name=kotlin), User(name=jetbrains)])
}
```

Unwrap a single-element array during serialization

To unwrap a single-element list into a single JSON object during serialization, override the `transformSerialize()` function:

```kotlin
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*

@Serializable
data class Project(
    val name: String,
    // Specifies UserListSerializer to handle serialization of the users property
    @Serializable(with = UserListSerializer::class)
    val users: List<User>
)

@Serializable
data class User(val name: String)

// Creates a serializer that transforms the results of the default List serializer
object UserListSerializer : JsonTransformingSerializer<List<User>>(ListSerializer(User.serializer()))
{

    override fun transformSerialize(element: JsonElement): JsonElement {
        require(element is JsonArray)
        // Unwraps single-element lists into a single JSON object
        return element.singleOrNull() ?: element
    }
}

fun main() {
    val data = Project("kotlinx.serialization", listOf(User("kotlin")))
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","users":{"name":"kotlin"}}
}
```

Omit specific properties during serialization

If you can't specify a default value, but still want to omit a property when it has a specific value, use `JsonTransformingSerializer`:

1. Create a subclass of `JsonTransformingSerializer` and specify a serializer in its constructor.
2. Override the `transformSerialize()` function.

Here's an example where the `Project` class has a `language` property, which is omitted when its value is `"Kotlin"`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*

@Serializable
class Project(val name: String, val language: String)

// Creates a custom serializer that omits the language property if it's equal to "Kotlin"
object ProjectSerializer : JsonTransformingSerializer<Project>(Project.serializer()) {
    override fun transformSerialize(element: JsonElement): JsonElement =
        // Omits the language property if its value is "Kotlin"
        JsonObject(element.jsonObject.filterNot {
            (k, v) -> k == "language" && v.jsonPrimitive.content == "Kotlin"
        })
}

fun main() {
    val data = Project("kotlinx.serialization", "Kotlin")

    // Uses the default serializer
    println(Json.encodeToString(data))
    // {"name":"kotlinx.serialization","language":"Kotlin"}

    // Applies the custom serializer to omit the language property
    println(Json.encodeToString(ProjectSerializer, data))
    // {"name":"kotlinx.serialization"}
}
```

When serializing an object directly, you need to explicitly pass the custom serializer to the `encodeToString()` function to ensure that the custom serialization logic is applied. For more information, see Pass serializers manually.

Select the appropriate polymorphic class based on the JSON content

In polymorphic serialization, JSON often contains a dedicated *class discriminator* property that identifies the concrete subtype during deserialization.

If the JSON input doesn't contain a class discriminator, you can use `JsonContentPolymorphicSerializer` to infer the type from the structure of the JSON. This serializer lets you override the `selectDeserializer()` function to choose the correct deserializer based on the JSON content.

Here's an example where all values share a common base type with a `name` property:

```
@Serializable
abstract class Project {
    abstract val name: String
}

@Serializable
data class BasicProject(override val name: String): Project()

@Serializable
data class OwnedProject(override val name: String, val owner: String) : Project()
```

In this example, the serializer chooses which subtype to use based on the JSON content, so you don't need a `sealed` class for the class hierarchy.

To distinguish between `BasicProject` and `OwnedProject`, override the `selectDeserializer()` function. You can use this function to check whether the JSON object contains the `owner` key, and return the corresponding serializer:

```
// Creates a custom serializer that selects deserializer based on the presence of "owner"
object ProjectSerializer : JsonContentPolymorphicSerializer<Project>(Project::class) {
    override fun selectDeserializer(element: JsonElement) = when {
        // Selects the OwnedProject serializer if the JSON object contains an "owner" key
        "owner" in element.jsonObject -> OwnedProject.serializer()
        else -> BasicProject.serializer()
    }
}
```

When you use this serializer to serialize data, Kotlin serialization uses the serializer of the value's actual runtime type. This could be the serializer specified in a `SerializersModule` or the default serializer:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*

@Serializable
abstract class Project {
    abstract val name: String
}

@Serializable
data class BasicProject(override val name: String): Project()

@Serializable
data class OwnedProject(override val name: String, val owner: String) : Project()

// Creates a custom serializer that selects deserializer based on the presence of "owner"
object ProjectSerializer : JsonContentPolymorphicSerializer<Project>(Project::class) {
    override fun selectDeserializer(element: JsonElement) = when {
        // Selects the OwnedProject serializer if the JSON object contains an "owner" key
        "owner" in element.jsonObject -> OwnedProject.serializer()
        else -> BasicProject.serializer()
    }
}

fun main() {
    val data = listOf(
        OwnedProject("kotlinx.serialization", "kotlin"),
        BasicProject("example")
    )
    // No class discriminator in the JSON output
    val string = Json.encodeToString(ListSerializer(ProjectSerializer), data)

    println(string)
    // [{"name":"kotlinx.serialization","owner":"kotlin"},{"name":"example"}]

    println(Json.decodeFromString(ListSerializer(ProjectSerializer), string))
    // [OwnedProject(name=kotlinx.serialization, owner=kotlin), BasicProject(name=example)]
}
```

Experimental

Add custom behavior to the default serializer

You can add custom behavior to the default serializer that Kotlin serialization generates, by using the default serializer as a delegate.

To do so, annotate a serializable class with the Experimental `@KeepGeneratedSerializer` and use the automatically generated `generatedSerializer()` as the base serializer in your custom `JsonTransformingSerializer`.

Here's an example that updates the JSON structure during deserialization by combining multiple input properties into a single `name` property expected by the target class:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@OptIn(ExperimentalSerializationApi::class)
@KeepGeneratedSerializer
@Serializable(with = UserNameSerializer::class)
// Defines a type with a name property
data class User(val name: String)

// Adds custom logic to the default serializer to combine input properties during deserialization
object UserNameSerializer : JsonTransformingSerializer<User>(User.generatedSerializer()) {
    override fun transformDeserialize(element: JsonElement): JsonElement {
        val jsonObject = element.jsonObject
        val first = jsonObject["firstName"]?.jsonPrimitive?.content
        val last = jsonObject["lastName"]?.jsonPrimitive?.content

        // Combines input properties into the name property
        // if the input doesn't match the expected structure
        return if (first ≠ null && last ≠ null) {
            JsonObject(mapOf("name" to JsonPrimitive("$first $last")))
        } else {
            jsonObject
        }
    }
}

fun main() {
    // Deserializes JSON where the name property is split across multiple input properties
   val fromExternalData = Json.decodeFromString<User>(
        """{"firstName":"John","lastName":"Smith"}"""
    )
    println(fromExternalData)
    // User(name=John Smith)

    // Deserializes JSON where the name property matches the expected structure
    val fromInternalData = Json.decodeFromString<User>(
        """{"name":"John Smith"}"""
    )
    println(fromInternalData)
    // User(name=John Smith)
}
```

Experimental

Implement custom serialization logic in JSON

If the transformation functions provided by `JsonTransformingSerializer` or `JsonContentPolymorphicSerializer` aren't enough, you can implement custom serialization logic by defining your own `KSerializer` class.

You can get full control over how values are serialized and deserialized by overriding the `serialize()` and `deserialize()` functions directly.

When you implement custom serialization logic for JSON, you can cast `Encoder` to `JsonEncoder` and `Decoder` to `JsonDecoder` to call the JSON-specific functions `decodeJsonElement()` and `encodeToJsonElement()`. These functions allow you to retrieve JSON elements from the value the decoder is currently handling, or insert JSON elements into it.

Both `JsonDecoder` and `JsonEncoder` expose a `json` property that gives access to the active `Json` instance, which controls how values are encoded and decoded. Through that instance, you can use `encodeToJsonElement()` and `decodeFromJsonElement()` to convert between `JsonElement` instances and Kotlin objects.

Using these APIs, you can implement two-stage conversions:

- Decode the input into a `JsonElement` first and then convert that element into a Kotlin value.
- Convert a Kotlin value into a `JsonElement` first and then encode that element with the encoder.

Let's look at an example of a custom `KSerializer` that fully controls how values of a `Response` type are encoded and decoded in JSON. This serializer encodes an `Ok` response directly as a JSON value and an `Error` response as a JSON object that contains the error message:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.encoding.*

// Defines a sealed class for API responses
@Serializable(with = ResponseSerializer::class)
sealed class Response<out T> {
    data class Ok<out T>(val data: T) : Response<T>()
    data class Error(val message: String) : Response<Nothing>()
}

// Implements custom serialization logic for Response
class ResponseSerializer<T>(
    private val dataSerializer: KSerializer<T>
) : KSerializer<Response<T>> {
    override val descriptor: SerialDescriptor = buildClassSerialDescriptor("Response") {
        element("Ok", dataSerializer.descriptor)
        element("Error", buildClassSerialDescriptor("Error") {
            element<String>("message")
        })
    }
    // Deserializes a Response value from JSON
    override fun deserialize(decoder: Decoder): Response<T> {
        // Ensures that the decoder is a JsonDecoder
        require(decoder is JsonDecoder)

        // Decodes the input into a JsonElement
        val element = decoder.decodeJsonElement()

        // Converts the JsonElement into the corresponding Response value
        return if (element is JsonObject && "error" in element) {
            Response.Error(element["error"]!!.jsonPrimitive.content)
        } else {
            Response.Ok(
                decoder.json.decodeFromJsonElement(dataSerializer, element)
            )
        }
    }

    // Serializes a Response value to JSON
    override fun serialize(encoder: Encoder, value: Response<T>) {
        // Ensures that the encoder is a JsonEncoder
        require(encoder is JsonEncoder)

        // Converts the Response value into a JsonElement
        val element = when (value) {
            is Response.Ok ->
                encoder.json.encodeToJsonElement(dataSerializer, value.data)
            is Response.Error ->
                buildJsonObject { put("error", value.message) }
        }

        // Encodes the JsonElement using the encoder
        encoder.encodeJsonElement(element)
    }
}

@Serializable
data class Project(val name: String)
```

```
fun main() {
    val responses = listOf(
        Response.Ok(Project("kotlinx.serialization")),
        Response.Error("Not found")
    )

    val json = Json.encodeToString(responses)
    println(json)
    // [{"name":"kotlinx.serialization"},{"error":"Not found"}]

    println(Json.decodeFromString<List<Response<Project>>>(json))
    // [Ok(data=Project(name=kotlinx.serialization)), Error(message=Not found)]
}
```

Preserve unknown JSON attributes

A common use case for a custom JSON-specific serializer is preserving JSON properties from the input that your serializable class doesn't define. By default, these properties are ignored during deserialization.

To preserve these JSON properties, implement a custom JSON-specific serializer that collects all properties not defined in the target class into a dedicated `JsonObject` field during deserialization. This allows you to preserve these properties in the serializable class without modifying the original JSON structure.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*
import kotlinx.serialization.json.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.encoding.*

data class UnknownProject(val name: String, val details: JsonObject)

object UnknownProjectSerializer : KSerializer<UnknownProject> {
    override val descriptor: SerialDescriptor = buildClassSerialDescriptor("UnknownProject") {
        element<String>("name")
        element<JsonElement>("details")
    }

    override fun deserialize(decoder: Decoder): UnknownProject {
        // Ensures the decoder is JSON-specific
        val jsonInput = decoder as? JsonDecoder ?: error("Can be deserialized only by JSON")

        // Reads the entire content as JSON
        val json = jsonInput.decodeJsonElement().jsonObject

        // Extracts and removes the name property
        val name = json.getValue("name").jsonPrimitive.content
        val details = json.toMutableMap()
        details.remove("name")
        return UnknownProject(name, JsonObject(details))
    }

    override fun serialize(encoder: Encoder, value: UnknownProject) {
        error("Serialization is not supported")
    }
}

fun main() {
    // Deserializes JSON with properties not defined in the serializable class into UnknownProject
    println(Json.decodeFromString(UnknownProjectSerializer, """
{"type":"unknown","name":"example","maintainer":"Unknown","license":"Apache 2.0"}"""))
    // UnknownProject(name=example, details={"type":"unknown","maintainer":"Unknown","license":"Apache
2.0"})

}
```

In this example, the preserved JSON properties remain at the same level within the input JSON object as the properties defined in the serializable class.

What's next

- Learn how to serialize polymorphic classes and handle objects of various types within a shared hierarchy.
- Discover other serialization formats, such as CBOR and ProtoBuf.

Experimental

Serialize JSON with I/O sources

The Kotlin serialization library provides APIs for working with JVM streams and `kotlinx-io` or Okio sources and sinks.

You can use these APIs to serialize and deserialize JSON directly from I/O sources without creating intermediate strings. These APIs use UTF-8 encoding and throw `SerializationException` for invalid JSON data and `IOException` for I/O failures.

When working with I/O resources, it's important to close them properly to prevent resource leaks. You can do this with the `.use()` function, which closes the resource automatically when the operation completes.

Serialize JSON to JVM output streams

Use the `.encodeToStream()` extension function to serialize JSON directly to a JVM `OutputStream`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import java.io.FileOutputStream

@Serializable
data class Project(val name: String, val stars: Int)

fun main() {
    val project = Project("kotlinx.serialization", 9000)

    // Creates an OutputStream for the project.json file
    FileOutputStream("project.json").use { output ->

        // Serializes the project instance into the OutputStream
        Json.encodeToStream(project, output)
    }
}
```

In this example, the JSON representation of `Project` is serialized into the `project.json` file.

Deserialize JSON from JVM input streams

To deserialize JSON directly from a JVM `InputStream`, use the `.decodeFromStream()` extension function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import java.io.FileInputStream

@Serializable
data class Project(val name: String, val stars: Int)

fun main() {
    // Opens an InputStream
    FileInputStream("project.json").use { input ->

        // Deserializes the JSON contents of the InputStream into a Project instance
        val project = Json.decodeFromStream<Project>(input)

        // Prints the deserialized Project instance
        println(project)
    }
}
```

In this example, the JSON contents of the input stream are deserialized into a single `Project` instance.

If your input contains multiple JSON objects in a top-level JSON array or as whitespace-separated objects, you can use `.decodeToSequence()` to process the elements lazily. This lets you handle each value as it is parsed, for example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import java.io.FileInputStream

@Serializable
data class Project(val name: String, val stars: Int)

fun main() {
    // Opens an InputStream for the projects.json file containing a JSON array of Project objects
    FileInputStream("projects.json").use { input ->

        // Lazily deserializes each Project from the InputStream
        val projects = Json.decodeToSequence<Project>(input)

        // Processes elements one by one
        for (project in projects) {
            println(project)
        }
    }
}
```

You can iterate through sequences returned by `.decodeToSequence()` only once because they are tied to the underlying stream.

Accessing a sequence may result in an exception if its underlying stream is closed before the sequence is completely evaluated.

JSON serialization with kotlinx-io and Okio

In addition to JVM streams, you can work with JSON using I/O types, such as `kotlinx.io.Sink` and `kotlinx.io.Source` from the `kotlinx-io` library (currently in Alpha), and `okio.BufferedSink` and `okio.BufferedSource` from the Okio library.

You can use the following `Json` extension functions to read and write JSON directly through these I/O types:

- `.encodeToSink()` and `.encodeToBufferedSink()` to write JSON to a `kotlinx.io.Sink` or `okio.BufferedSink`.
- `.decodeFromSource()` and `.decodeFromBufferedSource()` to read a single JSON value from a `kotlinx.io.Source` or `okio.BufferedSource`.
- `.decodeSourceToSequence()` and `.decodeBufferedSourceToSequence()` to lazily decode multiple JSON values as a `Sequence<T>`.

The next sections cover examples using `kotlinx-io` types with these APIs.
You can use Okio types similarly with their corresponding `okio.BufferedSink` and `okio.BufferedSource` APIs.

Add dependencies for kotlinx-io and Okio

To use the extension functions with `kotlinx-io` or Okio types, add the corresponding dependencies:

Add dependencies for `kotlinx-io`

Gradle

```
// build.gradle(.kts)
dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-serialization-json-io:1.11.0")
    implementation("org.jetbrains.kotlinx:kotlinx-io-core:0.9.1")
}
```

Maven

```
<!-- pom.xml -->
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-serialization-json-io</artifactId>
        <version>1.11.0</version>
    </dependency>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-io-core</artifactId>
        <version>0.9.1</version>
    </dependency>
</dependencies>
```

Add dependencies for Okio

Gradle

```
// build.gradle(.kts)
dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-serialization-json-okio:1.11.0")
    implementation("com.squareup.okio:okio:3.16.2")
}
```

Maven

```
<!-- pom.xml -->
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-serialization-json-okio</artifactId>
        <version>1.11.0</version>
    </dependency>
    <dependency>
        <groupId>com.squareup.okio</groupId>
        <artifactId>okio</artifactId>
        <version>3.16.2</version>
    </dependency>
</dependencies>
```

Serialize JSON to Sinks

To serialize JSON to a `Sink`, use the `.encodeToSink()` function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Imports declarations for kotlinx-io types and JSON I/O support
import kotlinx.serialization.json.io.*
import kotlinx.io.*
import kotlinx.io.files.*

@Serializable
data class Project(val name: String, val stars: Int)

@OptIn(ExperimentalSerializationApi::class)
fun main() {
    val project = Project("kotlinx.serialization", 9000)

    // Creates a Sink for the project.json file
    val path = Path("project.json")
    SystemFileSystem.sink(path).buffered().use { sink: Sink →

        // Serializes the Project instance directly into a Sink
        Json.encodeToSink(project, sink)
    }
}
```

Deserialize JSON from Sources

To deserialize JSON from a `Source`, use the `.decodeFromSource()` function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Imports declarations for kotlinx-io types and JSON I/O support
import kotlinx.serialization.json.io.*
import kotlinx.io.*
import kotlinx.io.files.*

@Serializable
data class Project(val name: String, val stars: Int)

@OptIn(ExperimentalSerializationApi::class)
fun main() {
    // Opens a Source for the project.json file
    val path = Path("project.json")
    SystemFileSystem.source(path).buffered().use { source: Source →

        // Deserializes a Project instance directly from a Source
        val project = Json.decodeFromSource<Project>(source)

        println(project)
    }
}
```

If your input contains a large JSON array or multiple top-level JSON objects, you can turn a `Source` into a lazily decoded `Sequence<T>` with the `.decodeSourceToSequence()` function.

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Imports declarations for kotlinx-io types and JSON I/O support
import kotlinx.serialization.json.io.*
import kotlinx.io.*
import kotlinx.io.files.*

@Serializable
data class Project(val name: String, val stars: Int)

@OptIn(ExperimentalSerializationApi::class)
fun main() {
    // Opens a Source for the projects.json file containing multiple JSON objects
    val path = Path("projects.json")
    SystemFileSystem.source(path).buffered().use { source: Source ->

        // Lazily deserializes each Project as it is read from the Source
        val projects: Sequence<Project> = Json.decodeSourceToSequence(source)

        for (project in projects) {
            println(project)
        }
    }
}
```

You can iterate through sequences returned by `.decodeSourceToSequence()` only once because they are tied to the underlying `Source`.

Accessing a sequence may result in an exception if its underlying source is closed before the sequence is completely evaluated.

What's next

- Learn how to customize Json instances to address different use cases for serialization and deserialization.
- Explore advanced JSON element handling to manipulate and work with JSON data before it's parsed or serialized.
- Discover how to transform JSON during serialization and deserialization for more control over your data.

Serialize polymorphic classes

Polymorphism allows working with objects of different types through a common interface or base class. Kotlin serialization supports subtype polymorphism, allowing different types to be serialized through a common declared supertype.

For an overview of how interfaces and inheritance work in Kotlin, see Interfaces and Inheritance.

Kotlin serialization is *static* by default. It uses the *static type* of the serialized value, which is the declared type of the variable, to determine which properties are encoded.

This means that only the properties defined in that static type are serialized, even if the value is an instance of a subclass at runtime.

Here's an example that uses a polymorphic class hierarchy:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
open class Project(val name: String)

class OwnedProject(name: String, val owner: String) : Project(name)

fun main() {
    // Uses Project as the declared static type
    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")

    // Serializes only properties defined in the static type
    println(Json.encodeToString(data))
    // {"name":"kotlinx.coroutines"}
}
```

In this example, even though the runtime value is the `OwnedProject` subclass, only the properties of the declared `Project` static type are serialized.

To serialize values in a polymorphic class hierarchy, Kotlin serialization provides two approaches:

- Closed polymorphism, where a `sealed` base class or interface ensures that all subclasses are known at compile time.
- Open polymorphism, where you specify subclasses explicitly for an `open` or `abstract` base class.

Serialize closed polymorphic classes

A class hierarchy is considered to use closed polymorphism when all possible subclasses are guaranteed to be known at compile time.

To provide this guarantee, use a `sealed class` or `sealed interface` as the base type. Mark it as `@Serializable`, and mark all subclasses with `@Serializable`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Defines a sealed class as the base type
@Serializable
sealed class Project {
    abstract val name: String
}

// Marks the subclass as serializable
@Serializable
class OwnedProject(override val name: String, val owner: String) : Project()

// Serializes data using the base type as the static type
fun main() {
    // Uses the base type as the static type
    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")

    // A type property is added to identify the serialized subclass
    println(Json.encodeToString(data))
    // {"type":"OwnedProject","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

By default, the `type` property in the JSON output acts as the class discriminator and identifies the serialized subclass. This property is only included if you use the base class as the static type during serialization.

> You can also configure JSON to use a different key name for the class discriminator. For more information, see the Specify class discriminator for polymorphism section.

Here's an example where a subclass is the static type, so the `type` property is omitted:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
sealed class Project {
    abstract val name: String
}

@Serializable
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    // The inferred static type is OwnedProject
    val data = OwnedProject("kotlinx.coroutines", "kotlin")

    // The type property is omitted because the static type is OwnedProject
    println(Json.encodeToString(data))
    // {"name":"kotlinx.coroutines","owner":"kotlin"}
}
```

You can explicitly specify the base type when serializing objects to ensure the `type` property is included in the output. To do so, pass the base type as a type argument to the `encodeToString()` function:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
sealed class Project {
    abstract val name: String
}

@Serializable
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    // The inferred static type is OwnedProject
    val data = OwnedProject("kotlinx.coroutines", "kotlin")

    // Specifies the base type explicitly to make use of polymorphism
    println(Json.encodeToString<Project>(data))
    // {"type":"OwnedProject","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

Define custom serial names for subclasses

By default, Kotlin serialization uses the fully qualified class name as the class discriminator value for polymorphic subclasses in both closed and open polymorphic hierarchies. This value can change if you refactor the class.

To keep the class discriminator value stable, define a custom serial name with the `@SerialName` annotation.

> Each serializable class must have a unique `@SerialName`. Don't reuse the same name for different classes, even across separate polymorphic hierarchies.
>
> If you reuse the same name within the same hierarchy, encoding or decoding functions throw an `IllegalStateException`. Reusing the same name across separate hierarchies can lead to subtle serialization issues.

Use `@SerialName` to define a stable identifier for a subclass that doesn't depend on its source code:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
sealed class Project {
    abstract val name: String
}

// Assigns a custom serial name to the subclass
@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")
    println(Json.encodeToString(data))
    // {"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

Base class properties with backing fields

In a polymorphic class hierarchy, the base class can define properties with backing fields that are serialized together with subclass properties, for example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

@Serializable
sealed class Project {
    abstract val name: String
    var status = "open"
}

@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    // Configures a Json instance to encode default values
    val json = Json { encodeDefaults = true }

    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")
    // Serializes base class properties together with subclass properties
    println(json.encodeToString(data))
    // {"type":"owned","status":"open","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

Serialize objects in polymorphic class hierarchies

A polymorphic class hierarchy can have objects as subclasses. During serialization, an object is treated similarly to a class without properties, and its class name is used as the value of the `type` property by default.

To include these objects in serialization, annotate them with `@Serializable`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*

// Defines a sealed base class
@Serializable
sealed class Response

// Defines an object subclass
@Serializable
object EmptyResponse : Response()

// Defines a class that extends Response
@Serializable
class TextResponse(val text: String) : Response()

// Serializes a list containing different subclasses
fun main() {
    val list = listOf(EmptyResponse, TextResponse("OK"))
    println(Json.encodeToString(list))
    // [{"type":"EmptyResponse"},{"type":"TextResponse","text":"OK"}]
}
```

Serialize open polymorphic classes

Kotlin serialization supports open polymorphism for `open` and `abstract` classes and interfaces. In this model, subclasses can be defined anywhere in the codebase, even in other modules. Since the compiler can't determine all subclasses at compile time, you must specify them explicitly.

Use open polymorphism when not all subclasses are known at compile time. To register all subclasses at runtime, you have to specify the base type and every subclass in a `SerializersModule` class:

1. Create a `SerializersModule` with the `SerializersModule()` builder function.
2. Inside the `SerializersModule`, use the `polymorphic()` function to specify the base type.
3. Inside the `polymorphic()` block, *register* each subclass using the `subclass()` function. Registering a subclass adds it to the set of subclasses associated with the base type, which makes it available for polymorphic serialization and deserialization.
4. Add the `SerializersModule` to a `Json` instance with the `serializersModule` property.
5. Optionally, use the `@SerialName` annotation to define a stable identifier for a subclass instead of using its fully qualified class name.

To include the `type` property, use the base type as the static type, for example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

// Defines a SerializersModule
val module = SerializersModule {

    // Specifies Project as the base type
    polymorphic(Project::class) {

        // Registers OwnedProject as a subclass of Project
        subclass(OwnedProject::class)
    }
}

// Adds the SerializersModule to a Json instance
val format = Json { serializersModule = module }

// Defines the base type used as the static type during serialization
@Serializable
abstract class Project {
    abstract val name: String
}

// Defines a serializable subclass of Project
@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    // Uses Project as the static type to make use of polymorphism
    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")

    println(format.encodeToString(data))
    // {"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

This configuration produces the same JSON structure as the example in the Serialize closed polymorphic classes section, but it supports `open` and `abstract` classes.

> This example works only on the JVM because of `serializer()` function restrictions. In Kotlin/JS and Kotlin/Native, use an explicit serializer: `format.encodeToString(PolymorphicSerializer(Project::class), data)`.
>
> You can keep track of this issue on GitHub.

Serialize interfaces in open polymorphic hierarchies

You can't annotate interfaces with `@Serializable`. Kotlin serialization treats interfaces as polymorphic, using `PolymorphicSerializer` as their serializer by default.

To use an interface as the base type in open polymorphic serialization, mark the classes that implement it with `@Serializable` and register them in a `SerializersModule`:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

// Defines a SerializersModule
val module = SerializersModule {
    polymorphic(Project::class) {
        subclass(OwnedProject::class)
    }
}

val format = Json { serializersModule = module }

// Defines an interface for polymorphic serialization
interface Project {
    val name: String
}

// OwnedProject implements the Project interface
@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project

fun main() {
    // Uses the interface for serialization
    val data: Project = OwnedProject("kotlinx.coroutines", "kotlin")
    println(format.encodeToString(data))
    // {"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

> In Kotlin/JS and Kotlin/Native, you must explicitly specify the serializer with `format.encodeToString(PolymorphicSerializer(Project::class), data)` because of the platform's limited reflection capabilities.

You can also use an interface as a property in a serializable class. In this case, Kotlin serialization also applies `PolymorphicSerializer` to that property:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

val module = SerializersModule {
    polymorphic(Project::class) {
        subclass(OwnedProject::class)
    }
}

val format = Json { serializersModule = module }

interface Project {
    val name: String
}

@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project

// Defines a serializable class with an interface property
@Serializable
class Data(val project: Project)

fun main() {
    val data = Data(OwnedProject("kotlinx.coroutines", "kotlin"))
    println(format.encodeToString(data))
    // {"project":{"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}}
}
```

Select the base type of a polymorphic hierarchy

Kotlin serialization is fully static. It determines the base type of a polymorphic hierarchy at compile time. You can select any base type, including `Any`, as long as you configure it explicitly.

To do so:

1. Specify the base type and its subclasses in a `SerializersModule`.
2. If the base type doesn't have its own serializer, pass `PolymorphicSerializer` for that type when calling the `encodeToString()` function.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

val module = SerializersModule {
    // Registers OwnedProject for the Any base type
    polymorphic(Any::class) {
        subclass(OwnedProject::class)
    }
}

val format = Json { serializersModule = module }

@Serializable
abstract class Project {
    abstract val name: String
}

@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project()

fun main() {
    // Uses Any as the static type
    val data: Any = OwnedProject("kotlinx.coroutines", "kotlin")

    // Specifies a PolymorphicSerializer for the Any base type
    println(format.encodeToString(PolymorphicSerializer(Any::class), data))
    // {"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}
}
```

If you don't provide a `PolymorphicSerializer`, the following exception is thrown:

```
Exception in thread "main" kotlinx.serialization.SerializationException: Serializer for class 'Any' is
not found.
Please ensure that class is marked as '@Serializable' and that the serialization compiler plugin is
applied.
```

You can also use multiple base types for the same subclass, as long as you register the subclass for each base type explicitly.

To avoid repeating `subclass()` calls for each base type, you can define a helper function that registers the subclasses and use it in each `polymorphic()` block.

Here's an example that uses both `Project` and `BaseProject` as base types:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

val module = SerializersModule {
    // Defines a helper function that registers subclasses
    fun PolymorphicModuleBuilder<Project>.registerProjectSubclasses() {
        subclass(OwnedProject::class)
    }

    // Registers the same subclass for each base type Project and  BaseProject
    polymorphic(BaseProject::class) { registerProjectSubclasses() }
    polymorphic(Project::class) { registerProjectSubclasses() }
}

val format = Json { serializersModule = module }

interface BaseProject {
    val name: String
}

interface Project : BaseProject

@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project

@Serializable
class Data(
    val project: Project,
    val baseProject: BaseProject
)

fun main() {
    val project = OwnedProject("kotlinx.coroutines", "kotlin")
    val data = Data(project, project)
    println(format.encodeToString(data))
    // {"project":{"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"},"baseProject":
{"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}}
}
```

Serialize properties polymorphically

Interfaces and abstract classes use polymorphic serialization by default.

To serialize a property with a non-serializable type, such as `Any`, or when the property's type is an `open` class, annotate the property with `@Polymorphic`.

This applies `PolymorphicSerializer` to the property.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

val module = SerializersModule {
    polymorphic(Any::class) {
        subclass(OwnedProject::class)
    }
}

val format = Json { serializersModule = module }

interface Project {
    val name: String
}

@Serializable
@SerialName("owned")
class OwnedProject(override val name: String, val owner: String) : Project

@Serializable
class Data(
    // Applies PolymorphicSerializer to the property
    @Polymorphic
    val project: Any
)

fun main() {
    val data = Data(OwnedProject("kotlinx.coroutines", "kotlin"))
    println(format.encodeToString(data))
    // {"project":{"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}}
}
```

Serialize open classes polymorphically

To serialize an `open` class polymorphically, annotate it with both `@Serializable` and `@Polymorphic`:

```kotlin
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

val module = SerializersModule {
    polymorphic(Project::class) {
        subclass(OwnedProject::class)
    }
}

val format = Json { serializersModule = module }

// Applies PolymorphicSerializer to the open class
@Serializable
@Polymorphic
open class Project

@Serializable
@SerialName("owned")
class OwnedProject(val name: String, val owner: String) : Project()

@Serializable
class Data(val project: Project)

fun main() {
    val project = OwnedProject("kotlinx.coroutines", "kotlin")

    val data = Data(project)
    println(format.encodeToString(data))
    // {"project":{"type":"owned","name":"kotlinx.coroutines","owner":"kotlin"}}
}
```

Experimental

Register implementations of a sealed class or interface

You can combine open and closed polymorphism in the same hierarchy, for example when the root of the hierarchy is an `interface` and various sub-hierarchies are represented as sealed classes. Instead of registering each sealed subclass individually, you can register all implementations of a sealed class or interface with the `subclassesOfSealed()` function.

This function also registers subclasses recursively when a subclass is itself a sealed serializable class. All subclasses of that sealed class or interface must be either concrete or sealed. Otherwise, an `IllegalArgumentException` is thrown.

Here's an example:

```kotlin
@file:OptIn(ExperimentalSerializationApi::class)

// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

interface Base

@Serializable
sealed interface Sub: Base

@Serializable
class Sub1(val data: String): Sub

val module1 = SerializersModule {
    polymorphic(Base::class) {
        subclassesOfSealed(Sub.serializer())
    }
}

val format1 = Json { serializersModule = module1 }

val module2 = SerializersModule {
    polymorphic(Base::class) {
        // Uses the reified version of subclassesOfSealed() to specify the same sealed type
        subclassesOfSealed<Sub>()
    }
}

val format2 = Json { serializersModule = module2 }

fun main() {
    val data: Base = Sub1("kotlin")
    println(format1.encodeToString(data))
    // {"type":"Sub1","data":"kotlin"}

    println(format2.encodeToString(data))
    // {"type":"Sub1","data":"kotlin"}
}
```

Serialize generic subtypes in a polymorphic hierarchy

Kotlin serialization can't automatically determine the concrete type of a generic type parameter at runtime. As a result, it can't pick a serializer for that parameter without explicit configuration.

To provide this configuration for a generic polymorphic subtype, register the subtype in a `SerializersModule` with an explicit serializer. `PolymorphicSerializer(Any::class)` has the broadest scope, but you can use a more specific serializer when you know which concrete types the generic value can have.

> Sealed base types don't need this configuration because the compiler plugin can infer the subtype serializer when the base type provides the serializer for its type argument.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

@Serializable
abstract class Response<out T>

// Defines a generic polymorphic subtype
@Serializable
@SerialName("OkResponse")
data class OkResponse<out T>(val data: T) : Response<T>()

@Serializable
abstract class Project {
    abstract val name: String
}

// Defines a subtype used as a generic value
@Serializable
@SerialName("OwnedProject")
data class OwnedProject(override val name: String, val owner: String) : Project()

// Defines serializers for a polymorphic hierarchy with generic subtypes
val responseModule = SerializersModule {
    polymorphic(Response::class) {
        // Registers the generic subtype
        // with a serializer that specifies a PolymorphicSerializer
        subclass(OkResponse.serializer(PolymorphicSerializer(Any::class)))
    }
    polymorphic(Any::class) {
        // Registers the subtype used as the generic value
        subclass(OwnedProject::class)
    }
    polymorphic(Project::class) {
        // Registers the same subtype for the static base type
        subclass(OwnedProject::class)
    }
}

// Creates a Json instance with the registered serializers
val format = Json { serializersModule = responseModule }

fun main() {
    // Uses a generic polymorphic type with a concrete subtype
    val data: Response<Project> = OkResponse(OwnedProject("kotlinx.serialization", "kotlin"))

    val jsonString = format.encodeToString(data)
    println(jsonString)
    // {"type":"OkResponse","data":
{"type":"OwnedProject","name":"kotlinx.serialization","owner":"kotlin"}}

    val deserializedData = format.decodeFromString<Response<Project>>(jsonString)
    println(deserializedData)
    // OkResponse(data=OwnedProject(name=kotlinx.serialization, owner=kotlin))
}
```

In this example, `PolymorphicSerializer(Any::class)` allows the generic subtype `OkResponse` to be serialized with any value that's registered polymorphically as a subtype of `Any`.

Merge multiple `SerializersModule` instances

As an application grows and splits into multiple source code modules, managing all class hierarchies within a single `SerializersModule` can become difficult.

You can merge multiple `SerializersModule` instances using the `plus` operator, allowing them to be used together in the same `Json` format instance.

Here's an example:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

@Serializable
abstract class Response<out T>

@Serializable
data class OkResponse<out T>(val data: T) : Response<T>()

val responseModule = SerializersModule {
    polymorphic(Response::class) {
        subclass(OkResponse.serializer(PolymorphicSerializer(Any::class)))
    }
}

@Serializable
abstract class Project {
   abstract val name: String
}

@Serializable
data class OwnedProject(override val name: String, val owner: String) : Project()

val projectModule = SerializersModule {
    fun PolymorphicModuleBuilder<Project>.registerProjectSubclasses() {
        subclass(OwnedProject::class)
    }
    polymorphic(Any::class) { registerProjectSubclasses() }
    polymorphic(Project::class) { registerProjectSubclasses() }
}
// Merges the SerializersModule instances from both hierarchies
val format = Json { serializersModule = projectModule + responseModule }

fun main() {
    val data: Response<Project> = OkResponse(OwnedProject("kotlinx.serialization", "kotlin"))
    val string = format.encodeToString(data)
    println(string)
    // {"type":"OkResponse","data":
{"type":"OwnedProject","name":"kotlinx.serialization","owner":"kotlin"}}

    println(format.decodeFromString<Response<Project>>(string))
    // OkResponse(data=OwnedProject(name=kotlinx.serialization, owner=kotlin))
}
```

To merge modules inside a `SerializersModule` block, use the `include()` function:

```
// Merges multiple SerializersModule instances using include()
val combinedModule = SerializersModule {
    include(projectModule)
    include(responseModule)
}
```

If you expose the `SerializersModule` of your library or shared module, consumers can merge it with their own `SerializersModule`.

Deserialize unknown polymorphic subtypes with a default deserializer

When deserializing polymorphic data, Kotlin serialization resolves the subtype from the `type` property. If the subtype isn't registered, deserialization fails with a `SerializationException`.

You can define a default deserializer to handle unregistered or unknown polymorphic subtypes.

Let's look at the following example where `Project` is the base type, `OwnedProject` is a registered subtype, and `BasicProject` represents unknown project subtypes:

```
@Serializable
abstract class Project {
    abstract val name: String
}

// Represents unknown project types
@Serializable
data class BasicProject(override val name: String, val type: String): Project()

@Serializable
@SerialName("OwnedProject")
data class OwnedProject(override val name: String, val owner: String) : Project()
```

To handle unknown polymorphic subtypes of `Project`, configure a default deserializer for the base type. Use the `defaultDeserializer()` function inside the `polymorphic()` block to define a fallback for these unregistered subtypes:

```
val module = SerializersModule {
    polymorphic(Project::class) {
        subclass(OwnedProject::class)
        defaultDeserializer { BasicProject.serializer() }
    }
}
```

You can use this `SerializersModule` configuration to deserialize both registered and unregistered subtypes:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.modules.*

@Serializable
abstract class Project {
    abstract val name: String
}

// Represents unknown project types
@Serializable
data class BasicProject(override val name: String, val type: String): Project()

@Serializable
@SerialName("OwnedProject")
data class OwnedProject(override val name: String, val owner: String) : Project()

// Registers a default deserializer for unknown Project subtypes
val module = SerializersModule {
    polymorphic(Project::class) {
        subclass(OwnedProject::class)
        defaultDeserializer { BasicProject.serializer() }
    }
}

val format = Json { serializersModule = module }

fun main() {
    // Deserializes both a known and an unknown Project subtype
    println(format.decodeFromString<List<Project>>("""
        [
            {"type":"unknown","name":"example"},
            {"type":"OwnedProject","name":"kotlinx.serialization","owner":"kotlin"}
        ]
    """))
    // [BasicProject(name=example, type=unknown), OwnedProject(name=kotlinx.serialization,
owner=kotlin)]
}
```

In this example, deserialization doesn't rely on the `type` field to differentiate subtypes and instead uses the plugin-generated serializer for `BasicProject`. This approach assumes that unknown subtypes follow a known structure.

For JSON, you can also configure the format to ignore unknown keys when unknown subtypes contain extra properties but still match the structure expected by the default deserializer. If unknown input varies in structure, use a custom serializer instead.

> For more flexible handling of JSON input during deserialization, see Modify JSON structure.

Serialize polymorphic types with a default serializer

You can serialize values of a polymorphic base type without registering every concrete subtype. Use this when you don't have access to the full type hierarchy, or when it changes a lot.

To do so:

1. Use the `polymorphicDefaultSerializer()` function in a `SerializersModule` block.

2. Specify a lambda in `polymorphicDefaultSerializer()` that returns a `SerializationStrategy` for the runtime value.

Let's look at an example with two private classes, `CatImpl` and `DogImpl`. To avoid raising their visibility, register a default serializer for `Animal` that selects a serializer based on the runtime type through public interfaces:

```
interface Animal

interface Cat : Animal {
    val catType: String
}

interface Dog : Animal {
    val dogType: String
}

private class CatImpl : Cat {
    override val catType: String = "Tabby"
}

private class DogImpl : Dog {
    override val dogType: String = "Husky"
}

object AnimalProvider {
    fun createCat(): Cat = CatImpl()
    fun createDog(): Dog = DogImpl()
}

// Registers a default serializer for unknown Animal subtypes
val module = SerializersModule {
    polymorphicDefaultSerializer(Animal::class) { instance ->
        @Suppress("UNCHECKED_CAST")
        // Determines the appropriate serializer using a when block
        when (instance) {
            is Cat -> CatSerializer as SerializationStrategy<Animal>
            is Dog -> DogSerializer as SerializationStrategy<Animal>
            else -> null
        }
    }
}
```

Define serializers for `Cat` and `Dog`, then create a `Json` instance that uses the `SerializersModule` with the `serializersModule` property to enable polymorphic serialization of `Animal` values:

```
// Imports declarations from the serialization library
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.modules.*

interface Animal

interface Cat : Animal {
    val catType: String
}

interface Dog : Animal {
    val dogType: String
}

private class CatImpl : Cat {
    override val catType: String = "Tabby"
}

private class DogImpl : Dog {
    override val dogType: String = "Husky"
}

object AnimalProvider {
    fun createCat(): Cat = CatImpl()
    fun createDog(): Dog = DogImpl()
}

// Registers a default serializer for unknown Animal subtypes
val module = SerializersModule {
    polymorphicDefaultSerializer(Animal::class) { instance ->
        @Suppress("UNCHECKED_CAST")
        // Determines the appropriate serializer using a when block based on the runtime value
        when (instance) {
            is Cat -> CatSerializer as SerializationStrategy<Animal>
            is Dog -> DogSerializer as SerializationStrategy<Animal>
            else -> null
        }
    }
}

// Defines custom serializers
object CatSerializer : SerializationStrategy<Cat> {
    override val descriptor = buildClassSerialDescriptor("Cat") {
        element<String>("catType")
    }

    override fun serialize(encoder: Encoder, value: Cat) {
        encoder.encodeStructure(descriptor) {
            encodeStringElement(descriptor, 0, value.catType)
        }
    }
}

object DogSerializer : SerializationStrategy<Dog> {
    override val descriptor = buildClassSerialDescriptor("Dog") {
        element<String>("dogType")
    }

    override fun serialize(encoder: Encoder, value: Dog) {
        encoder.encodeStructure(descriptor) {
```

```
            encodeStringElement(descriptor, 0, value.dogType)
        }
    }
}

val format = Json { serializersModule = module }

fun main() {
    // Serializes an instance of Cat
    println(format.encodeToString<Animal>(AnimalProvider.createCat()))
    // {"type":"Cat","catType":"Tabby"}
}
```

What's next

- Learn how to obtain generated serializers, create custom serializers, and apply serializers in Create and use serializers.

Create and use serializers

A serializer defines the structure of a Kotlin type in its serialized form, while format implementations such as `Json` control how that structure is encoded.

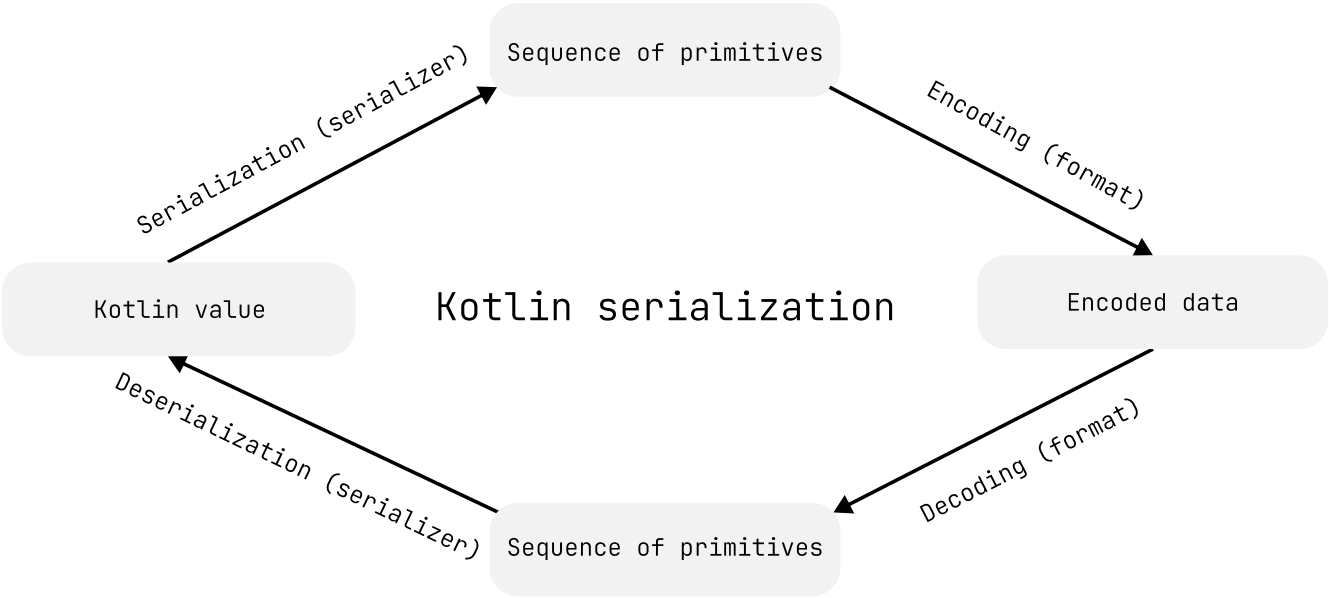


Diagram where a Kotlin value is serialized by a serializer into a sequence of primitives, encoded by a format into encoded data, decoded back into a sequence of primitives, and deserialized by a serializer into a Kotlin value

Serializers define serialization and deserialization strategies for a type through the `KSerializer` interface. Kotlin serialization provides serializers for built-in types, collections, and more.

You can use these serializers to serialize values or inspect the structure of their serialized form, while custom serializers let you define that structure yourself.

Obtain serializers

When you annotate a class with `@Serializable`, the Kotlin serialization plugin generates a `KSerializer` for that class.

To retrieve this automatically generated serializer, call the generated `.serializer()` function. You can use a serializer directly with functions such as `Json.encodeToString()`, or access its `descriptor` property to inspect the structure of the type's serialized form.

Here's an example that defines a `Color` class with a single integer property and inspects the structure of its serialized form:

```
import kotlinx.serialization.*

@Serializable
data class Color(val rgb: Int)

fun main() {
    // Retrieves the generated serializer for the Color class
    val colorSerializer: KSerializer<Color> = Color.serializer()

    println(colorSerializer.descriptor)
    // Color(rgb: kotlin.Int)
}
```

Built-in primitive types and `String` also provide serializers through the `.serializer()` function, such as `Int.serializer()` and `String.serializer()`.

You can use the top-level `serializer<T>()` function to obtain a serializer for any type, including parameterized ones:

```
import kotlinx.serialization.*

@Serializable
@SerialName("Color")
class Color(val rgb: Int)

fun main() {
    // Retrieves the serializer for the Map<String, Color>
    val stringToColorMapSerializer: KSerializer<Map<String, Color>> = serializer()

    // Prints: kotlin.collections.LinkedHashMap(PrimitiveDescriptor(kotlin.String), Color(rgb:
kotlin.Int))
    println(stringToColorMapSerializer.descriptor)
}
```

For generic classes, if you want to use the generated `.serializer()` function, provide one `KSerializer` argument for each type parameter:

```
import kotlinx.serialization.*

@Serializable
@SerialName("Color")
class Color(val rgb: Int)

@Serializable
@SerialName("Box")
class Box<T>(val contents: T)

fun main() {
    // Calls .serializer() using a KSerializer for the type parameter
    val boxedColorSerializer = Box.serializer(Color.serializer())

    println(boxedColorSerializer.descriptor)
    // Box(contents: Color)
}
```

Obtain serializers for collection types

Unlike classes annotated with `@Serializable`, collection types like `List<T>` don't have a generated `.serializer()` function.

To obtain a serializer for a collection type, create one with `ListSerializer()`, `SetSerializer()`, or `MapSerializer()` and specify serializers for the collection's type parameters.

Here's an example that uses the `ListSerializer()` function to create a serializer for `List<String>`:

```
import kotlinx.serialization.*
import kotlinx.serialization.builtins.*

fun main() {
    val stringListSerializer: KSerializer<List<String>> = ListSerializer(String.serializer())
    println(stringListSerializer.descriptor)
    // kotlin.collections.ArrayList(PrimitiveDescriptor(kotlin.String))
}
```

Create custom serializers

If you want more control over the structure of your serialized data, you can create a custom serializer. A custom serializer lets you define how a type is represented in its serialized form.

Like generated serializers, custom serializers define both serialization and deserialization for a type through the `KSerializer` interface. To support both, `KSerializer` extends `SerializationStrategy` and `DeserializationStrategy`.

> For JSON serialization, you can also modify the JSON output produced by an existing serializer without redefining its structure with `JsonTransformingSerializer`.

Create a custom primitive serializer

Use a primitive serializer to represent a class as a single primitive value, such as a string or integer.

To create a custom primitive serializer:

1. Create a custom serializer as an `object` that implements `KSerializer` for the serialized class:

```
object YourSerializer : KSerializer<Type>
```

2. Override the `descriptor` property to define the schema for the serialized data.

   Use the `PrimitiveSerialDescriptor(serialName, kind)` to define the structure of the serialized form as a single primitive value. Specify a **unique** `serialName`, such as a fully qualified name, and use a `PrimitiveKind` that matches the encoder and decoder functions used in the serializer:

```
override val descriptor: SerialDescriptor =
    PrimitiveSerialDescriptor("com.example.Type", PrimitiveKind.STRING)
```

   If the `descriptor` doesn't match the encoding and decoding functions, updates to `kotlinx.serialization` may cause the serializer to behave unpredictably in some formats.

3. Implement the `serialize()` function to define how values are converted to their serialized form. Choose an `Encoder` function that matches the `PrimitiveKind` in the `descriptor`:

```
override fun serialize(encoder: Encoder, value: Type) {
    val encodedValue: String = // convert value to a primitive representation
    encoder.encodeString(encodedValue)
}
```

4. Implement the `deserialize()` function to define how to convert the serialized data back into an instance of your class. The `Decoder` provides functions to read the data, such as `decodeString()`.

```
override fun deserialize(decoder: Decoder): Type {
    val decodedValue: String = decoder.decodeString()
    // Converts decodedValue back to Type
    return ...
}
```

5. Use the `@Serializable` annotation to specify a custom serializer for the class:

```
@Serializable(YourSerializer::class)
data class Type(val stringValue: String)
```

Here's an example for a custom primitive serializer that serializes `Color` as a hexadecimal string:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*

// Creates the custom serializer for the Color class
object ColorAsStringSerializer : KSerializer<Color> {
    // Defines the schema for the serialized data as a single string
    override val descriptor: SerialDescriptor =
        // Specifies a unique name and a PrimitiveKind
        PrimitiveSerialDescriptor("my.app.Color", PrimitiveKind.STRING)

    // Defines how a Color value is serialized as a string
    override fun serialize(encoder: Encoder, value: Color) {
        // Converts the RGB value to a hexadecimal string
        val hexValue = value.rgb.toString(16).padStart(6, '0')
        // Encodes the serialized value as a string
        encoder.encodeString(hexValue)
    }

    // Defines how a Color value is deserialized from a string
    override fun deserialize(decoder: Decoder): Color {
        // Decodes the serialized string value
        val hexValue = decoder.decodeString()
        // Converts the decoded value back into a Color
        return Color(hexValue.toInt(16))
    }
}
// Specifies ColorAsStringSerializer as the custom serializer for the Color class
@Serializable(ColorAsStringSerializer::class)
data class Color(val rgb: Int)

fun main() {
    val color = Color(0x00FF00)
    // Serializes a Color value to JSON
    val jsonString = Json.encodeToString(color)

    println(jsonString)
    // "00ff00"

    // Deserializes the JSON string into a Color value
    val deserializedColor = Json.decodeFromString<Color>(jsonString)

    println(deserializedColor.rgb)
    // 65280
}
```

Serialize binary data as Base64 strings

You can use a custom primitive serializer to solve common serialization tasks beyond simple value conversion. One such task is representing binary data as a Base64 string.

Different APIs use different Base64 variants by default. Choose a Kotlin Base64 encoder that matches the expected variant, such as `Base64.Default` or `Base64.Mime`.

Here's an example that serializes a `ByteArray` as a Base64 string with `Base64.Default` in JSON format:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.encoding.Encoder
import kotlinx.serialization.encoding.Decoder
import kotlinx.serialization.descriptors.*
import kotlin.io.encoding.*

// Creates a custom primitive serializer,
// which represents ByteArray as a Base64 string
object ByteArrayAsBase64Serializer : KSerializer<ByteArray> {

    // Uses the default Base64 variant
    private val base64 = Base64.Default

    // Defines the serialized form as a single STRING primitive
    override val descriptor: SerialDescriptor
        get() = PrimitiveSerialDescriptor(
            "ByteArrayAsBase64Serializer",
            PrimitiveKind.STRING
        )

    // Encodes the ByteArray as a Base64 string
    override fun serialize(encoder: Encoder, value: ByteArray) {
        val base64Encoded = base64.encode(value)
        encoder.encodeString(base64Encoded)
    }

    // Decodes the Base64 string back into a ByteArray
    override fun deserialize(decoder: Decoder): ByteArray {
        val base64Decoded = decoder.decodeString()
        return base64.decode(base64Decoded)
    }
}

@Serializable
data class Value(
    // Specifies the custom serializer for this property
    @Serializable(ByteArrayAsBase64Serializer::class)
    val base64Input: ByteArray
) {

    // Implements value-based equality for ByteArray
    override fun equals(other: Any?): Boolean {
        if (this === other) return true
        if (javaClass ≠ other?.javaClass) return false
        other as Value
        return base64Input.contentEquals(other.base64Input)
    }

    // Computes hashCode based on array contents
    override fun hashCode(): Int {
        return base64Input.contentHashCode()
    }
}

fun main() {
    val string = "PNG_IMAGE_DATA"
    val value = Value(string.toByteArray())

    // Serializes Value to JSON
    val encoded = Json.encodeToString(value)

    println(encoded)
```

```
    // {"base64Input":"UE5HX0lNQUdFX0RBVEE="}

    // Deserializes JSON back into Value
    val decoded = Json.decodeFromString<Value>(encoded)

    println(decoded.base64Input.decodeToString())
    // PNG_IMAGE_DATA
}
```

Delegate serialization to another serializer

You can serialize a class as another type by delegating the serialization logic to the serializer for that type. For example, you can use this approach to serialize a class as a non-primitive type, such as an `IntArray`.

To delegate serialization, create a custom serializer that defines a property for the serializer of the delegated type:

1. Override the `descriptor` property to wrap the delegated serializer's `descriptor`.

   > When you delegate serialization, you can't use the original class `descriptor` or the delegated type's `descriptor` directly. Instead, create a new `descriptor` that reuses the delegated serializer's structure.

2. Override the `serialize()` function to convert an instance of your class to the delegated type and use `encoder.encodeSerializableValue()` function to encode it with the delegated serializer.
3. Override the `deserialize()` function to use the `decoder.decodeSerializableValue()` function with the delegated serializer to decode the value and convert it back into an instance of your class.

Here's an example that serializes a `Color` class as an `IntArray` by delegating the serialization logic to `IntArraySerializer`:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.builtins.IntArraySerializer
import kotlinx.serialization.json.*

// Creates a custom serializer that delegates to IntArraySerializer
class ColorIntArraySerializer : KSerializer<Color> {
    private val delegateSerializer = IntArraySerializer()
    override val descriptor = SerialDescriptor("my.app.Color", delegateSerializer.descriptor)

    // Delegates serialization logic to IntArraySerializer
    override fun serialize(encoder: Encoder, value: Color) {
        val data = intArrayOf(
            (value.rgb shr 16) and 0xFF,
            (value.rgb shr 8) and 0xFF,
            value.rgb and 0xFF
        )
        encoder.encodeSerializableValue(delegateSerializer, data)
    }

    // Delegates deserialization and converts IntArray back to Color
    override fun deserialize(decoder: Decoder): Color {
        val array = decoder.decodeSerializableValue(delegateSerializer)
        return Color((array[0] shl 16) or (array[1] shl 8) or array[2])
    }
}

@Serializable(ColorIntArraySerializer::class)
class Color(val rgb: Int)

fun main() {
    val green = Color(0x00ff00)

    println(Json.encodeToString(green))
    // [0,255,0]
}
```

While using the array representation isn't conventional in JSON, it can reduce the size of serialized data when used with a `ByteArray` and a binary format.

> For more information on how non-JSON serialization formats treat arrays, see Alternative and custom serialization formats.

Serialize classes with a surrogate class

You can use a *surrogate class*, a class that matches the serialized form of another class, when you want to:

- Change how a class is serialized without modifying the class itself.
- Avoid creating a composite serializer.
- Validate the serialized form before creating the original class.
- Handle cases where direct serialization doesn't fit the class's rules.

You can make surrogate classes `private`, and use an `init` block to enforce constraints on the serial representation of the class. You can also define a custom serial name to keep the serialized type name unchanged.

Let's look at an example that serializes `Color` as a JSON object with specific ranges for the `r`, `g`, and `b` properties:

```
// Defines a surrogate that matches the serialized form
@Serializable
@SerialName("Color")
private class ColorSurrogate(val r: Int, val g: Int, val b: Int) {
    init {
        // Enforces constraints on the serialized form
        require(r in 0..255 && g in 0..255 && b in 0..255)
    }
}
```

Similarly to delegating serialization to another serializer, the custom serializer converts the original class to another representation and wraps that representation's automatically generated `SerialDescriptor`.

> Surrogate classes define a `SerialDescriptor` with their own `serialName`. You can reuse the structure of the surrogate class's `SerialDescriptor`, but not its `serialName`, because each `SerialDescriptor` must have a unique `serialName`.

To retrieve the generated serializer for the surrogate class, use `ColorSurrogate.serializer()`:

```
object ColorSerializer : KSerializer<Color> {
    // The serialNames of descriptors must be unique
    override val descriptor: SerialDescriptor = SerialDescriptor("my.app.Color",
ColorSurrogate.serializer().descriptor)

    // Converts the original class to the surrogate representation
    override fun serialize(encoder: Encoder, value: Color) {
        val surrogate = ColorSurrogate((value.rgb shr 16) and 0xff, (value.rgb shr 8) and 0xff,
value.rgb and 0xff)
        encoder.encodeSerializableValue(ColorSurrogate.serializer(), surrogate)
    }

    // Converts the surrogate representation back to the original class
    override fun deserialize(decoder: Decoder): Color {
        val surrogate = decoder.decodeSerializableValue(ColorSurrogate.serializer())
        return Color((surrogate.r shl 16) or (surrogate.g shl 8) or surrogate.b)
    }
}
```

Finally, specify the custom serializer for the class:

```kotlin
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.builtins.IntArraySerializer
import kotlinx.serialization.json.*

// Defines a private surrogate class with custom properties
@Serializable
@SerialName("Color")
private class ColorSurrogate(val r: Int, val g: Int, val b: Int) {
    init {
        // Enforces constraints on the serialized form
        require(r in 0..255 && g in 0..255 && b in 0..255)
    }
}

// Creates a custom serializer that converts to and from the surrogate
object ColorSerializer : KSerializer<Color> {
    // Defines a unique serialName for the wrapped SerialDescriptor
    override val descriptor: SerialDescriptor =
        SerialDescriptor("my.app.Color", ColorSurrogate.serializer().descriptor)

    // Converts the original class to the surrogate representation
    override fun serialize(encoder: Encoder, value: Color) {
        val surrogate = ColorSurrogate((value.rgb shr 16) and 0xff, (value.rgb shr 8) and 0xff,
value.rgb and 0xff)
        encoder.encodeSerializableValue(ColorSurrogate.serializer(), surrogate)
    }

    // Converts the surrogate representation back to the original class
    override fun deserialize(decoder: Decoder): Color {
        val surrogate = decoder.decodeSerializableValue(ColorSurrogate.serializer())
        return Color((surrogate.r shl 16) or (surrogate.g shl 8) or surrogate.b)
    }
}

// Specifies ColorSerializer as the custom serializer for the class
@Serializable(ColorSerializer::class)
class Color(val rgb: Int)

fun main() {
    val green = Color(0x00ff00)

    println(Json.encodeToString(green))
    // {"r":0,"g":255,"b":0}
}
```

Create a custom composite serializer

You can use composite serializers to represent complex data structures, such as classes with multiple properties.

Compared to using a surrogate class, a custom composite serializer lets you define the serialized structure of the original class directly without an additional conversion step. This can also improve performance in some cases, but requires writing more of the serialization logic manually.

To create a custom composite serializer:

1. Create a serializer as an `object` that implements `KSerializer` for the target class:

```kotlin
object YourSerializer : KSerializer<Type>
```

2. Override the `descriptor` property and define the serialization schema with the `buildClassSerialDescriptor()` function:

```
override val descriptor: SerialDescriptor =
    buildClassSerialDescriptor("com.example.Type") {
        // ...
    }
```

3. Specify each property in the `buildClassSerialDescriptor()` function with the `element()` function. The order of elements determines their indices, starting from `0`.

   The `SerialKind` of the serializer's `descriptor` determines what each `element()` represents. In a class `descriptor`, an `element()` represents a property, while in an enum `descriptor`, an `element()` represents constants such as `RED` or `GREEN`:

```
override val descriptor: SerialDescriptor =
    buildClassSerialDescriptor("com.example.Type") {
        element<Int>("first")
        element<Int>("second")
    }
```

4. Implement the `serialize()` function using the `encodeStructure()` DSL. Inside its block, the lambda receiver is a `CompositeEncoder`, which you use to call functions such as `encodeIntElement()` for each field, following the order defined in the `descriptor`:

```
override fun serialize(encoder: Encoder, value: Type) =
    encoder.encodeStructure(descriptor) {
        encodeIntElement(descriptor, 0, value.first)
        encodeIntElement(descriptor, 1, value.second)
    }
```

5. Implement the `deserialize()` function using the `decodeStructure()` DSL. Inside its block, the lambda receiver is a `CompositeDecoder`, which you use to call functions like `decodeIntElement()` to decode each property.

   Most formats allow data to be encoded in an arbitrary order, which can differ from the order of elements in the serializer's `descriptor`. Use the `decodeElementIndex()` function to identify which `element()` to decode. It returns `CompositeDecoder.DECODE_DONE` when no more elements are left, which you use to stop decoding the current structure:

```
override fun deserialize(decoder: Decoder): Type =
    decoder.decodeStructure(descriptor) {
        var first = 0
        var second = ""

        // Uses decodeElementIndex to ensure correct decoding regardless of order
        while (true) {
            when (val index = decodeElementIndex(descriptor)) {
                0 -> first = decodeStringElement(descriptor, 0)
                1 -> second = decodeIntElement(descriptor, 1)
                CompositeDecoder.DECODE_DONE -> break
                else -> error("Unexpected index: $index")
            }
        }

        Type(first, second)
    }
```

6. Use the `@Serializable(YourSerializer::class)` annotation to specify the custom serializer for the class.

> If you only need to transform or restructure data without manually handling each element, consider delegating serialization to another serializer or a surrogate class for a simpler approach.

Let's look at an example of how to serialize a `Color` class with multiple properties:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*

// Creates a custom serializer for the Color class with multiple properties
object ColorAsObjectSerializer : KSerializer<Color> {
    // Defines the schema for the Color class
    override val descriptor: SerialDescriptor =
        buildClassSerialDescriptor("my.app.Color") {
            // Specifies each property with its type and name with the element() function
            element<Int>("r")
            element<Int>("g")
            element<Int>("b")
        }

    // Serializes the Color in the order specified in the descriptor
    override fun serialize(encoder: Encoder, value: Color) =
        encoder.encodeStructure(descriptor) {
            encodeIntElement(descriptor, 0, (value.rgb shr 16) and 0xff)
            encodeIntElement(descriptor, 1, (value.rgb shr 8) and 0xff)
            encodeIntElement(descriptor, 2, value.rgb and 0xff)
        }

    // Deserializes the data back into a Color object
    override fun deserialize(decoder: Decoder): Color =
        decoder.decodeStructure(descriptor) {
            // Temporary variables to hold the decoded values
            var r = -1
            var g = -1
            var b = -1
            // Uses decodeElementIndex() since element order may vary by format
            while (true) {
                when (val index = decodeElementIndex(descriptor)) {
                    0 -> r = decodeIntElement(descriptor, 0)
                    1 -> g = decodeIntElement(descriptor, 1)
                    2 -> b = decodeIntElement(descriptor, 2)
                    CompositeDecoder.DECODE_DONE -> break
                    else -> error("Unexpected index: $index")
                }
            }
            // Validates values and reconstructs Color
            require(r in 0..255 && g in 0..255 && b in 0..255)
            Color((r shl 16) or (g shl 8) or b)
        }
}

// Specifies the custom serializer for Color
@Serializable(ColorAsObjectSerializer::class)
data class Color(val rgb: Int)

fun main() {
    val color = Color(0x00ff00)
    val string = Json.encodeToString(color)

    println(string)
    // {"r":0,"g":255,"b":0}

    require(Json.decodeFromString<Color>(string) == color)
}
```

Encode default values in custom serializers

Plugin-generated serializers check whether the encoder needs to encode values that are equal to their defaults. For example, in JSON, this is controlled by the `encodeDefaults` property.

To achieve the same behavior in a custom serializer, use the `shouldEncodeElementDefault()` function with the serializer's `descriptor` and the index of the element you're encoding.

> If a property is annotated with `@EncodeDefault`, plugin-generated serializers don't call `shouldEncodeElementDefault()`.

Here's an example where a custom serializer encodes default `Color` values when `encodeDefaults` is enabled:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*

// Creates a custom serializer for the Color class with multiple properties
object ColorAsObjectSerializer : KSerializer<Color> {
    // Defines the schema for the Color class
    override val descriptor: SerialDescriptor =
        buildClassSerialDescriptor("my.app.Color") {
            // Specifies each property with its type and name with the element() function
            element<Int>("r", isOptional = true)
            element<Int>("g", isOptional = true)
            element<Int>("b", isOptional = true)
        }

    override fun serialize(encoder: Encoder, value: Color) =
        encoder.encodeStructure(descriptor) {
            val r = (value.rgb shr 16) and 0xff
            val g = (value.rgb shr 8) and 0xff
            val b = value.rgb and 0xff

            // Encodes r if it differs from its default value,
            // or if the encoder needs to encode the first element's default value
            if (r != 0 || shouldEncodeElementDefault(descriptor, 0)) {
                encodeIntElement(descriptor, 0, r)
            }
            if (g != 255 || shouldEncodeElementDefault(descriptor, 1)) {
                encodeIntElement(descriptor, 1, g)
            }
            if (b != 0 || shouldEncodeElementDefault(descriptor, 2)) {
                encodeIntElement(descriptor, 2, b)
            }
        }

    // Deserializes the data back into a Color object
    override fun deserialize(decoder: Decoder): Color =
        decoder.decodeStructure(descriptor) {
            var r = 0
            var g = 255
            var b = 0

            while (true) {
                when (val index = decodeElementIndex(descriptor)) {
                    0 -> r = decodeIntElement(descriptor, 0)
                    1 -> g = decodeIntElement(descriptor, 1)
                    2 -> b = decodeIntElement(descriptor, 2)
                    CompositeDecoder.DECODE_DONE -> break
                    else -> error("Unexpected index: $index")
                }
            }
            require(r in 0..255 && g in 0..255 && b in 0..255)
            Color((r shl 16) or (g shl 8) or b)
        }
}

// Specifies the custom serializer for Color
@Serializable(ColorAsObjectSerializer::class)
data class Color(val rgb: Int = 0x00ff00)

fun main() {
    val color = Color()
    val stringWithDefaults = Json { encodeDefaults = true }.encodeToString(color)
```

```
    println(stringWithDefaults)
    // {"r":0,"g":255,"b":0}
}
```

Experimental

Optimize deserialization with sequential decoding

Some formats use a strictly ordered schema and can support sequential decoding. For these formats, you can optimize deserialization with the `decodeSequentially()` function. This function returns `true` if the current structure can be decoded in order. Handle that case separately to skip the more complex logic of decoding individual elements out of order.

Serializers generated by the `kotlinx.serialization` plugin use this optimization.

Here's an example that uses `decodeSequentially()` to optimize deserialization when possible:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*

object ColorAsObjectSerializer : KSerializer<Color> {

    override val descriptor: SerialDescriptor =
        buildClassSerialDescriptor("my.app.Color") {
            element<Int>("r")
            element<Int>("g")
            element<Int>("b")
        }

    override fun serialize(encoder: Encoder, value: Color) =
        encoder.encodeStructure(descriptor) {
            encodeIntElement(descriptor, 0, (value.rgb shr 16) and 0xff)
            encodeIntElement(descriptor, 1, (value.rgb shr 8) and 0xff)
            encodeIntElement(descriptor, 2, value.rgb and 0xff)
        }

    override fun deserialize(decoder: Decoder): Color =
        decoder.decodeStructure(descriptor) {
            var r = -1
            var g = -1
            var b = -1
            // Decodes values directly in order if the format stores data sequentially
            @OptIn(ExperimentalSerializationApi::class)
            if (decodeSequentially()) {
                r = decodeIntElement(descriptor, 0)
                g = decodeIntElement(descriptor, 1)
                b = decodeIntElement(descriptor, 2)
            } else while (true) {
                // Ensures correct decoding for formats where elements may be unordered
                when (val index = decodeElementIndex(descriptor)) {
                    0 -> r = decodeIntElement(descriptor, 0)
                    1 -> g = decodeIntElement(descriptor, 1)
                    2 -> b = decodeIntElement(descriptor, 2)
                    CompositeDecoder.DECODE_DONE -> break
                    else -> error("Unexpected index: $index")
                }
            }
            require(r in 0..255 && g in 0..255 && b in 0..255)
            Color((r shl 16) or (g shl 8) or b)
        }
}

@Serializable(ColorAsObjectSerializer::class)
data class Color(val rgb: Int)

fun main() {
    val color = Color(0x00ff00)
    val string = Json.encodeToString(color)

    println(string)
    // {"r":0,"g":255,"b":0}

    require(Json.decodeFromString<Color>(string) == color)
}
```

Create a custom serializer for generic types

To create a custom serializer for a generic class, declare the serializer as a `class` instead of an `object`, with one `KSerializer` constructor parameter for each generic type parameter.

You can delegate the serialization logic for each type parameter to the corresponding `KSerializer`, so it's encoded according to its own serialization rules.

Let's look at an example using a generic `Box<T>` class:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*

@Serializable(BoxSerializer::class)
data class Box<T>(val contents: T)

// Creates a custom serializer as a class for Box<T>
class BoxSerializer<T>(private val dataSerializer: KSerializer<T>) : KSerializer<Box<T>> {
    // Defines a unique serialName for the Box<T> descriptor
    override val descriptor: SerialDescriptor =
        SerialDescriptor("my.app.Box", dataSerializer.descriptor)

    // Delegates serialization and deserialization
    override fun serialize(encoder: Encoder, value: Box<T>) = dataSerializer.serialize(encoder,
value.contents)
    override fun deserialize(decoder: Decoder) = Box(dataSerializer.deserialize(decoder))
}

@Serializable
data class Project(val name: String)

fun main() {
    val box = Box(Project("kotlinx.serialization"))
    val string = Json.encodeToString(box)

    println(string)
    // {"name":"kotlinx.serialization"}

    println(Json.decodeFromString<Box<Project>>(string))
    // Box(contents=Project(name=kotlinx.serialization))
}
```

Experimental

Use a plugin-generated serializer together with a custom serializer

By default, the Kotlin serialization plugin doesn't generate a serializer if you specify a custom serializer with `@Serializable(YourSerializer::class)`.

You might still want to use the plugin-generated serializer, for example:

- Using the plugin-generated serializer as a fallback strategy.
- Inspecting the plugin-generated `descriptor` to access the default structure.
- Reusing default serialization behavior in subclasses that don't use a custom serializer.

You can keep the automatically generated serializer alongside your custom one by annotating the serializable class with `@KeepGeneratedSerializer`. To access the plugin-generated serializer, use the `.generatedSerializer()` function on the companion object of the serializable class.

This can also be useful when using a `JsonTransformingSerializer` to adjust the JSON structure and reuse the plugin-generated serializer for the default serialization logic.

Here's an example that uses both a custom serializer and the plugin-generated serializer:

```
import kotlinx.serialization.*
import kotlinx.serialization.json.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*

object ColorAsStringSerializer : KSerializer<Color> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.ColorAsString",
PrimitiveKind.STRING)

    override fun serialize(encoder: Encoder, value: Color) {
        val string = value.rgb.toString(16).padStart(6, '0')
        encoder.encodeString(string)
    }

    override fun deserialize(decoder: Decoder): Color {
        val string = decoder.decodeString()
        return Color(string.toInt(16))
    }
}

@OptIn(ExperimentalSerializationApi::class)
@KeepGeneratedSerializer
@Serializable(ColorAsStringSerializer::class)
class Color(val rgb: Int)

fun main() {
    val green = Color(0x00ff00)

    // Uses the custom serializer
    println(Json.encodeToString(green))
    // "00ff00"

    // Uses the plugin-generated serializer
    println(Json.encodeToString(Color.generatedSerializer(), green))
    // {"rgb":65280}

}
```

Apply serializers

You can apply custom serializers to your own classes and to third-party types. Third-party types, such as java.util.Date, can't be directly annotated with `@Serializable` because their source code can't be modified.

Pass a serializer manually

To serialize a type with a custom serializer, create the serializer and pass it explicitly to overloads of functions such as `Json.encodeToString()` and `Json.decodeFromString()`.

Here's an example that serializes `Date` values as the number of milliseconds since the Unix epoch:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*
import java.util.Date
import java.text.SimpleDateFormat

// Can't use @Serializable on Date without access to its source code
object DateAsLongSerializer : KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.DateAsLong",
PrimitiveKind.LONG)
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeLong(value.time)
    override fun deserialize(decoder: Decoder): Date = Date(decoder.decodeLong())
}

fun main() {
    val kotlin10ReleaseDate = SimpleDateFormat("yyyy-MM-ddX").parse("2016-02-15+00")

    // Serializes Date as a Long in milliseconds
    println(Json.encodeToString(DateAsLongSerializer, kotlin10ReleaseDate))
    // 1455494400000
}
```

Specify a serializer on a property

When a type is used as a property in a serializable class, specify its custom serializer on that property with the `@Serializable` annotation:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*
import java.util.Date
import java.text.SimpleDateFormat

object DateAsLongSerializer : KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.DateAsLong",
PrimitiveKind.LONG)
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeLong(value.time)
    override fun deserialize(decoder: Decoder): Date = Date(decoder.decodeLong())
}

@Serializable
class ProgrammingLanguage(
    val name: String,
    // Specifies the custom serializer for the Date property
    @Serializable(DateAsLongSerializer::class)
    val stableReleaseDate: Date
)

fun main() {
    val data = ProgrammingLanguage("Kotlin", SimpleDateFormat("yyyy-MM-ddX").parse("2016-02-15+00"))

    println(Json.encodeToString(data))
    // {"name":"Kotlin","stableReleaseDate":1455494400000}
}
```

Specify a serializer on a type

You can also apply the `@Serializable` annotation directly to a type. You can use this to specify a custom serializer for a type when it's used as a generic type argument, for example in `List<Date>`:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*
import java.util.Date
import java.text.SimpleDateFormat

object DateAsLongSerializer : KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.DateAsLong",
PrimitiveKind.LONG)
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeLong(value.time)
    override fun deserialize(decoder: Decoder): Date = Date(decoder.decodeLong())
}

@Serializable
class ProgrammingLanguage(
    val name: String,
     // Specifies the custom serializer for Date as a generic type argument
    val releaseDates: List<@Serializable(DateAsLongSerializer::class) Date>
)

fun main() {
    val df = SimpleDateFormat("yyyy-MM-ddX")
    val data = ProgrammingLanguage("Kotlin", listOf(df.parse("2023-07-06+00"), df.parse("2023-04-
25+00"), df.parse("2022-12-28+00")))

   println(Json.encodeToString(data))
    // {"name":"Kotlin","releaseDates":[1688601600000,1682380800000,1672185600000]}
}
```

Specify a serializer for a file

To apply a serializer to all properties of a given type in a source file, add the `@UseSerializers` annotation at the beginning of the file:

```
@file:UseSerializers(DateAsLongSerializer::class)
```

This applies the `DateAsLongSerializer` to all instances of that type within the file, so you don't need to annotate each property separately.

Here's an example:

```
// Applies the custom serializer to all properties of that type in the file
@file:UseSerializers(DateAsLongSerializer::class)

import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*
import java.util.Date
import java.text.SimpleDateFormat

object DateAsLongSerializer : KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.DateAsLong",
PrimitiveKind.LONG)
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeLong(value.time)
    override fun deserialize(decoder: Decoder): Date = Date(decoder.decodeLong())
}

// Uses the file-level serializer for the Date property
@Serializable
class ProgrammingLanguage(val name: String, val stableReleaseDate: Date)

fun main() {
    val data = ProgrammingLanguage("Kotlin", SimpleDateFormat("yyyy-MM-ddX").parse("2016-02-15+00"))

   println(Json.encodeToString(data))
    // {"name":"Kotlin","stableReleaseDate":1455494400000}
}
```

Specify serializers with type aliases

In Kotlin serialization, you usually specify serialization strategies explicitly with the `@Serializable` annotation. It doesn't provide a global serializer configuration, except for contextual serialization.

If you use the same serializer repeatedly in many places, you can define a `typealias` with an attached serializer annotation.

This lets you reuse the annotated type without adding the `@Serializable` annotation at each usage site.

Here's an example of using `typealias` to apply `DateAsLongSerializer` and `DateAsSimpleTextSerializer` to `Date`:

```kotlin
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*
import java.util.Date
import java.text.SimpleDateFormat
import java.util.TimeZone

object DateAsLongSerializer : KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.DateAsLong",
PrimitiveKind.LONG)
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeLong(value.time)
    override fun deserialize(decoder: Decoder): Date = Date(decoder.decodeLong())
}

// Defines a serializer that encodes Date as a formatted string (yyyy-MM-dd)
object DateAsSimpleTextSerializer: KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.DateAsSimpleText",
PrimitiveKind.LONG)
    private val format = SimpleDateFormat("yyyy-MM-dd").apply {
        // Sets the time zone to UTC for consistent output
        setTimeZone(TimeZone.getTimeZone("UTC"))
    }
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeString(format.format(value))
    override fun deserialize(decoder: Decoder): Date = format.parse(decoder.decodeString())
}

// Applies global serializers using typealias to avoid annotating each occurrence
typealias DateAsLong = @Serializable(DateAsLongSerializer::class) Date

typealias DateAsText = @Serializable(DateAsSimpleTextSerializer::class) Date

// Uses typealiases to apply custom serializers for Date properties
@Serializable
class ProgrammingLanguage(val stableReleaseDate: DateAsText, val lastReleaseTimestamp: DateAsLong)

fun main() {
    val format = SimpleDateFormat("yyyy-MM-ddX")
    val data = ProgrammingLanguage(format.parse("2016-02-15+00"), format.parse("2022-07-07+00"))

    println(Json.encodeToString(data))
    // {"stableReleaseDate":"2016-02-15","lastReleaseTimestamp":1657152000000}
}
```

Implement contextual serialization

By default, serialization strategies are defined at compile time. *Contextual serialization* allows you to adjust the serialization strategy for specific types at runtime, even when they're nested deep within an object tree.

For example, you can use contextual serialization to serialize `java.util.Date` in JSON format either as an ISO 8601 `String` or as a `Long`, depending on the protocol version being used. This approach is supported by the built-in `ContextualSerializer` class.

Contextual serialization selects a custom serializer for a type at runtime from a `SerializersModule`.

To implement contextual serialization:

1. Mark the property in your serializable class with the `@Contextual` annotation.

> The `@Contextual` annotation is a shortcut for the `ContextualSerializer` class. To apply contextual serialization across multiple properties in the same file, use `@UseContextualSerialization` annotation.

2. Create a `SerializersModule` with the `SerializersModule()` builder function. Use the `contextual()` function to register the custom serializer for contextual serialization.

   Without the `SerializersModule`, a `SerializationException` is thrown during the serialization or deserialization of contextually annotated types that don't have a default serializer.

3. Create a `Json` instance and pass the `SerializersModule` to the `serializersModule` property.

Here's an example:

```
import kotlinx.serialization.*
import kotlinx.serialization.encoding.*
import kotlinx.serialization.descriptors.*
import kotlinx.serialization.json.*
import java.util.Date
import java.text.SimpleDateFormat

// Creates a custom serializer for Date
object DateAsLongSerializer : KSerializer<Date> {
    override val descriptor: SerialDescriptor = PrimitiveSerialDescriptor("my.app.Date",
PrimitiveKind.LONG)
    override fun serialize(encoder: Encoder, value: Date) = encoder.encodeLong(value.time)
    override fun deserialize(decoder: Decoder): Date = Date(decoder.decodeLong())
}

@Serializable
class ProgrammingLanguage(
    val name: String,
    // Specifies contextual serialization for Date
    @Contextual
    val stableReleaseDate: Date
)

// Defines a SerializersModule and registers the contextual serializer for Date
private val module = SerializersModule {
    contextual(DateAsLongSerializer)
}

// Creates a Json instance with the custom SerializersModule
val format = Json { serializersModule = module }

fun main() {
    val data = ProgrammingLanguage("Kotlin", SimpleDateFormat("yyyy-MM-ddX").parse("2016-02-15+00"))

   println(format.encodeToString(data))
    // {"name":"Kotlin","stableReleaseDate":1455494400000}
}
```

Serialize generic classes contextually

To serialize generic classes contextually, you can register a function in the `SerializersModule`. This function receives the serializers for the generic type arguments and creates the corresponding serializer at runtime.

You can't use a single serializer instance for generic classes because generic type arguments can vary. For example, the following approach only works for `Box<Int>`, but not for other types like `Box<String>`:

```
val incorrectModule = SerializersModule {
    // This only works for Box<Int>, but not for Box<String> or other types
    contextual(BoxSerializer(Int.serializer()))
}
```

Instead, register a function that creates a serializer for generic types such as `Box<T>` based on the serializers of their type arguments. Here's an example:

```
val correctModule = SerializersModule {
    // args[0] is the serializer for T,
    // for example Int.serializer() or String.serializer()
    contextual(Box::class) { args -> BoxSerializer(args[0]) }
}
```

You can combine multiple `SerializersModule` instances with the `plus` operator, such as modules for generic and non-generic classes. For more information, see Merge multiple `SerializersModule` instances.

What's next

- Discover how to transform JSON structure by modifying the JSON element tree instead of creating a custom serializer.
- Learn about alternative and custom serialization formats to implement format-specific representations for your data.

Kotlin Metadata JVM library

The `kotlin-metadata-jvm` library provides tools to read, modify, and generate metadata from Kotlin classes compiled for the JVM. This metadata, stored in the `@Metadata` annotation within `.class` files, is used by libraries and tools such as `kotlin-reflect` to inspect Kotlin-specific constructs such as properties, functions, and classes at runtime.

The `kotlin-reflect` library relies on metadata to retrieve Kotlin-specific class details at runtime. Any inconsistencies between the metadata and the actual `.class` file may lead to incorrect behavior when using reflection.

You can also use the Kotlin Metadata JVM library to inspect various declaration attributes such as visibility or modality, or to generate and embed metadata into `.class` files.

Add the library to your project

To include the Kotlin Metadata JVM library in your project, add the corresponding dependency configuration based on your build tool.

The Kotlin Metadata JVM library follows the same versioning as the Kotlin compiler and standard library. Ensure that the version you use matches your project's Kotlin version.

Gradle

Add the following dependency to your `build.gradle(.kts)` file:

Kotlin

```
// build.gradle.kts
repositories {
    mavenCentral()
}

dependencies {
    implementation("org.jetbrains.kotlin:kotlin-metadata-jvm:2.4.20")
}
```

Groovy

```
// build.gradle
repositories {
    mavenCentral()
}

dependencies {
    implementation 'org.jetbrains.kotlin:kotlin-metadata-jvm:2.4.20'
}
```

Maven

Add the following dependency to your `pom.xml` file.

```
<project>
    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-metadata-jvm</artifactId>
            <version>2.4.20</version>
        </dependency>
    </dependencies>
    ...
</project>
```

Read and parse metadata

The `kotlin-metadata-jvm` library extracts structured information from compiled Kotlin `.class` files, such as class names, visibility, and signatures. You can use it in projects that need to analyze compiled Kotlin declarations. For example, the Binary Compatibility Validator (BCV) relies on `kotlin-metadata-jvm` to print public API declarations.

You can start exploring Kotlin class metadata by retrieving the `@Metadata` annotation from a compiled class using reflection:

```
fun main() {
    // Specifies the fully qualified name of the class
    val clazz = Class.forName("org.example.SampleClass")

    // Retrieves the @Metadata annotation
    val metadata = clazz.getAnnotation(Metadata::class.java)

    // Checks if the metadata is present
    if (metadata ≠ null) {
        println("This is a Kotlin class with metadata.")
    } else {
        println("This is not a Kotlin class.")
    }
}
```

After retrieving the `@Metadata` annotation, use either the `readLenient()` or the `readStrict()` function from the `KotlinClassMetadata` API to parse it. These functions extract detailed information about classes or files, while addressing different compatibility requirements:

- `readLenient()` : Use this function to read metadata, including metadata generated by newer Kotlin compiler versions. This function doesn't support modifying or writing metadata.
- `readStrict()` : Use this function when you need to modify and write metadata. The `readStrict()` function only works with metadata generated by Kotlin compiler versions fully supported by your project.

> The `readStrict()` function supports metadata formats up to one version beyond `JvmMetadataVersion.LATEST_STABLE_SUPPORTED` , which corresponds to the latest Kotlin version used in the project. For example, if your project depends on `kotlin-metadata-jvm:2.1.0` , `readStrict()` can process metadata up to Kotlin `2.2.x` ; otherwise, it throws an error to prevent mishandling unknown formats.
>
> For more information, see the Kotlin Metadata GitHub repository.

When parsing metadata, the `KotlinClassMetadata` instance provides structured information about class or file-level declarations. For classes, use the `kmClass` property to analyze detailed class-level metadata, such as the class name, functions, properties, and attributes like visibility. For file-level declarations, the metadata is represented by the `kmPackage` property, which includes top-level functions and properties from file facades generated by the Kotlin compiler.

The following code example demonstrates how to use `readLenient()` to parse metadata, analyze class-level details with `kmClass` , and retrieve file-level declarations with `kmPackage` :

```
// Imports the necessary libraries
import kotlin.metadata.jvm.*
import kotlin.metadata.*

fun main() {
    // Specifies the fully qualified class name
    val className = "org.example.SampleClass"

    try {
        // Retrieves the class object for the specified name
        val clazz = Class.forName(className)

        // Retrieves the @Metadata annotation
        val metadataAnnotation = clazz.getAnnotation(Metadata::class.java)
        if (metadataAnnotation ≠= null) {
            println("Kotlin Metadata found for class: $className")

            // Parses metadata using the readLenient() function
            val metadata = KotlinClassMetadata.readLenient(metadataAnnotation)
            when (metadata) {
                is KotlinClassMetadata.Class → {
                    val kmClass = metadata.kmClass
                    println("Class name: ${kmClass.name}")

                    // Iterates over functions and checks visibility
                    kmClass.functions.forEach { function →
                        val visibility = function.visibility
                        println("Function: ${function.name}, Visibility: $visibility")
                    }
                }
                is KotlinClassMetadata.FileFacade → {
                    val kmPackage = metadata.kmPackage

                    // Iterates over functions and checks visibility
                    kmPackage.functions.forEach { function →
                        val visibility = function.visibility
                        println("Function: ${function.name}, Visibility: $visibility")
                    }
                }
                else → {
                    println("Unsupported metadata type: $metadata")
                }
            }
        } else {
            println("No Kotlin Metadata found for class: $className")
        }
    } catch (e: ClassNotFoundException) {
        println("Class not found: $className")
    } catch (e: Exception) {
        println("Error processing metadata: ${e.message}")
        e.printStackTrace()
    }
}
```

Write and read annotations in metadata

Kotlin stores annotations in both bytecode and Kotlin metadata. If you use the `kotlin-metadata-jvm` library to read or write annotations, you work with their metadata representation.

Kotlin stores annotations in Kotlin metadata starting with Kotlin 2.4.0. If you inspect class files compiled with earlier versions, the annotations aren't present in the metadata.

When you change the annotations in metadata, make sure they stay consistent with the annotations stored in bytecode. If they get out of sync, tools that rely on reflection or bytecode analysis may report different results than tools that read Kotlin metadata.

The `kotlin-metadata-jvm` library provides the following APIs for accessing annotations:

- `KmClass.annotations`
- `KmFunction.annotations`
- `KmProperty.annotations`
- `KmConstructor.annotations`
- `KmPropertyAccessorAttributes.annotations`
- `KmValueParameter.annotations`
- `KmFunction.extensionReceiverAnnotations`
- `KmProperty.extensionReceiverAnnotations`
- `KmProperty.backingFieldAnnotations`
- `KmProperty.delegateFieldAnnotations`
- `KmEnumEntry.annotations`

Here's an example of reading annotations from Kotlin metadata:

```
import kotlin.metadata.ExperimentalAnnotationsInMetadata
import kotlin.metadata.jvm.KotlinClassMetadata

annotation class Label(val value: String)

@Label("Message class")
class Message

fun main() {
    val metadata = Message::class.java.getAnnotation(Metadata::class.java)
    val kmClass = (KotlinClassMetadata.readStrict(metadata) as KotlinClassMetadata.Class).kmClass
    println(kmClass.annotations)
    // [@Label(value = StringValue("Message class"))]
}
```

Extract metadata from bytecode

While you can retrieve metadata using reflection, another approach is to extract it from bytecode using a bytecode manipulation framework such as ASM.

You can do this by following these steps:

1. Read the bytecode of a `.class` file using the ASM library's `ClassReader` class. This class processes the compiled file and populates a `ClassNode` object, which represents the class structure.
2. Extract the `@Metadata` from the `ClassNode` object. The example below uses a custom extension function `findAnnotation()` for this.

3. Parse the extracted metadata using the `KotlinClassMetadata.readLenient()` function.
4. Inspect the parsed metadata with the `kmClass` and `kmPackage` properties.

Here's an example:

```
// Imports the necessary libraries
import kotlin.metadata.jvm.*
import kotlin.metadata.*
import org.objectweb.asm.*
import org.objectweb.asm.tree.*
import java.io.File

// Checks if an annotation refers to a specific name
fun AnnotationNode.refersToName(name: String) =
    desc.startsWith('L') && desc.endsWith(';') && desc.regionMatches(1, name, 0, name.length)

// Retrieves annotation values by key
private fun List<Any>.annotationValue(key: String): Any? {
    for (index in (0 until size / 2)) {
        if (this[index * 2] == key) {
            return this[index * 2 + 1]
        }
    }
    return null
}

// Defines a custom extension function to locate an annotation by its name in a ClassNode
fun ClassNode.findAnnotation(annotationName: String, includeInvisible: Boolean = false):
AnnotationNode? {
    val visible = visibleAnnotations?.firstOrNull { it.refersToName(annotationName) }
    if (!includeInvisible) return visible
    return visible ?: invisibleAnnotations?.firstOrNull { it.refersToName(annotationName) }
}

// Operator to simplify retrieving annotation values
operator fun AnnotationNode.get(key: String): Any? = values.annotationValue(key)

// Extracts Kotlin metadata from a class node
fun ClassNode.readMetadataLenient(): KotlinClassMetadata? {
    val metadataAnnotation = findAnnotation("kotlin/Metadata", false) ?: return null
    @Suppress("UNCHECKED_CAST")
    val metadata = Metadata(
        kind = metadataAnnotation["k"] as Int?,
        metadataVersion = (metadataAnnotation["mv"] as List<Int>?)?.toIntArray(),
        data1 = (metadataAnnotation["d1"] as List<String>?)?.toTypedArray(),
        data2 = (metadataAnnotation["d2"] as List<String>?)?.toTypedArray(),
        extraString = metadataAnnotation["xs"] as String?,
        packageName = metadataAnnotation["pn"] as String?,
        extraInt = metadataAnnotation["xi"] as Int?
    )
    return KotlinClassMetadata.readLenient(metadata)
}

// Converts a file to a ClassNode for bytecode inspection
fun File.toClassNode(): ClassNode {
    val node = ClassNode()
    this.inputStream().use { ClassReader(it).accept(node, ClassReader.SKIP_CODE) }
    return node
}

fun main() {
    val classFilePath = "build/classes/kotlin/main/org/example/SampleClass.class"
    val classFile = File(classFilePath)

    // Reads the bytecode and processes it into a ClassNode object
    val classNode = classFile.toClassNode()

    // Locates the @Metadata annotation and reads it leniently
```

```
    val metadata = classNode.readMetadataLenient()
    if (metadata ≠= null && metadata is KotlinClassMetadata.Class) {
        // Inspects the parsed metadata
        val kmClass = metadata.kmClass

        // Prints class details
        println("Class name: ${kmClass.name}")
        println("Functions:")
        kmClass.functions.forEach { function →
            println("- ${function.name}, Visibility: ${function.visibility}")
        }
    }
}
```

Modify metadata

When using tools like ProGuard to shrink and optimize bytecode, some declarations may be removed from `.class` files. ProGuard automatically updates metadata to keep it consistent with the modified bytecode.

However, if you're developing a custom tool that modifies Kotlin bytecode in a similar way, you need to ensure that metadata is adjusted accordingly. With the `kotlin-metadata-jvm` library, you can update declarations, adjust attributes, and remove specific elements.

For example, if you use a JVM tool that deletes private methods from Java class files, you must also delete private functions from Kotlin metadata to maintain consistency:

1. Parse the metadata by using the `readStrict()` function to load the `@Metadata` annotation into a structured `KotlinClassMetadata` object.
2. Apply modifications by adjusting the metadata, such as filtering functions or altering attributes, directly within `kmClass` or other metadata structures.
3. Use the `write()` function to encode the modified metadata into a new `@Metadata` annotation.

Here's an example where private functions are removed from a class's metadata:

```
// Imports the necessary libraries
import kotlin.metadata.jvm.*
import kotlin.metadata.*

fun main() {
    // Specifies the fully qualified class name
    val className = "org.example.SampleClass"

    try {
        // Retrieves the class object for the specified name
        val clazz = Class.forName(className)

        // Retrieves the @Metadata annotation
        val metadataAnnotation = clazz.getAnnotation(Metadata::class.java)
        if (metadataAnnotation ≠ null) {
            println("Kotlin Metadata found for class: $className")

            // Parses metadata using the readStrict() function
            val metadata = KotlinClassMetadata.readStrict(metadataAnnotation)
            if (metadata is KotlinClassMetadata.Class) {
                val kmClass = metadata.kmClass

                // Removes private functions from the class metadata
                kmClass.functions.removeIf { it.visibility == Visibility.PRIVATE }
                println("Removed private functions. Remaining functions: ${kmClass.functions.map {
it.name }}")

                // Serializes the modified metadata back
                val newMetadata = metadata.write()
                // After modifying the metadata, you need to write it into the class file
                // To do so, you can use a bytecode manipulation framework such as ASM

                println("Modified metadata: ${newMetadata}")
            } else {
                println("The metadata is not a class.")
            }
        } else {
            println("No Kotlin Metadata found for class: $className")
        }
    } catch (e: ClassNotFoundException) {
        println("Class not found: $className")
    } catch (e: Exception) {
        println("Error processing metadata: ${e.message}")
        e.printStackTrace()
    }
}
```

Instead of separately calling `readStrict()` and `write()`, you can use the `transform()` function. This function parses metadata, applies transformations through a lambda, and writes the modified metadata automatically.

Create metadata from scratch

To create metadata for a Kotlin class file from scratch using the Kotlin Metadata JVM library:

1. Create an instance of `KmClass`, `KmPackage`, or `KmLambda`, depending on the type of metadata you want to generate.
2. Add attributes to the instance, such as the class name, visibility, constructors, and function signatures.

> You can use the `apply()` scope function to reduce boilerplate code while setting properties.

3. Use the instance to create a `KotlinClassMetadata` object, which can generate a `@Metadata` annotation.
4. Specify the metadata version, such as `JvmMetadataVersion.LATEST_STABLE_SUPPORTED`, and set flags (`0` for no flags, or copy flags from existing files if necessary).
5. Use the `ClassWriter` class from ASM to embed metadata fields, such as `kind`, `data1` and `data2` into a `.class` file.

The following example demonstrates how to create metadata for a simple Kotlin class:

```
// Imports the necessary libraries
import kotlin.metadata.*
import kotlin.metadata.jvm.*
import org.objectweb.asm.*

fun main() {
    // Creates a KmClass instance
    val klass = KmClass().apply {
        name = "Hello"
        visibility = Visibility.PUBLIC
        constructors += KmConstructor().apply {
            visibility = Visibility.PUBLIC
            signature = JvmMethodSignature("<init>", "()V")
        }
        functions += KmFunction("hello").apply {
            visibility = Visibility.PUBLIC
            returnType = KmType().apply {
                classifier = KmClassifier.Class("kotlin/String")
            }
            signature = JvmMethodSignature("hello", "()Ljava/lang/String;")
        }
    }

    // Serializes a KotlinClassMetadata.Class instance, including the version and flags, into a
@kotlin.Metadata annotation
    val annotationData = KotlinClassMetadata.Class(
        klass, JvmMetadataVersion.LATEST_STABLE_SUPPORTED, 0
    ).write()

    // Generates a .class file with ASM
    val classBytes = ClassWriter(0).apply {
        visit(Opcodes.V1_6, Opcodes.ACC_PUBLIC, "Hello", null, "java/lang/Object", null)
        // Writes @kotlin.Metadata instance to the .class file
        visitAnnotation("Lkotlin/Metadata;", true).apply {
            visit("mv", annotationData.metadataVersion)
            visit("k", annotationData.kind)
            visitArray("d1").apply {
                annotationData.data1.forEach { visit(null, it) }
                visitEnd()
            }
            visitArray("d2").apply {
                annotationData.data2.forEach { visit(null, it) }
                visitEnd()
            }
            visitEnd()
        }
        visitEnd()
    }.toByteArray()

    // Writes the generated .class file to disk
    java.io.File("Hello.class").writeBytes(classBytes)

    println("Metadata and .class file created successfully.")
}
```

Overview

Lincheck is a framework for testing concurrent code on the JVM. When running tests, Lincheck explores the potential thread interleavings of the program and reports the ones that lead to incorrect behavior.

> In Kotlin Multiplatform projects, you can use Lincheck to test code only on the JVM.

A concurrency test in Lincheck only requires you to list the operations for each thread and the expected assertions. Lincheck handles the rest:

```
class CounterTest {
    @Test // Test function declaration
    fun test() = Lincheck.runConcurrentTest {
        var counter = 0

        // Increments the counter concurrently
        val t1 = thread { counter++ }
        val t2 = thread { counter++ }

        // Waits for the threads to finish
        t1.join()
        t2.join()

        // Checks that both increments have been applied
        assertEquals(2, counter)
    }
}
```

If the test fails, Lincheck provides the thread interleaving and the thread switch points that led to an error:

```
| ------------------------------------------------------------------------- |
|                  Main Thread                   |   Thread 1    |   Thread 2    |
| ------------------------------------------------------------------------- |
| thread(block = Lambda#2): Thread#1             |               |               |
| thread(block = Lambda#3): Thread#2             |               |               |
| switch (reason: waiting for Thread 1 to finish) |               |               |
|                                                |               | run()         |
|                                                |               |   counter → 0 |
|                                                |               |   switch      |
|                                                | run()         |               |
|                                                |   counter → 0 |               |
|                                                |   counter = 1 |               |
|                                                |               |   counter = 1 |
| Thread#1.join()                                |               |               |
| Thread#2.join()                                |               |               |
| counter.element → 1                            |               |               |
| assertEquals(2, 1): threw AssertionFailedError |               |               |
| ------------------------------------------------------------------------- |
```

How Lincheck works

Each time the JVM runs concurrent code, the execution order of the operations across threads might change. For example, an operation can be interrupted by another operation in a different thread. This is not an error by itself, but can lead to an error if the code has concurrency bugs.

The image compares the execution scenario of a program to execution schedules. In the first execution schedule, operations are performed one after the other. In the second execution schedule, the first operation is interrupted by the second operation.

> An *execution scenario* defines how operations are distributed across the threads and the order of execution within each thread.
>
> An *execution schedule* (also called *thread interleaving*) defines the order of execution for all operations across all threads.

Lincheck implements two testing strategies to find execution schedules that lead to incorrect behavior:

- **Model checking**. Lincheck controls scheduling by inserting explicit thread switch instructions into the program. These instructions are placed at synchronization points or shared memory accesses. Model checking enables Lincheck to generate an exact execution trace that leads to an error.
- **Stress testing**. The operating system controls scheduling. Lincheck executes each scenario multiple times to increase the chances of finding an error.

Getting started with Lincheck

This quickstart will guide you through setting up Lincheck, writing your first Lincheck tests, and interpreting the test reports.

You will:

- Create a new IntelliJ IDEA project and install Lincheck.
- Write your first concurrent test and run it with Lincheck.
- Create a concurrent data structure and test it with Lincheck using two testing strategies.

Create a project

Open an existing Kotlin project in IntelliJ IDEA or create a new one.

Add dependencies

To use Lincheck in the project, add the corresponding dependencies to your build configuration:

Kotlin

```
// build.gradle.kts
repositories {
    mavenCentral()
}

dependencies {
    testImplementation("org.jetbrains.lincheck:lincheck:3.7")
    testImplementation(kotlin("test"))
}
```

Groovy

```
// build.gradle
repositories {
    mavenCentral()
}

dependencies {
    testImplementation "org.jetbrains.lincheck:lincheck:3.7"
    testImplementation "org.jetbrains.kotlin:kotlin-test"
}
```

Maven

```
<!-- pom.xml -->
<project>
    <dependencies>
        <dependency>
            <groupId>org.jetbrains.lincheck</groupId>
            <artifactId>lincheck</artifactId>
            <version>3.7</version>
            <scope>test</scope>
        </dependency>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-test</artifactId>
            <scope>test</scope>
        </dependency>
    </dependencies>
    ...
</project>
```

Write your first test

For a basic concurrent test, create a test function that describes what operations should be executed in each thread and the expected assertions. Lincheck explores possible thread interleavings of the program using model checking and provides an error report in case of incorrect behavior.

1. In the `src/test` directory, create a `CounterTest.kt` file.
2. Import the `org.jetbrains.lincheck`, `kotlinx.concurrent`, and `kotlin.test` libraries:

```
import org.jetbrains.lincheck.Lincheck
import kotlin.test.*
import kotlin.concurrent.thread
```

3. Write a test that creates a variable and two threads manipulating that variable:

```
class CounterTest {
    @Test // Test function declaration
    fun test() = Lincheck.runConcurrentTest {
        var counter = 0

        // Increments the counter concurrently
        val t1 = thread { counter++ }
        val t2 = thread { counter++ }

        // Waits for the threads to finish
        t1.join()
        t2.join()

        // Checks that both increments have been applied
        assertEquals(2, counter)
    }
}
```

4. Run the test. Lincheck generates a report with a thread interleaving that led to incorrect behavior:

Install the Lincheck plugin to visualize the error trace.

```
| ------------------------------------------------------------------------ |
|                  Main Thread                   |   Thread 1    |   Thread 2    |
| ------------------------------------------------------------------------ |
| thread(block = Lambda#2): Thread#1             |               |               |
| thread(block = Lambda#3): Thread#2             |               |               |
| switch (reason: waiting for Thread 1 to finish) |               |               |
|                                                |               | run()         |
|                                                |               |   counter → 0 |
|                                                |               |   switch      |
|                                                | run()         |               |
|                                                |   counter → 0 |               |
|                                                |   counter = 1 |               |
|                                                |               |   counter = 1 |
| Thread#1.join()                                |               |               |
| Thread#2.join()                                |               |               |
| counter.element → 1                            |               |               |
| assertEquals(2, 1): threw AssertionFailedError  |               |               |
| ------------------------------------------------------------------------ |
```

Lincheck found a thread interleaving where one of the `inc()` operations overwrites the `counter` value.

Step-by-step report explanation

1. In Thread 2, the JVM reads the initial `counter` value.
2. The execution switches from Thread 2 to Thread 1.
3. In Thread 1, the JVM increments the counter. All steps of the `inc()` operation are performed without interruptions: reading the value from the variable, incrementing the value, and writing the value back to the variable.
4. The execution switches back to Thread 2.
5. In Thread 2, the JVM increments the value acquired at step 1 and writes the result to the `counter` variable.

Write a test for a data structure

In addition to basic concurrent tests, Lincheck supports a declarative approach to testing concurrent data structures.

To test a data structure in Lincheck, you only need to declare the concurrent methods of the structure and a test function. Lincheck generates random concurrent scenarios, executes them using the specified testing strategy, and provides error reports.

In this section, you will test a simple counter:

1. In the `src/test` directory, create a `CounterStructureTest.kt` file.
2. Import the `lincheck.datastructures` and `kotlin.test` libraries:

```
import org.jetbrains.lincheck.datastructures.*
import kotlin.test.*
```

3. Create a `Counter` structure:

```
class Counter {
    var value = 0

    fun inc(): Int = ++value
    fun dec(): Int = --value
}
```

4. Create a `CounterStructureTest` class. Set the initial state of the structure and mark the concurrent operations of the structure with the `@Operation` annotation:

```
class CounterStructureTest {
    private val c = Counter()

    @Operation
    fun inc() = c.inc()

    @Operation
    fun dec() = c.dec()
        .iterations(100) // Specify the number of generated scenarios
```

5. In the `CounterStructureTest` class, declare a test function using `ModelCheckingOptions()`:

```
@Test
    fun test() = ModelCheckingOptions().check(this::class)
```

> Learn how model checking works in the Testing Strategies article.

6. Run the test. Lincheck generates an error report with the concurrent scenario and the specific thread interleaving that led to incorrect behavior:

```
| ------------------- |
| Thread 1 | Thread 2 |
| ------------------- |
| inc(): 1 | inc(): 1 |
| ------------------- |
```

```
| ------------------------ |
| Thread 1 |   Thread 2    |
| ------------------------ |
|          | inc(): 1      |
|          |   c.inc(): 1  |
|          |     value → 0 |
|          |     switch    |
| inc(): 1 |               |
|          |     value = 1 |
|          |     value → 1 |
|          |   result: 1   |
| ------------------------ |
```

What's next

Learn about the declarative approach to testing concurrent data structures in Lincheck.

Testing arbitrary code

Lincheck provides a `runConcurrentTest()` function to test arbitrary concurrent code.

The `runConcurrentTest()` function executes a block of concurrent code multiple times and uses model checking to explore its potential execution schedules.

To test concurrent code with Lincheck:

1. Create a test class:

```
class CounterTestWithInvocations {
}
```

2. Create a test function as a member function using `runConcurrentTest()`:

```
@Test
    fun test() = Lincheck.runConcurrentTest(100_000) {
        var counter = 0

        // Increments the counter concurrently
        val t1 = thread { counter++ }
        val t2 = thread { counter++ }

        // Waits for the threads to finish
        t1.join()
        t2.join()

        // Checks that both increments have been applied
        assertEquals(2, counter)
    }
```

> The function parameter is optional; it specifies the number of execution schedules to explore. The default value is `10_000`.

3. Run the test. If it fails, Lincheck generates a report with an execution schedule that leads to incorrect behavior.

```
| ------------------------------------------------------------------------ |
|                  Main Thread                   |   Thread 1    |   Thread 2    |
| ------------------------------------------------------------------------ |
| thread(block = Lambda#2): Thread#1             |               |               |
| thread(block = Lambda#3): Thread#2             |               |               |
| switch (reason: waiting for Thread 1 to finish) |               |               |
|                                                |               | run()         |
|                                                |               |   counter → 0 |
|                                                |               |   switch      |
|                                                | run()         |               |
|                                                |   counter → 0 |               |
|                                                |   counter = 1 |               |
|                                                |               |   counter = 1 |
| Thread#1.join()                                |               |               |
| Thread#2.join()                                |               |               |
| counter.element → 1                            |               |               |
| assertEquals(2, 1): threw AssertionFailedError |               |               |
| ------------------------------------------------------------------------ |
```

Example: test `ConcurrentHashMap` functions

Consider this test for `ConcurrentHashMap` functions:

```
package org.lincheck.docs

import org.jetbrains.lincheck.*
import kotlin.test.Test
import java.util.concurrent.*
import kotlin.concurrent.*

// This test demonstrates a deadlock caused by two threads
// performing nested `computeIfAbsent` calls in opposite order.
class ConcurrentHashMapDeadlockTest {
    @Test
    fun test() = Lincheck.runConcurrentTest {
        val map = ConcurrentHashMap<String, String>()

        // Updates `key2` while locking `key1`.
        val thread1 = thread {
            map.computeIfAbsent("key1") {
                map.computeIfAbsent("key2") { "value2" }
                "value1"
            }
        }

        // Updates `key1` while locking `key2`.
        val thread2 = thread {
            map.computeIfAbsent("key2") {
                map.computeIfAbsent("key1") { "value1" }
                "value2"
            }
        }

        // Wait until both threads complete.
        thread1.join()
        thread2.join()
    }
}
```

The test fails due to Lincheck finding an execution schedule that leads to a deadlock:

1. Thread 2 maps `key2` to the bucket at index 1, places a lock on this bucket, and starts executing `computeIfAbsent("key1")`. The execution switches from Thread 2 to Thread 1 **before** Thread 2 maps `key1` and locks the bucket with `key1`.
2. Thread 1 maps `key1` to the bucket at index 0, places a lock on this bucket, and starts executing `computeIfAbsent("key2")`. Thread 1 maps `key2` to the bucket at index 1 and tries to lock the bucket, but it is already locked by Thread 2. The execution switches from Thread 1 to Thread 2.
3. Thread 2 tries to lock the bucket with `key1`, but it is already locked by Thread 1.

Both threads are locked, so the execution has encountered a deadlock.

A screenshot of the Lincheck report for the failed test.

How to test data structures

Lincheck provides a declarative interface for testing concurrent data structures. Instead of describing how to perform the test, you declare all the operations that need to be tested, and Lincheck generates concurrent execution scenarios, runs them, and analyzes the results.

Let's test this `Counter` data structure with Lincheck:

```
class Counter {
    var value = 0

    fun inc(): Int = ++value
    fun dec(): Int = --value
}
```

1. Create a test class:

   ```
   class CounterTest {
   }
   ```

2. Create a class property that holds an instance of your structure:

   ```
   private val c = Counter()
   ```

3. Declare the operations you want to test as member functions and annotate them with `@Operation`:

```
@Operation
    fun inc() = c.inc()

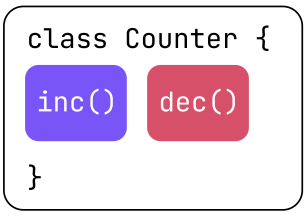
    @Operation
    fun dec() = c.dec()
```

This annotation tells Lincheck which methods to include when generating execution scenarios.

4. Declare a test function as a member function using `ModelCheckingOptions()` or `StressOptions()`. Annotate it with `@Test`:

```
@Test
    fun test() = ModelCheckingOptions().check(this::class)
```

> Learn about the differences between model checking and stress testing in the Testing Strategies article.

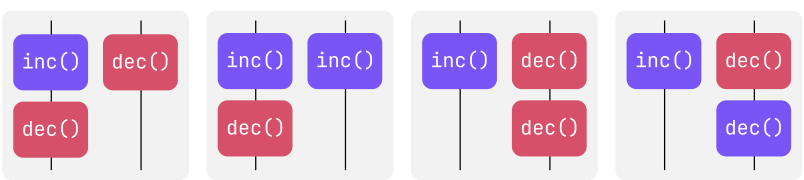


5. Run the test. If it fails, Lincheck generates an error report with the scenario and execution trace that led to incorrect behavior:

```
= Invalid execution results =
| ------------------- |
| Thread 1  | Thread 2 |
| ------------------- |
| dec(): -1 | inc(): 1 |
| ------------------- |
```

The testing process

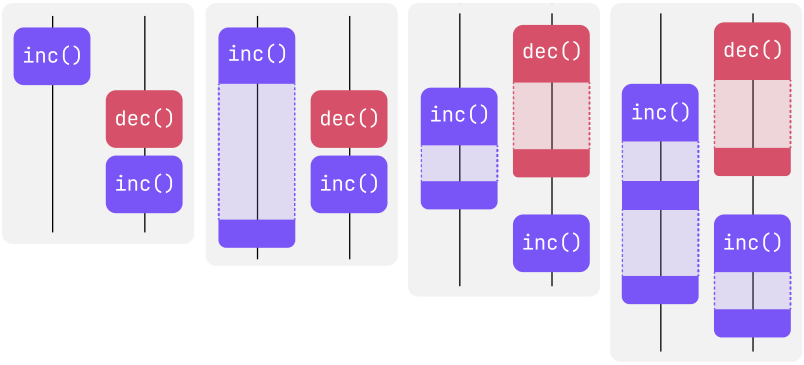
When testing a data structure, Lincheck generates a list of execution scenarios, runs them, and analyzes the results.



Consider this `Counter` data structure:

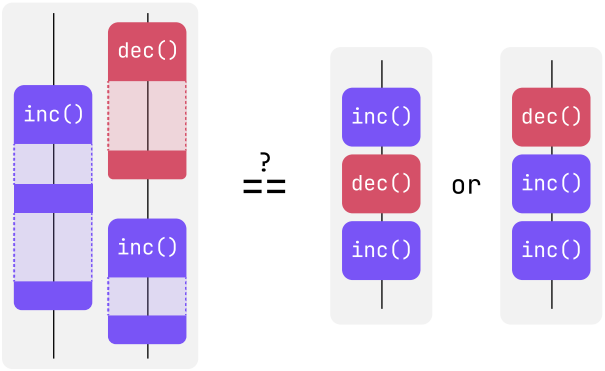
A diagram of a Counter data structure with two methods: inc() and dec()

To test it, Lincheck performs the following steps:



1. Generates a list of random execution scenarios by randomly placing declared operations across different threads:

A diagram of four execution scenarios. In each scenario, operations are placed in different orders in two threads.



You can specify the number of threads and the number of operations per thread using the configuration options provided by Lincheck.

2. Executes the generated scenarios using the specified testing strategy: model checking or stress testing. Each of the generated scenarios is executed multiple times to examine different execution schedules:

A diagram of four execution schedules. All schedules correspond to a single execution scenario. In each schedule, the operations interrupt each other at different times.

3. Verifies the results of the execution against the correctness property. By default, it's linearizability.

A diagram of the verification process. The results of one execution schedule are compared to the results of the same operations executed sequentially.

At this step, Lincheck can also validate the structure if provided with a validation function.

Example: test an implementation of a Treiber stack structure

Consider this *incorrect* implementation of a Treiber Stack:

```
class TreiberStack<E> {
    private val top = AtomicReference<Node<E>?>(null)

    fun push(item: E) {
        val newHead = Node(item)
        var oldHead: Node<E>?

        do {
            oldHead = top.get()
            newHead.next = oldHead
        } while (!top.compareAndSet(oldHead, newHead))
    }

    fun pop(): E? {
        val oldHead = top.get()

        if (oldHead == null) {
            return null
        }

        val newHead = oldHead.next
        top.compareAndSet(oldHead, newHead)

        // Bug: by the time `pop()` finishes execution,
        // another thread might have already popped this item.
        return oldHead.item
    }

    private class Node<E>(
        val item: E,
        var next: Node<E>? = null
    )
}
```

You can test this structure with Lincheck to examine how the injected bug affects the behavior of the program:

1. Create a test structure:

```
class TreiberStackTest {
    private val stack = TreiberStack<Int>()

    @Operation
    fun push(value: Int) = stack.push(value)

    @Operation
    fun pop(): Int? = stack.pop()

    @Test
    fun modelCheckingTest() = ModelCheckingOptions()
        .check(this::class)
}
```

2. Run the test. Lincheck generates an error report and provides the execution scenario that causes incorrect behavior:

```
| ------------------------------ |
|   Thread 1    |    Thread 2    |
| ------------------------------ |
| push(1): void |                |
| ------------------------------ |
| pop(): 1      | push(-1): void |
| ------------------------------ |
| pop(): -1     |                |
| pop(): 1      |                |
| ------------------------------ |
```

This diagram shows how the operations are placed across different threads and the return values of the operations. Lincheck also provides the specific thread interleaving that leads to incorrect results:

```
| ------------------------------------------------------ |
|                  Thread 1                  | Thread 2  |
| ------------------------------------------------------ |
| push(1)                                    |           |
| ------------------------------------------------------ |
| pop(): 1                                   |           |
|   stack.pop(): 1                           |           |
|     top.get(): Node#1                      |           |
|     switch                                 |           |
|                                            | push(-1)  |
|     oldHead.getNext(): null                |           |
|     top.compareAndSet(Node#1, null): false |           |
|     oldHead.getItem(): 1                   |           |
|   result: 1                                |           |
| ------------------------------------------------------ |
| pop(): -1                                  |           |
| pop(): 1                                   |           |
| ------------------------------------------------------ |
```

Because the implementation does not account for another thread interrupting the `pop()` function, `pop()` returns `1` twice, which should not be possible.

3. Fix the data structure. A correct implementation updates the `oldHead` variable to the most recent value before returning the results:

```
fun pop(): E? {
        var oldHead: Node<E>?
        var newHead: Node<E>?

        do {
            oldHead = top.get()
            if (oldHead == null) return null
            newHead = oldHead.next
        } while (!top.compareAndSet(oldHead, newHead))

        return oldHead.item
    }
```

Testing strategies

Lincheck provides two strategies for testing concurrent data structures: model checking and stress testing.

In this article, you will learn the difference between the strategies and what to keep in mind when choosing a testing strategy.

Model checking

With model checking, Lincheck simulates possible thread interleavings and reports those that cause incorrect behavior.

To use model checking for testing a data structure, declare a test function using `ModelCheckingOptions()`:

```
@Test
    fun test() = ModelCheckingOptions().check(this::class)
```

When using the model checking strategy, Lincheck inserts explicit thread-switch instructions at points of shared-memory access (`read` and `write`) or at synchronization points, such as lock acquisition and release, `park`/`unpark`, `wait`/`notify`, and others.

Controlling the thread switching enables Lincheck to:

- Deterministically explore different possible execution schedules of a program.
- Provide detailed execution traces.

Currently, model checking requires Lincheck to assume a sequentially consistent memory model of the execution. This means that Lincheck does not simulate and cannot catch bugs related to instruction reordering, memory cache behavior, and other similar effects under the relaxed Java memory model.

> For more information, see Model checking.

Stress testing

With stress testing, Lincheck executes each scenario multiple times to increase the chances of finding an error.

To use stress testing, declare a test function using `StressOptions()`:

```
@Test
    fun stressTest() = StressOptions().check(this::class)
```

Unlike with model checking, Lincheck does not control or track thread switches. This makes stress testing faster and does not require Lincheck to make any assumptions about the memory model. However, with stress testing, tests are not reproducible, and Lincheck cannot provide an execution trace.

Choose a strategy

When choosing a strategy, consider the following:

	Model checking	Stress testing
Speed	Slower.	Faster.
Reproducibility	The tests return exactly the same results if the input data has not changed.	The tests might return different results as the thread schedules might change from run to run.
Assumptions	• Assumes a sequentially consistent memory model. • Will miss bugs caused by incorrect behavior outside of that model.	• Does not make any assumptions about a memory model. • Has a chance to catch any incorrect behavior regardless of the underlying cause.
Verbosity	Reports both a concurrent scenario and an execution trace that led to incorrect behavior.	Reports only a concurrent scenario.
Standard library coverage	• Does not simulate the behavior of some standard library features, such as weak references. • Will miss bugs caused by such features.	Has a chance to catch a bug caused by the usage of any feature.

What's next

Learn how to configure a testing strategy by customizing scenario generation, enabling stalled execution detection, and providing thread-safety guarantees for libraries.

Configuring a testing strategy

Lincheck supports various configuration options for testing strategies, including scenario generation, detection of stalled execution, verification, and others.

How to enable options

To enable an option for a testing strategy, set it in the strategy class:

```
@Test
    fun testWithIterations() = ModelCheckingOptions()
        .iterations(100) // Specify the number of generated scenarios
        .check(this::class)
```

Scenario minimization

By default, Lincheck tries to minimize the failed scenario by removing the operations that do not change the behavior of the test.

Set the `minimizeFailedScenario` option to `false` to see the full failed scenario.

```
| ------------------------- |
|    Thread 1    | Thread 2 |
| -------------------------|
| inc(): 1       |          |
| get(): 1       |          |
| get(): 1       |          |
| -------------------------|
| inc(): 4 [0,1] | inc(): 2 |
| get(): 4 [1,1] | inc(): 4 |
| get(): 4 [2,1] | get(): 4 |
| -------------------------|
| get(): 4       |          |
| get(): 4       |          |
| get(): 4       |          |
| -------------------------|
```

```
| ------------------ |
| Thread 1 | Thread 2 |
| ------------------ |
| inc(): 1 | inc(): 1 |
| ------------------ |
```

Scenario generation

Option	Default value	Description
`iterations`	`100`	The number of generated concurrent scenarios.

Option	Default value	Description
`invocationsPerIteration`	`10_000`	The number of invocations for each concurrent scenario.
`threads`	`2`	The number of threads in each scenario.
`actorsBefore`	`5`	The number of operations called before the parallel section of a scenario.
`actorsPerThread`	`5`	The number of operations in each thread in the parallel section of a scenario.
`actorsAfter`	`5`	The number of operations called after the parallel section of a scenario.
`customScenarios`	–	A list of custom concurrent scenarios. The custom scenarios are executed before the randomly generated ones.

Defining a custom scenario

Lincheck uses a domain-specific language for defining custom scenarios:

```
@Test
    fun test() = StressOptions()
        .addCustomScenario {
            initial {
                actor(Structure::noArgsOp)
            }
            parallel {
                thread {
                    actor(Structure::argsOp, 1)
                    actor(Structure::argsOp, 2)
                }
                thread {
                    actor(Structure::argsOp, 3)
                }
            }
            post {
                actor(Structure::noArgsOp)
            }
        }
        // Report the scenarios even if the test has not failed
        // The custom scenario should be first in the list of scenarios
        .logLevel(LoggingLevel.INFO)
        .check(this::class)
```

Each scenario consists of three optional sections:

- `initial` – operations executed before the parallel part.
- `parallel` – thread definitions. Threads are defined using the `thread` block. The parallel section might contain multiple `thread` blocks.
- `post` – operations executed after the parallel part.

Operations are defined using the `actor(function, arg1, arg2, ...)` function. Operations within a single block are executed sequentially.

Stalled execution detection

Option	Default value	Description
`timeoutMs`	`3000`	Invocation timeout in milliseconds after which Lincheck reports a stalled execution.
`loopBound`	`50`	The number of loop iterations after which Lincheck reports a stalled execution. Increase the value of `loopBound` if Lincheck falsely reports stalled execution for long loops. This option can only be applied to model checking.
`recursionBound`	`20`	The number of recursive calls after which Lincheck reports a stalled execution. The value of `loopIterationsBeforeThreadSwitch` should be less than `loopBound`. This option can only be applied to model checking.

Thread switching in loops

Option	Default value	Description
`loopIterationsBeforeThreadSwitch`	`10`	The number of loop iterations a thread can perform before trying to switch to another thread. The value of `loopIterationsBeforeThreadSwitch` should be less than `loopBound`. This option can only be applied to model checking.

Verification

Option	Default value	Description
`verifierClass`	`LinearizabilityVerifier`	The verifier class used during the verification process: • `LinearizabilityVerifier` • `SerializabilityVerifier` • `QuiescentConsistencyVerifier`
`sequentialSpecification`	Same as the tested data structure.	The sequential version of the tested data structure. This structure is used during the verification process.

Progress guarantees

Option	Default value	Description
`checkObstructionFreedom`	`false`	Set this option to `true` to verify the obstruction-freedom guarantee of the data structure operations. This option can only be applied to model checking.

Library analysis

Option	Default value	Description
`stdLibAnalysisEnabled`	`false`	By default, Lincheck does not verify the behavior of the operations from the standard library, treating them as thread-safe. Set this option to `true` to enable analysis of standard library functions/classes. This option can only be applied to model checking.
`addGuarantee`	–	Define guarantees for thread-safe or irrelevant to analysis methods using the `addGuarantee` option to exclude them from model checking. This option can only be applied to model checking.

Defining a guarantee

To define a guarantee, use a builder chain: select classes, then methods, then the guarantee type.

```
@Test
    fun modelCheckingWithGuaranteesTest() = ModelCheckingOptions()
        .addGuarantee(
            forClasses("java.util.concurrent.ConcurrentHashMap")
                .allMethods()
                .treatAsAtomic()
        )
        .check(this::class)
```

1. Select classes using one of the `forClasses` overloads:
   - `forClasses(vararg fullClassNames: String)` — matches classes if their full name is present in the `fullClassNames` string.
   - `forClasses(vararg classes: KClass<*>)` — matches classes by reference.
   - `forClasses(classPredicate: (fullClassName: String) -> Boolean)` — match classes using a predicate on full class names.
2. Select methods to apply the guarantee to:
   - `methods(methodNames: String)` – matches methods if their name is present in the `methodNames` string.
   - `methods(methodPredicate: (methodName: String) -> Boolean)` – matches methods using a predicate.
   - `allMethods()` – match all methods of the selected classes.
3. Choose the guarantee type:
   - `treatAsAtomic()` — treat each method as an atomic operation. Lincheck will not insert switch points inside the method call, but might add them before or after the call.

     Use `treatAsAtomic()` for methods that are known to be thread-safe.
   - `ignore()` — exclude the methods from analysis. Lincheck will not insert switch points inside, before, or after the method calls.

     > If a method uses synchronization primitives internally (for instance, `synchronized` blocks), ignoring the method may cause Lincheck to deadlock.

     Use `ignore()` for methods that are irrelevant to analysis, such as logging or debugging utilities.

What's next

Learn how to configure argument generation for operations used in Lincheck's execution scenarios.

See also

- Configuring operation execution options
- Checking for non-blocking progress guarantees
- Defining a sequential specification of an algorithm

Argument generation constraints

To test a concurrent data structure, Lincheck generates a set of concurrent scenarios by placing the operations randomly in different threads and invoking them with random arguments.

You can constrain the range of operation arguments to increase the chance of finding a concurrency bug. For example, concurrent operations in a hash map are more likely to access the same key if the range of possible key values is limited. This enables Lincheck to expose race conditions and other concurrency bugs more efficiently.

To limit the range of the generated argument values in Lincheck:

1. Use the `@Param` annotation to declare an argument generator:

```
@Param(name = "key", gen = IntGen::class, conf = "1:2")
class MultiMapTest {
}
```

   - `name` – the name of the argument generator.
   - `gen` – the type of the generator.
   - `conf` – the configuration string for the generator. Here, Lincheck generates integer values from 1 to 2.

   > Lincheck provides generators for multiple value types. Each type uses a different configuration string template.
   >
   > Read more in the Generator types section.

2. Annotate the operations parameters with `@Param` to apply the constraints:

```
@Operation
    fun add(@Param(name = "key") key: Int, value: Int) = map.add(key, value)

    @Operation
    fun get(@Param(name = "key") key: Int) = map.get(key)
```

With the constraints in place, Lincheck generates scenarios using only values within the specified range:

```
| ---------------------------------- |
|    Thread 1     |     Thread 2     |
| ---------------------------------- |
| add(2, 0): void | add(2, -1): void |
| ---------------------------------- |
| get(2): [-1]    |                  |
| ---------------------------------- |
```

Generator types

Lincheck provides the following argument generator types:

Generator	Configuration template	Description
		If the configuration string is empty, uses the full integer range from `Int.MIN_VALUE` to `Int.MAX_VALUE`. Example: `"1:3" -> [1, 2, 3]`

`StringGen`	`"maxWordLength:alphabet"`
	`"maxWordLength"`
	`""`
		Generates random string values up to `maxWordLength` from the provided `alphabet`. The default `alphabet` is `[a-zA-Z\d _]`.
		The default `maxWordLength` is `15`.
		
		Example:
		
		`"2:abc" → [ "a", "b", "c", "aa", "bb", "cc", "ab", "bc", "ac", "ba", "cb", "ca" ]`

`EnumGen`	`"Enum.Const1,Enum.Const2,..."`	Generates a random value from the specified list of enum values. Example: `"Enum.Const1,Enum.Const2" → [ Enum.Const1, Enum.Const2 ]`
`BooleanGen`	`""`	Generates `true` and `false` values. Does not require a specific configuration string. Example: `"" -> [true, false]`

`DoubleGen`	`"start:step:end"`
	`"start:end"`
	`""`
		Generates `Double` values from `start` to `end`, incrementing by `step`.
		
		Default `step` value is `(end - start)/100`.
		
		If the configuration string is empty, generates values from `Int.MIN_VALUE` to `Int.MAX_VALUE` with `step = 0.1`.
		
		Example: `"0.0:0.1:1.0" -> [0.0, 0.1, 0.2, ..., 0.9, 1.0]`

`FloatGen`	`"start:step:end"`
	`"start:end"`
	`""`
		Same as `DoubleGen` with values converted to `Float`.
		
		Example: `"0.0:0.1:1.0" -> [0.0, 0.1, 0.2, ..., 0.9, 1.0]`

Generator	Configuration template	Description
`LongGen`	`"min:max"`	Same as `IntGen` with values converted to `Long`. Example: `"1:3" -> [1, 2, 3]`
`ShortGen`	`"min:max"`	Generates `Short` values between `min` and `max`, inclusive. If the configuration string is empty, uses the full short integer range from `-32768` to `32767`. Example: `"1:3" -> [1, 2, 3]`
`ByteGen`	`"min:max"`	Generates `Byte` values between `min` and `max`, inclusive. If the configuration string is empty, uses the full byte range from `-128` to `127`. Example: `"1:3" -> [1, 2, 3]`
`ThreadIdGen`	`""`	Returns the ID number of the current thread. Does not require a specific configuration string. Example: `"" -> [1, 2]`

- Defining sequential specification of the algorithm

Operation execution options

Lincheck provides a set of options for controlling how specific operations are executed, such as running operations on a single thread, executing an operation only once, marking the operation as blocking, and others.

In this article, you will learn about different execution options and how to set them.

Single-thread operation groups

Certain operations are required to never run concurrently, such as operations in single-producer single-consumer queues.

To create a group of operations that are never executed in parallel, use the `nonParallelGroup` option when declaring the operations:

```
@Operation(nonParallelGroup = "consumers")
    fun poll(): Int? = queue.poll()

    @Operation(nonParallelGroup = "consumers")
    fun peek(): Int? = queue.peek()

    @Operation(nonParallelGroup = "producer")
    fun offer(x: Int) = queue.offer(x)

    @Operation
    fun isEmpty(): Boolean = queue.isEmpty()
```

Lincheck ensures that the operations from the non-parallel group are never executed in parallel with each other. However, these operations can still run in parallel with operations outside of the non-parallel group:

```
| ------------------- |
| Thread 1  | Thread 2  |
| ------------------- |
| poll()    | offer(0)  |
| peek()    | offer(0)  |
| poll()    | isEmpty() |
| poll()    | isEmpty() |
| isEmpty() | isEmpty() |
| ------------------- |
```

Single-use operations

Use the `runOnce` option to execute the operation only once per test invocation:

```
@Operation(runOnce = true)
    fun singleOp() = struct.singleOp()

    @Operation
    fun regularOp() = struct.regularOp()
```

An example of a generated scenario:

```
| --------------------------- |
| Thread 1      | Thread 2    |
| --------------------------- |
| regularOp()   | singleOp()  |
| regularOp()   | regularOp() |
| --------------------------- |
```

Blocking operations

Use the `blocking` option if the operation is intended to block the execution. If the test checks for non-blocking guarantees, Lincheck does not fail a test when the execution stalls on an operation marked with the `blocking` option:

```
@Operation(blocking = true)
    fun put(key: Int, value: Int) = map.put(key, value)
```

Cancelable operations

Use the `cancellableOnSuspension` option if the operation can be canceled when it suspends:

```
@Operation(cancellableOnSuspension = true)
    suspend fun receive() = ch.receive()
```

Consider the following channel test:

```
@Param(name = "value", gen = IntGen::class, conf = "1:3")
class CancellableOnSuspensionTest {
    private val ch = Channel<Int>()

    @Operation
    suspend fun send(@Param(name = "value") value: Int) = ch.send(value)

    @Operation(cancellableOnSuspension = true)
    suspend fun receive() = ch.receive()

    @Test
    fun test() = ModelCheckingOptions()
        .iterations(50)
        .invocationsPerIteration(1000)
        // Report the scenarios even if the test has not failed
        .logLevel(LoggingLevel.INFO)
        .check(this::class)
}
```

`cancellableOnSuspension = false`

If `receive()` is suspended, it stays suspended for the rest of the scenario:

```
| ------------------------------ |
|      Thread 1    |      Thread 2 |
| ------------------------------ |
| send(3)          | send(3) + cancel |
| receive()        | send(2) + cancel |
| receive()        | receive()        |
| receive()        | receive()        |
| send(1) + cancel | receive()        |
| ------------------------------ |
```

`cancellableOnSuspension = true`

Lincheck explores the scenarios where `receive()` is suspended and then gets canceled, which better models real-life coroutine code:

```
| ------------------------------------- |
|      Thread 1      |      Thread 2      |
| ------------------------------------- |
| send(3)            | send(3) + cancel   |
| receive() + cancel | send(2) + cancel   |
| receive() + cancel | receive()          |
| receive() + cancel | receive() + cancel |
| send(1) + cancel   | receive() + cancel |
| ------------------------------------- |
```

Prompt cancellation

If `cancellableOnSuspension` is enabled and the operation should support prompt cancellation, you can also set `promptCancellation` to `true`:

```
@Operation(cancellableOnSuspension = true, promptCancellation = true)
    suspend fun receive() = ch.receive()
```

Consider the following channel test:

```
@Param(name = "value", gen = IntGen::class, conf = "1:3")
class PromptCancellationTest {
    private val ch = Channel<Int>()

    @Operation
    suspend fun send(@Param(name = "value") value: Int) = ch.send(value)

    @Operation(cancellableOnSuspension = true, promptCancellation = true)
    suspend fun receive() = ch.receive()

    @Test
    fun test() = ModelCheckingOptions()
        .iterations(50)
        .invocationsPerIteration(1000)
        // Report the scenarios even if the test has not failed
        .logLevel(LoggingLevel.INFO)
        .check(this::class)
}
```

`promptCancellation = false`

Lincheck can only try to cancel the operation after it has actually been suspended. If the operation was resumed before Lincheck attempts cancellation, the cancellation fails and the operation completes normally:

```
| ---------------------------------------
|
|      Thread 1      |      Thread 2
|
| ---------------------------------------
|
| send(2)            | send(2)
|
| send(2) + cancel   | receive() + cancel
|
| receive() + cancel | receive()
|
| receive()          | send(3) + cancel
|
| send(2)            | receive()
|
| ---------------------------------------
|
```

`promptCancellation = true`

Lincheck can cancel the operation even if it has already resumed, but didn't have a chance to run. This models the real-life behavior where a coroutine can be canceled between the moment it is resumed and the moment it actually processes the result:

```
| ------------------------------------------- |
|      Thread 1      |         Thread 2       |
| ------------------------------------------- |
| send(2)            | send(2)                |
| send(2) + cancel   | receive() + cancel     |
| receive() + cancel | receive() + prompt_cancel |
| receive()          | send(3) + cancel       |
| send(2)            | receive()              |
| ------------------------------------------- |
```

Progress guarantees

Many concurrent algorithms provide non-blocking progress guarantees, such as wait-freedom, lock-freedom, or obstruction-freedom.

Lincheck only supports verification of obstruction-freedom. However, because lock-free and wait-free algorithms are also obstruction-free, any violation of obstruction-freedom also indicates a violation of those stronger guarantees.

Use the `checkObstructionFreedom` option to verify the obstruction-freedom guarantee of the program:

```
@Test
    fun modelCheckingTest() = ModelCheckingOptions()
        .checkObstructionFreedom()
        .check(this::class)
```

The `checkObstructionFreedom` option is only available for the model checking strategy.

Lincheck verifies obstruction-freedom by checking whether a thread can make progress when all other threads are paused. If a thread's execution gets stuck in a loop, Lincheck reports an active lock.

If certain functions are intentionally blocking, you can mark them with `@Operation(blocking = true)` to prevent false positives.

Example: test `ConcurrentHashMap` for obstruction-freedom

In this example, you will test the `put()` function of a `ConcurrentHashMap` structure.

1. Create a `ConcurrentHashMapTest.kt` file.
2. Create a test class for `ConcurrentHashMap`, declare the `put()` function and a test function with the `checkObstructionFreedom()` option enabled:

   ```
   class ConcurrentHashMapTest {
       private val map = ConcurrentHashMap<Int, Int>()

       @Operation
       fun put(key: Int, value: Int) = map.put(key, value)

       @Test
       fun modelCheckingTest() = ModelCheckingOptions()
           .checkObstructionFreedom()
           .threads(2)
           .actorsPerThread(1)
           .check(this::class)
   }
   ```

   The `threads` and `actorsPerThread` options are used to reduce the number of potential execution scenarios. These options do not change the pass/fail state of the test, but they significantly reduce the testing time.
3. Run the test. It should fail with the following report:

```
= The algorithm should be non-blocking, but an active lock is detected =
| -------------------- |
| Thread 1  | Thread 2  |
| -------------------- |
| put(1, 0) | put(1, 1) |
| -------------------- |

The following interleaving leads to the error:
| ------------------------------------------------------------------------------------------------------
------------ |
|                                          Thread 1                                                    |
Thread 2      |
| ------------------------------------------------------------------------------------------------------
------------ |
| put(1, 0): <hung>                                                                                    |
|
|   map.put(1, 0)                                                                                      |
|
|     putVal(1, 0, false)                                                                              |
|
|       spread(1): 1                                                                                   |
|
|       table → null                                                                                   |
|
|       loop(1 iterations) at ConcurrentHashMap.putVal(ConcurrentHashMap.java:1016)                    |
|
|         <iteration 1>                                                                                |
|
|           initTable()                                                                                |
|
|             loop(1 iterations) at ConcurrentHashMap.initTable(ConcurrentHashMap.java:2293)           |
|
|             table → null                                                                             |
|
|             switch                                                                                   |
|
|                                                                                                      |
put(1, 1): <hung> |
| ------------------------------------------------------------------------------------------------------
------------ |
```

4. Add the `blocking = true` option to the `put()` function annotation:

```
@Operation(blocking = true)
    fun put(key: Int, value: Int) = map.put(key, value)
```

5. Rerun the test. It should pass successfully.

Example: test `ConcurrentSkipListMap` for obstruction-freedom

In this example, you will test the `put()` function of a non-blocking `ConcurrentSkipListMap` structure.

1. Create a `ConcurrentSkipListMapTest.kt` file.
2. Create a test class for `ConcurrentSkipListMap`, declare the `put()` function and a test function with the `checkObstructionFreedom()` option enabled:

```
class ConcurrentSkipListMapTest {
    private val map = ConcurrentSkipListMap<Int, Int>()

    @Operation
    fun put(key: Int, value: Int) = map.put(key, value)

    @Test
    fun modelCheckingTest() = ModelCheckingOptions()
        .checkObstructionFreedom()
        .check(this::class)
}
```

3. Run the test. It should pass successfully.

Results verification and validation

After executing the scenarios generated for a concurrent data structure, Lincheck verifies the results against the specified verification model (for example, linearizability) and optionally checks the final state of the data structure against the user-provided validation function.

Verification

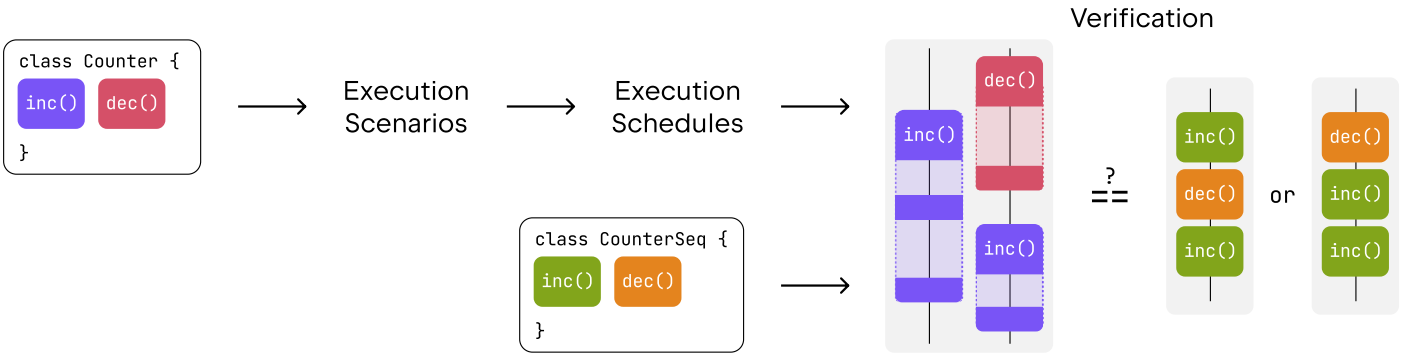
During the verification process, Lincheck tries to find a sequential execution of the operations in the concurrent scenario that achieves the same results as the concurrent execution:

A diagram of the verification process in Lincheck. Lincheck compares a concurrent execution to different sequential executions.

Depending on the verification model, there might be additional restrictions on sequential execution. If no sequential execution matching the verification property can produce the observed results, Lincheck reports an error.

Sequential specification

By default, during the verification process, Lincheck constructs a sequential execution using the operations of the *concurrent* data structure.



You can specify a sequential data structure with matching operations to:

- Make sure that the concurrent data structure provides the same results as the sequential one.

  Typically, single-threaded implementations are simpler than thread-safe implementations, and therefore can be much more easily verified for correctness (for example, `HashMap` and `ConcurrentHashMap`, `LinkedList` and `ConcurrentLinkedQueue`).

  By comparing the execution results of two versions of a structure, you can make sure that the more complex concurrent structure behaves similarly to a simpler structure in a single-threaded environment.

- Verify both sequential correctness and concurrency safety in a single test.

A diagram of the verification process in Lincheck. Lincheck compares a concurrent execution to different sequential executions. Sequential executions use the operations of the specified sequential version of the structure.

To specify a sequential version of a data structure:

1. Implement a data structure with sequential versions of all concurrent functions tested by Lincheck.
2. Specify the data structure using the `sequentialSpecification()` option:

```
@Test
    fun stressTest() = StressOptions()
        .sequentialSpecification(SequentialQueue::class.java)
        .check(this::class)
```

An example of a Lincheck test that uses a single-threaded `LinkedList` as the sequential specification of `ConcurrentLinkedQueue`:

```
class ConcurrentLinkedQueueTest {
    private val s = ConcurrentLinkedQueue<Int>()

    @Operation
    fun add(value: Int) = s.add(value)

    @Operation
    fun poll(): Int? = s.poll()

    @Test
    fun stressTest() = StressOptions()
        .sequentialSpecification(SequentialQueue::class.java)
        .check(this::class)
}

class SequentialQueue {
    private val s = LinkedList<Int>()

    fun add(x: Int) = s.add(x)
    fun poll(): Int? = s.poll()
}
```

Verification models

By default, Lincheck verifies the results of the concurrent execution against the linearizability model. To apply a different verification model, use the `verifier` option:

```
@Test
    fun customVerifierTest() = ModelCheckingOptions()
        .verifier(SerializabilityVerifier::class.java)
        .check(this::class.java)
```

Lincheck provides the following verifier classes:

- `LinearizabilityVerifier` – the default option. Concurrent execution is valid if there is a sequential execution that preserves the "happens-before" relations among the operations in the concurrent execution.
- `QuiescentConsistencyVerifier` – uses the *quiescent consistency* model which works similarly to the linearizability model, but the "happens-before" constraints are not applied to the operations annotated with `@QuiescentConsistent`:

  ```
  @Operation
  @QuiescentConsistent
  fun someOperation() = { ... }
  ```

  > `QuiescentConsistencyVerifier` does not track actual quiescent points. The verifier can potentially miss bugs that occur across the boundaries of quiescent points.

- `SerializabilityVerifier` – uses the *serializability* model where the concurrent execution is valid if there is some sequential execution (in any order) that leads to the same results as the concurrent execution, regardless of the "happens-before" constraints. It can be used for structures where the relative order of concurrent operations does not matter.

Compare serializability and linearizability

To understand the difference between the two models, see how a data structure can be serializable but not linearizable:

1. Consider the following data structure:

```
class ConcurrentQueue {
    private val elements: MutableList<Int> = ArrayList()

    fun put(x: Int) = synchronized(this) {
        elements += x
    }

    fun poll(): Int? = synchronized(this) {
        if (elements.isEmpty()) return null
        elements.shuffle()
        elements.removeAt(0)
    }
}
```

   This concurrent structure behaves incorrectly: it stores elements like in a typical queue, but returns them randomly.

2. Implement a sequential version of the queue that correctly stores and returns the elements:

```
class CorrectSequentialQueue {
    private val elements: MutableList<Int> = ArrayList()

    fun put(x: Int) {
        elements += x
    }

    fun poll(): Int? = if (elements.isEmpty()) null else elements.removeAt(0)
}
```

3. Create a test class and declare the `put()` and `poll()` operations:

```
@Param(name = "value", gen = IntGen::class, conf = "1:2")
class ConcurrentQueueTest {
    private val q = ConcurrentQueue()

    @Operation
    fun put(@Param(name = "value") x: Int) = q.put(x)

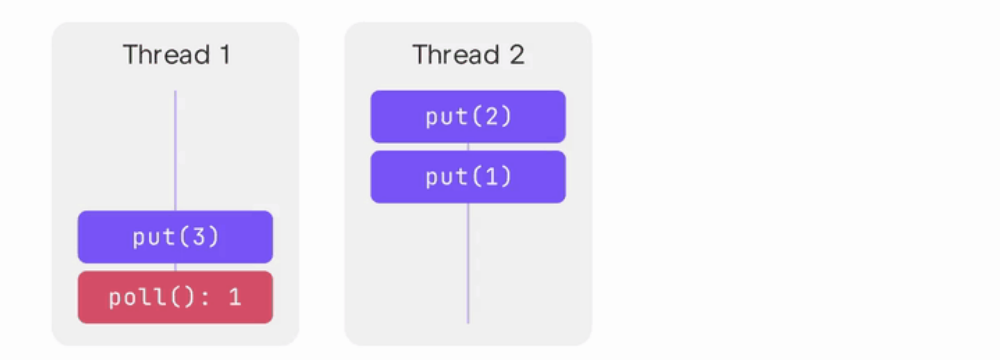
    @Operation
    fun poll(): Int? = q.poll()
}
```

4. Declare and run a serializability test:

```
@Test
    fun serializabilityTest() = ModelCheckingOptions()
        .actorsBefore(0)
        .actorsAfter(0)
        .actorsPerThread(2)
        .threads(2)
        // Use the `SerializabilityVerifier`
        .verifier(SerializabilityVerifier::class.java)
        // Specify the sequential version of the structure
        .sequentialSpecification(CorrectSequentialQueue::class.java)
        .check(this::class.java)
```

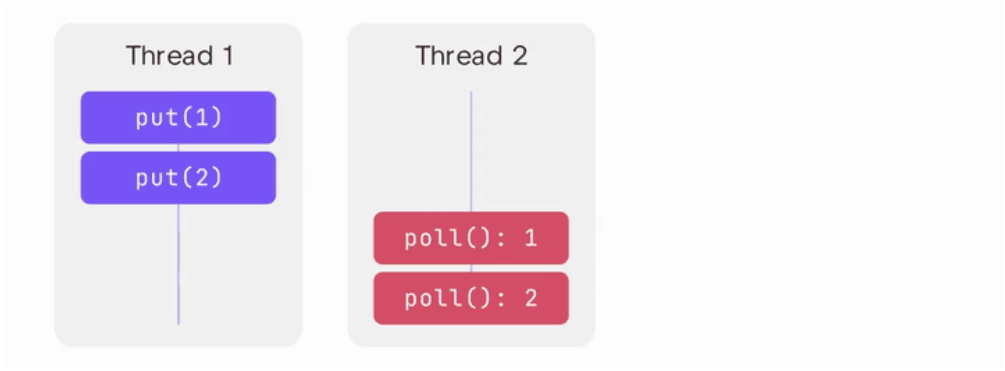
It should pass successfully.

5. Declare and run a linearizability test:



```
@Test
    fun linearizabilityTest() = ModelCheckingOptions()
        .actorsBefore(0)
        .actorsAfter(0)
        .actorsPerThread(2)
        .threads(2)
        // Show the full failed scenario
        .minimizeFailedScenario(false)
        // Specify the sequential version of the structure
        .sequentialSpecification(CorrectSequentialQueue::class.java)
        .check(this::class.java)
```

The test should fail with the following report:



```
| -------------------- |
| Thread 1   | Thread 2 |
| -------------------- |
|            | put(2)   |
|            | put(1)   |
| put(3)     |          |
| poll(): 1  |          |
| -------------------- |
```

6. Analyze the results.

Because the serializability test passes, there exists *some* sequential order of `SequentialQueue` operations that produces `poll(): 1`, for example:

However, linearizability further restricts the operation order: if operation `A` finishes before operation `B` begins in the concurrent execution, then `A` must be executed before `B` in the sequential execution. An example of a linearizable execution would look like this:

Because Lincheck cannot reorder the `put()` operations during verification, it cannot find a sequential execution that complies with linearizability restrictions. This results in a failed test.

Validation

By default, Lincheck does not validate the state of the concurrent data structure after executing a generated scenario. To check the final state, use the `@Validate` annotation on your validation function in the test class:

```
@Validate
    fun validate() {
        // Check some property of the data structure
        // Throw an exception if the check is violated
        check(storage.size ⩾ 2) { "Size must be at least 2, but was ${storage.size}" }
    }
```

The validation function should:

- Accept no arguments.
- Throw an exception if the data structure is in an invalid state.

What's next

- Configuring argument generation constraints
- Configuring operation execution
- Checking for non-blocking progress guarantees

Model checking

To test the code using the model checking strategy, Lincheck inserts explicit thread-switch instructions at points of shared-memory access (`read` and `write`) or at synchronization points, such as lock acquisition and release, `park` / `unpark` , `wait` / `notify` , and others. This approach enables Lincheck to controllably explore the execution schedules of a program and find the ones that lead to incorrect results.

When testing concurrent code using model checking, Lincheck makes sure that the exploration of the execution schedules is:

- Deterministic. Each invocation of a model checking test returns the same result if the input data has not changed.
- Bounded. Each test explores only a limited number of execution schedules. The number of possible execution schedules grows exponentially with the size of the program, and always exploring all of them would significantly increase testing times. You can adjust the limit by changing the value of `invocationsPerIteration`.

Compared to stress testing, model checking enables Lincheck to collect execution traces and guarantees bug reproduction for failed tests. For a more detailed comparison, see the table in the Testing strategies article.

Deterministic exploration

Model checking in Lincheck requires that, given the same input data and execution schedule, the code under test produces the same results. Deterministic execution in model checking is what enables Lincheck to collect execution traces and guarantees bug reproduction for failed tests, which means that any non-deterministic code prevents model checking from working properly.

If an execution produces a non-deterministic result, Lincheck reports an error:

```
Non-determinism found. Probably caused by non-deterministic code (WeakHashMap, Object.hashCode, etc).
== Reporting the first execution without execution trace ==
= Invalid execution results =
| -------- |
| Thread 1 |
| -------- |
| inc(): 2 |
| -------- |

== Reporting the second execution ==
= Invalid execution results =
| -------- |
| Thread 1 |
| -------- |
| inc(): 3 |
| -------- |
```

Some sources of non-determinism are controlled by Lincheck, while others are either restricted for usage or might produce an unexpected test failure.

Controlled sources of non-determinism

When running a test with the model checking strategy, Lincheck controls the following sources of non-determinism:

- **Thread-switching**. Instead of relying on the JVM for thread-switching, Lincheck inserts explicit thread-switch instructions at points of shared-memory access (`read` and `write`) or at synchronization points, such as lock acquisition and release, `park` / `unpark` , `wait` / `notify` , and others.
- **Random number generators**. Lincheck fixes the random seed.
- **Identity hash codes**. Lincheck fixes the identity hash codes of objects.
- **Time API calls**. Lincheck intercepts the time API calls and returns deterministic results.
-

Top-level and `companion object` properties. Lincheck resets the values of top-level `var` properties and `companion object` properties (the Kotlin equivalents of global variables) between invocations in model checking tests:

```
@TestMethodOrder(MethodOrderer.OrderAnnotation::class)
class VariableResetTest {
    companion object {
        private var atomicInt = AtomicInteger(0)
    }

    @Test
    @Order(1)
    fun modelCheckingTest() = Lincheck.runConcurrentTest {
        val t1 = thread { atomicInt.getAndIncrement() }
        val t2 = thread { atomicInt.getAndIncrement() }

        t1.join()
        t2.join()

        check(atomicInt.get() == 2)
    }

    @Test
    @Order(2)
    fun resetAfterModelCheckingTest() {
        // Verify `atomicInt` has been reset to 0 after `modelCheckingTest()`
        check(atomicInt.get() == 0)
    }

    @Test
    @Order(3)
    fun regularIncTest() {
        atomicInt.getAndIncrement()
        check(atomicInt.get() == 1)
    }

    @Test
    @Order(4)
    fun valuePersistsAfterRegularIncTest() {
        // Verify `atomicInt` still holds 1 after `regularIncTest()`
        check(atomicInt.get() == 1)
    }
}
```

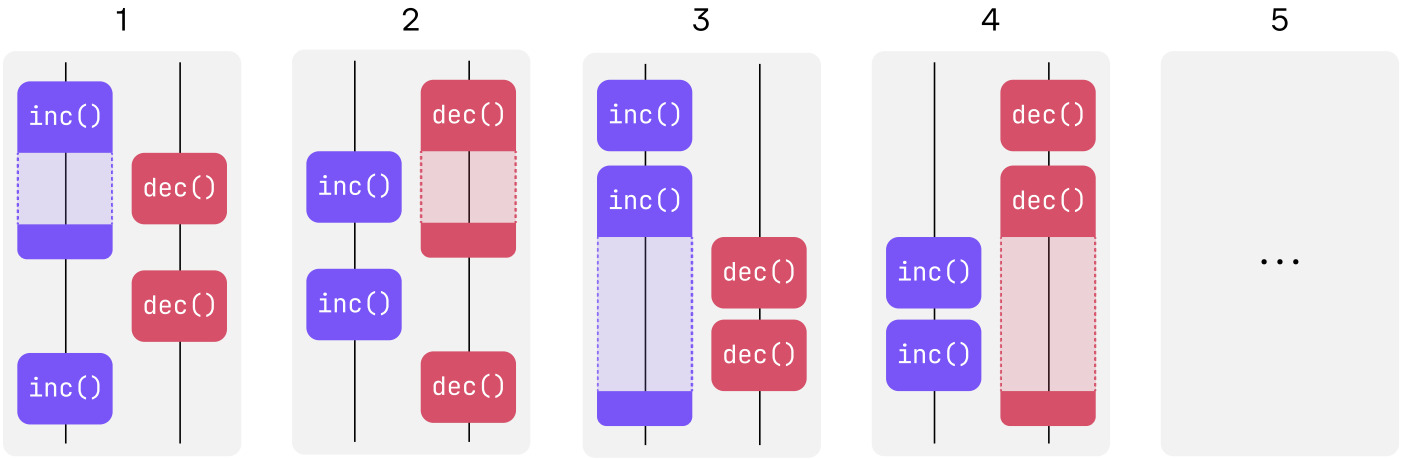
Uncontrolled sources of non-determinism

Lincheck controls some sources of non-determinism, but not all. Using non-deterministic code in a way that Lincheck cannot control either prevents you from using Lincheck with this particular part of code or requires workarounds.

Each uncontrolled source of non-determinism is explained in detail in a dedicated section:

- Thread-local variables
- Weak references
- I/O API calls

Bounded exploration



When testing concurrent code, Lincheck runs each execution scenario multiple times – a different execution schedule of a program is explored in each scenario invocation. Because the number of possible execution schedules grows exponentially with the size of the program, the number of invocations for a single execution scenario test is limited to reduce the testing times. If the number of the invocations required to explore all execution schedules exceeds the specified limit, Lincheck stops the exploration.

When Lincheck is unable to analyze *all* execution schedules, it tries to evenly analyze logically different ones:

- Lincheck first explores all schedules with a single preemptive thread switch, then all schedules with two, and so on.
- When choosing the next schedule to explore, Lincheck prioritizes schedules with thread switches in new locations.

Example: schedules with one thread switch

See how Lincheck models execution schedules with a single preemptive thread switch in a two-thread scenario:

A diagram of four execution schedules modeled by Lincheck for the same two-thread scenario with a single thread switch between threads.

Because Lincheck starts by modeling a schedule with a thread switch in the first thread, the next modeled schedule is more likely to have a thread switch in the second thread. This continues until Lincheck either reaches the limit of explored schedules or exhausts all possible schedules.

Known limitations and workarounds

The model checking strategy has the following known limitations.

Relaxed Java memory model

Model checking requires Lincheck to assume a sequentially consistent memory model of the execution.

The relaxed memory model used in Java can introduce bugs related to instruction reordering, memory cache behavior, and other similar effects. With model checking, Lincheck cannot simulate such effects and catch bugs related to them.

Vote for the related issue and track its progress on GitHub.

Most concurrency bugs can be found even under the assumption of a sequentially consistent memory model. However, Lincheck can miss some bugs caused by low-level effects. For example, a missing `@Volatile` modifier might produce a bug caused by store buffer or a compiler reordering, which cannot be caught by Lincheck's model checker:

```
class RelaxedMemoryModelTest {
    var x = 0 // Not @Volatile
    var y = 0 // Not @Volatile

    @Test
    fun modelCheckingTest() = Lincheck.runConcurrentTest {
        thread {
            x = 1
            y = 1
        }
        thread {
            if (y == 1 && x == 0) {
                // Code in this block might be executed on real hardware because of
                // store buffer and compiler reordering.
                // Lincheck cannot model this behavior with model checking.
                error("Unreachable under sequential consistency")
            }
        }
    }
}
```

Workaround

If you want to test concurrent code without the assumption of a sequentially consistent memory model, Lincheck provides a stress testing strategy for concurrent data structures.

Threads created outside the scenario

Lincheck can only track the threads created inside a concurrent scenario. It can miss bugs occurring in externally created threads, such as when using the default dispatcher with coroutines or the common thread pool with Java's `ForkJoinPool`.

> Vote for the related issue and track its progress on GitHub.

Workaround

Use a fixed thread pool:

- As a local coroutines dispatcher
- Instead of the common thread pool used by `ForkJoinPool`

This guarantees that Lincheck can track the lifecycle and activity of threads in a concurrent scenario:

As a local coroutine dispatcher

```
class FixedThreadPoolDispatcherTest {
    @Test
    fun test() = Lincheck.runConcurrentTest {
        val dispatcher = Executors.newFixedThreadPool(nThreads).asCoroutineDispatcher()
        dispatcher.use {
            runBlocking(dispatcher) {
                val counter = AtomicInteger(0)
                val coro = launch {
                    while (isActive) { counter.getAndIncrement() }
                }
                coro.cancel()
                coro.join()
            }
        }
    }
}
```

Instead of the common thread pool

```
class FixedThreadPoolExecutorServiceTest {
    @Test
    fun test() = Lincheck.runConcurrentTest {
        val executorService = Executors.newFixedThreadPool(nThreads)
        try {
            val counter = AtomicInteger(0)
            val task = Runnable { counter.getAndIncrement() }
            val future1 = executorService.submit(task)
            val future2 = executorService.submit(task)
            future1.get()
            future2.get()
        } finally {
            executorService.shutdown()
        }
    }
}
```

Thread-local variables

Lincheck does not reset thread-local variables during multiple invocations of the same scenario (unlike it does with top-level `var` properties and `companion object` properties). This leads to inconsistencies between the runs of the same test.

Vote for the related issue and track its progress on GitHub.

Example:

```
class ThreadLocalVariableTest {
    @Test
    fun modelCheckingTest() = Lincheck.runConcurrentTest {
        var counter = getLocalCounter()
        var t = thread { counter.getAndIncrement() }
        t.join()
        check(counter.get() == 1)
    }

    private fun getLocalCounter() = localCounter.get()
}

// Using ThreadLocal to create a variable leads to a failed test
private val localCounter: ThreadLocal<AtomicInteger> = ThreadLocal.withInitial {
    AtomicInteger(0)
}
```

This test fails with an error because the value of the counter accumulates across scenario invocations:

```
| ------------------------------------------------------------------------------------- |
|                   Main Thread                    |                Thread 1              |
| ------------------------------------------------------------------------------------- |
| getLocalCounter(): AtomicInteger#1               |                                     |
| thread(block = Lambda#1): Thread#1               |                                     |
| switch (reason: waiting for Thread 1 to finish)  |                                     |
|                                                  | run()                               |
|                                                  |   counter => AtomicInteger#1        |
|                                                  |   AtomicInteger#1.getAndIncrement(): 2 |
| Thread#1.join()                                  |                                     |
| counter.element => AtomicInteger#1               |                                     |
| AtomicInteger#1.get(): 3                         |                                     |
| ------------------------------------------------------------------------------------- |
```

Workaround

Create thread-local variables manually by storing values in a `ConcurrentHashMap` with thread IDs as keys:

```
class ThreadLocalVariableWorkaroundTest {
    var threadLocalCounters = ConcurrentHashMap<Long, AtomicInteger>()

    @Test
    fun modelCheckingTest() = Lincheck.runConcurrentTest {
        var counter = getLocalCounter()
        var t = thread { counter.getAndIncrement() }
        t.join()
        check(counter.get() == 1)
    }

    private fun getLocalCounter() = threadLocalCounters.computeIfAbsent(Thread.currentThread().id) {
        AtomicInteger(0)
    }
}
```

Because `threadLocalCounters` is a top-level `var` property, Lincheck resets it between invocations, avoiding the accumulation problem.

Weak references

Lincheck does not control when a garbage collector removes objects that are only referenced by weak references. Calling `get()` on such objects produces non-deterministic results. The test might pass successfully despite the use of weak references, but if Lincheck encounters an inconsistency between the runs of the same test, it raises a non-determinism error.

Vote for the related issue and track its progress on GitHub.

Time API calls

Lincheck simulates calls of `java.lang.System.nanoTime()` and `java.lang.System.currentTimeMillis()` by always returning a predefined constant to prevent inconsistencies between the runs of the same test.

This approach might not correctly simulate timeouts, elapsed-time comparisons, rate-limiting, or other logic that depends on elapsed time.

Vote for the related issue and track its progress on GitHub.

I/O API calls

Lincheck does not support calls to I/O APIs, including operations on files and sockets, to prevent inconsistencies between the runs of the same test.

Vote for the related issue and track its progress on GitHub.

Calling I/O APIs leads to `java.lang.IllegalStateException`:

```
class FilesCreateTempFileTest {
    @Operation
    fun operation(): List<String> = List(10) {
        val tempFile = Files.createTempFile("test-prefix", ".txt")
        require(Files.exists(tempFile)) { "File was not created: $tempFile" }
        tempFile.toString()
    }

    // The test fails with the following error message:
    // "java.lang.IllegalStateException: File operations are not supported in Lincheck"
    @Test
    fun modelChecking() = ModelCheckingOptions().check(this::class)
}
```

Virtual threads

Support for virtual threads has not been verified and is not guaranteed. Consider using platform threads for scenarios requiring model checking until support is verified.

Lincheck in Kotlin Multiplatform projects

Lincheck can be used with Kotlin Multiplatform to test the code targeting the JVM. This article will guide you through setting up Lincheck tests in a Kotlin Multiplatform project.

You will:

- Set up your project to run Lincheck tests for targets using the JVM.
- Create classes for counter data structures shared between all targets.
- Create tests for the counters shared between all targets and tests specific to the JVM.
- Run the tests.

Set up a project

1. Create a new Kotlin Multiplatform project in IntelliJ IDEA. When creating a project, make sure that:
   - The **Include tests** checkbox is checked.
   - Your project has a JVM-based (a server, desktop, or Android) target. You can verify that your code compiles for the JVM by checking the `shared/build.gradle.kts` or `core/build.gradle.kts` file:

```
kotlin {
    // ...

    jvm()

    // ...

    // If you have an Android target, the use of JVM is
    // configured in the `androidLibrary` section
    androidLibrary {
        // ...

        compilerOptions {
            jvmTarget = JvmTarget.JVM_11
        }

    // ...

    }
}
```

Server/Desktop + Android and **Server/Desktop + Android + iOS** projects

Kotlin currently doesn't support sharing the code between JVM and Android targets. You will not be able to create shared tests for your platforms, but you can still test the code with Lincheck using platform-specific tests.

For more information about the general test setup for Lincheck, read the Getting started with Lincheck article.

2. Set up the tests folder and Lincheck dependency according to the target platforms in your project:

- **Desktop/Android + iOS**
- **Server + iOS, Server + Desktop, Server + Desktop + iOS**

Desktop/Android + iOS

The directory for the platform-specific tests is created by the Kotlin Multiplatform plugin automatically. For example, for a desktop target it is `shared/src/jvmTest/kotlin`.

Add a Lincheck dependency to the platform-specific test source set and a `kotlin.test` dependency to the `commonTest` source set:

Desktop

```
// shared/build.gradle.kts
    kotlin {
        sourceSets {
            commonTest.dependencies {
                implementation(libs.kotlin.test)
            }
            jvmTest {
                implementation("org.jetbrains.lincheck:lincheck:3.7")
            }
        }
    }
```

Android

```
// shared/build.gradle.kts
    kotlin {
        sourceSets {
            commonTest.dependencies {
                implementation(libs.kotlin.test)
            }
            getByName("androidHostTest").dependencies {
                implementation("org.jetbrains.lincheck:lincheck:3.7")
            }
        }
    }
```

Server + iOS, Server + Desktop, Server + Desktop + iOS

1. Create a `core/src/jvmTest/kotlin` directory. Gradle will run the tests in this directory for all platforms that use the JVM.

   Projects with a desktop target also have a `shared/src/jvmTest/kotlin` directory which you can use instead. However, it is recommended to place the code relevant to both the server and desktop/iOS targets in the `core` directory.

   If you have a desktop target and create a `core/src/jvmTest/kotlin` directory, delete the `shared/src/jvmTest/kotlin` directory.

2. Add a Lincheck dependency to the `jvmTest` source set and a `kotlin.test` dependency to the `commonTest` source set:

```
// core/build.gradle.kts
kotlin {
    // ...
    sourceSets {
        // ...
        commonTest.dependencies {
            implementation(libs.kotlin.test)
        }
        jvmTest.dependencies {
            implementation("org.jetbrains.lincheck:lincheck:3.7")
        }
    }
}
```

Create shared classes

Create classes implementing counter data structures that are shared between all targets:

1. Create an `UnsafeCounter.kt` file in the `core/src/commonMain` or `shared/src/commonMain` directory:

```
class UnsafeCounter {
    private var value: Int = 0

    fun inc() = value++

    fun get(): Int = value
}
```

2. Create a `SafeCounter.kt` file in the same directory:

```
import kotlin.concurrent.atomics.AtomicInt
import kotlin.concurrent.atomics.ExperimentalAtomicApi

@OptIn(ExperimentalAtomicApi::class)
class SafeCounter {
    private var value = AtomicInt(0)

    fun inc() = value.addAndFetch(1)

    fun get(): Int = value.load()
}
```

Write shared tests

Write tests that are run for all targets:

1. Create an `UnsafeCounterTest.kt` file in the `core/src/commonTest` or `shared/src/commonTest` directory:

```
import kotlin.test.Test
import kotlin.test.assertEquals

class UnsafeCounterTest {
    @Test
    fun testIncrement() {
        val counter = UnsafeCounter()
        assertEquals(0, counter.get(), "Initial value should be 0")
        counter.inc()
        assertEquals(1, counter.get(), "Value after one increment should be 1")
    }
}
```

2. Create a `SafeCounterTest.kt` file in the same directory:

```
import kotlin.test.Test
import kotlin.test.assertEquals

class SafeCounterTest {
    @Test
    fun testIncrement() {
        val counter = SafeCounter()
        assertEquals(0, counter.get(), "Initial value should be 0")
        counter.inc()
        assertEquals(1, counter.get(), "Value after one increment should be 1")
    }
}
```

Write JVM-specific tests

Write tests that are only run for platforms targeting the JVM:

1. Create an `UnsafeCounterConcurrentTest.kt` file in the test directory for JVM-specific tests:
   - Android + iOS – `shared/src/androidHostTest/kotlin`
   - Desktop + iOS – `shared/src/jvmTest/kotlin`
   - Any project with a server target – `core/src/jvmTest/kotlin`

```
import org.jetbrains.lincheck.datastructures.ModelCheckingOptions
import org.jetbrains.lincheck.datastructures.Operation
import kotlin.test.Test

class UnsafeCounterConcurrentTest {
    private val c = UnsafeCounter()

    @Operation
    fun inc() = c.inc()

    @Operation
    fun get() = c.get()

    @Test
    fun modelCheckingTest() {
        ModelCheckingOptions().check(this::class)
    }
}
```

2. Create a `SafeCounterConcurrentTest.kt` file in the same directory:

```
import org.jetbrains.lincheck.datastructures.ModelCheckingOptions
import org.jetbrains.lincheck.datastructures.Operation
import kotlin.test.Test

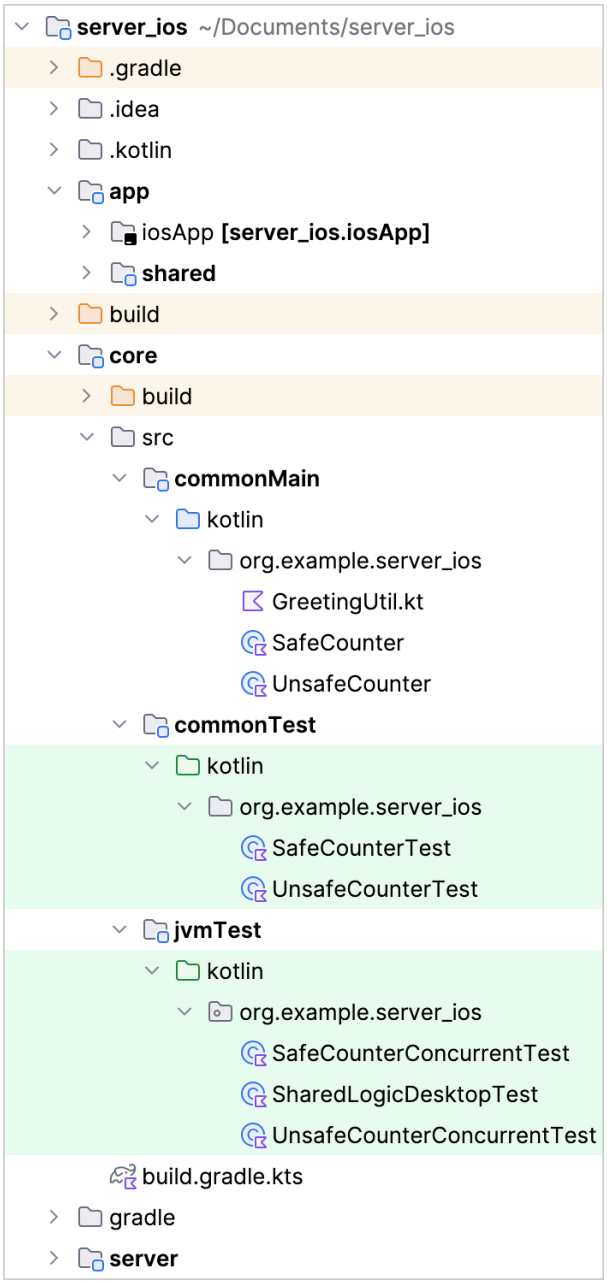
class SafeCounterConcurrentTest {
    private val c = SafeCounter()

    @Operation
    fun inc() = c.inc()

    @Operation
    fun get() = c.get()

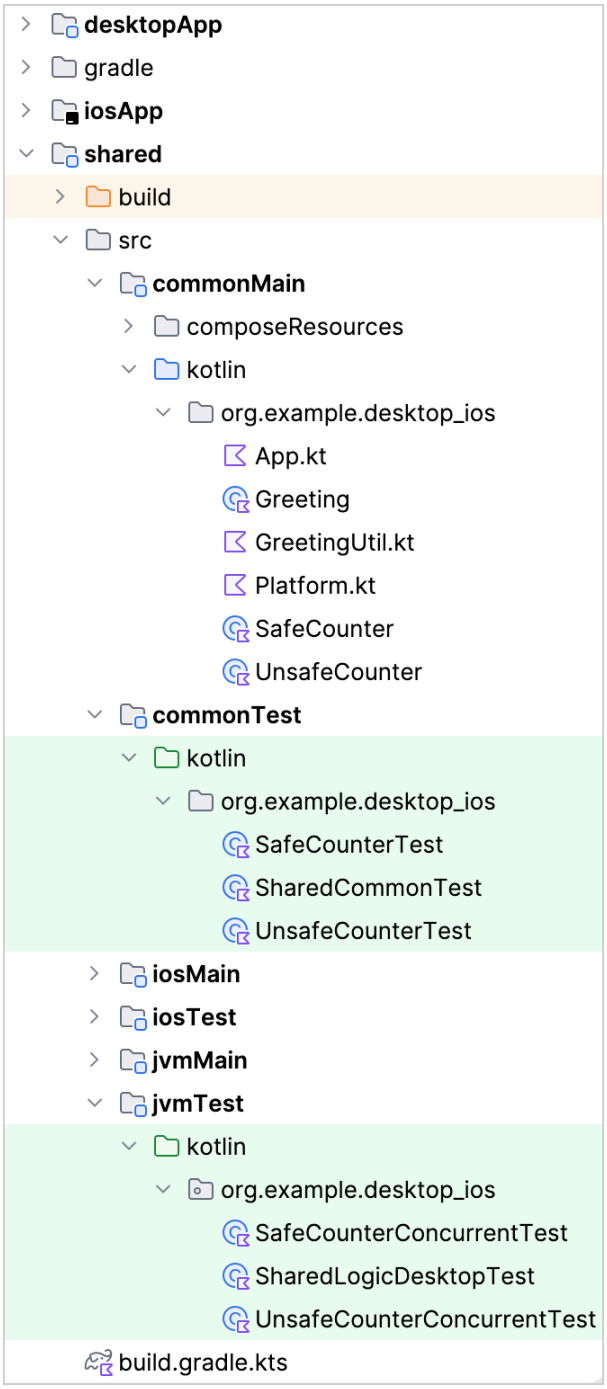
    @Test
    fun modelCheckingTest() {
        ModelCheckingOptions().check(this::class)
    }
}
```

Run the tests



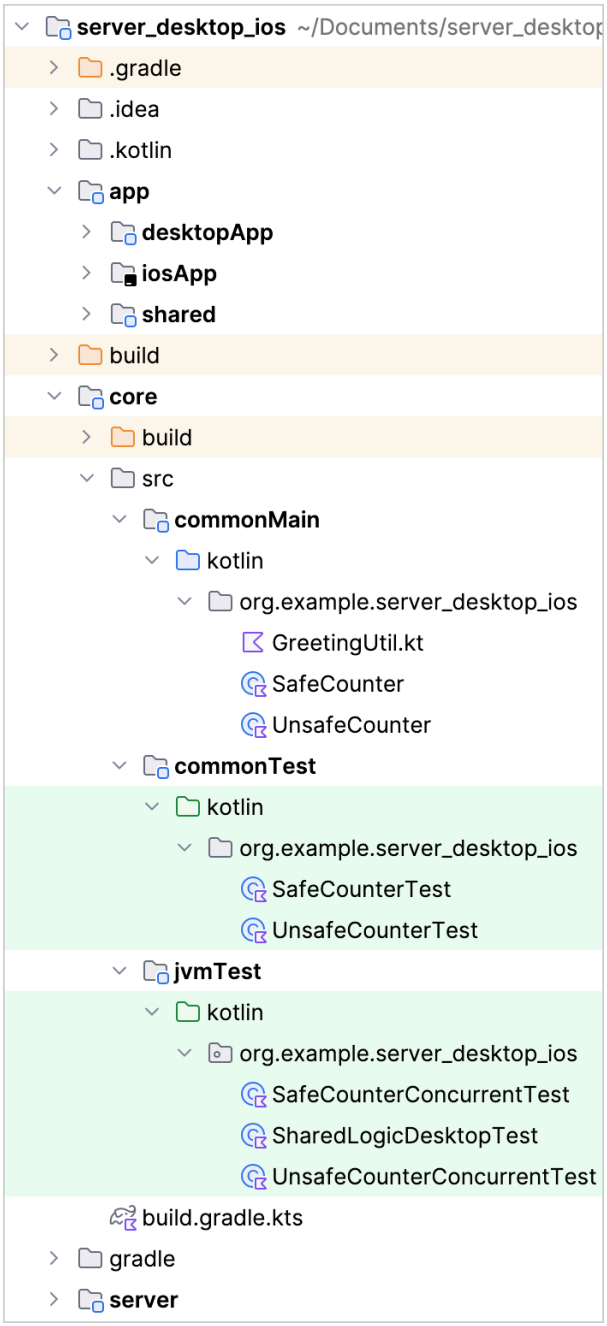
At this point, your project should have the shared implementation of the counter data structures, the shared tests, and the JVM-specific tests for counters. The directory structure of your project should look like this:

Android + iOS



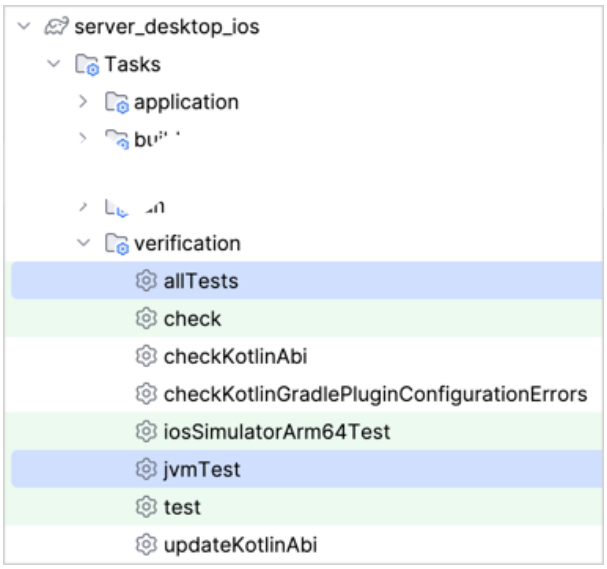
A screenshot of the project file structure for the Android and iOS platforms.

Server + iOS



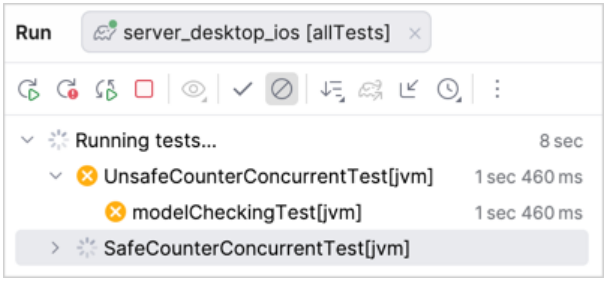
A screenshot of the project file structure for the server and iOS platforms.

Desktop + iOS



A screenshot of the project file structure for the desktop and iOS platforms.

Server + Desktop + iOS



A screenshot of the project file structure for the server, desktop, and iOS platforms.

You can run individual tests from the context menu, using the shortcut, or by running a Gradle task. If you run the `allTests` Gradle task, every test in your project will be executed with the corresponding test runner:

A screenshot of the Gradle plugin in IntelliJ IDEA with the Tasks | Verification | allTests task highlighted.

For example, the JVM-specific tests are executed with the JVM test runner:

A screenshot of the test execution report. The Lincheck tests are marked with a jvm tag.

Support for platforms other than the JVM

Lincheck is unlikely to support other platforms in the future.

Lincheck relies heavily on JVM for bytecode manipulation, which makes model checking challenging to implement on other platforms. Moreover, using model checking for multiple platforms at the same time provides little value because Lincheck tests the code in a deterministic sandbox environment, and the results of the tests will be the same regardless of the platform.

API references

Welcome to the Kotlin API References page. Here you'll find links to the API documentation for the official Kotlin libraries and tools.

If you're looking for Kotlin Multiplatform libraries, browse them on klibs.io.

Standard library (stdlib)

The Kotlin Standard library provides core functionality for Kotlin programming, including essential APIs such as collections, text and string processing, ranges, sequences, and more. It extends platform-specific APIs and provides a Kotlin-first API for working with them.

kotlin

Test library (kotlin.test)

A multiplatform testing library that provides common testing annotations and utility functions. It supports integration with popular test frameworks on each platform and offers a unified testing experience across the Kotlin ecosystem.

kotlin

Coroutines (kotlinx.coroutines)

A powerful library for asynchronous programming using Kotlin coroutines. It offers tools to support structured concurrency, asynchronous streams, synchronization primitives like mutexes and semaphores, testing, and more.

kotlinx.coroutines

Serialization (kotlinx.serialization)

A multiplatform serialization library. It provides a type-safe, compile-time mechanism for converting Kotlin objects to and from a variety of formats such as JSON, CBOR, and Protocol Buffers.

kotlinx.serialization

Kotlin I/O library (kotlinx-io)

A multiplatform library for low-level I/O operations. It defines abstractions for reading from and writing to binary streams and buffers, designed to be efficient and portable across all Kotlin platforms.

kotlinx-io

Date and time (kotlinx-datetime)

A multiplatform library for calendar-based computations. It provides representations of date values and supports timezone-specific operations.

kotlinx-datetime

Immutable collections (kotlinx.collections.immutable)

A multiplatform library providing immutable and persistent collection interfaces and implementations. It offers efficient copy-on-write operations that share structure between versions, so updating a collection doesn't copy the whole thing.

kotlinx.collections.immutable

Kotlin Gradle plugins (kotlin-gradle-plugin)

The Kotlin Gradle plugins for compiling, testing, and packaging Kotlin code. These plugins simplify JVM and multiplatform builds, manage dependencies, and integrate with IDEs and CI systems.

kotlin-gradle-plugin

Ktor

A framework for building asynchronous clients and servers in connected systems using Kotlin. Ktor is designed for scalability and flexibility and is deeply integrated with coroutines for non-blocking I/O and structured concurrency.

ktor

JVM Metadata (kotlin-metadata-jvm)

A library for reading and writing Kotlin metadata stored in JVM class files. It is primarily used by tools such as annotation processors, static analyzers, and compiler plugins.

kotlinx-metadata

Compose Multiplatform Material3

A multiplatform library for building user interfaces with Material Design 3 components. The API reference includes a gallery of Material 3 components where you can preview the composables.

compose-material3

Gradle

Gradle is a build system that helps to automate and manage your building process. It downloads required dependencies, packages your code, and prepares it for compilation. Learn about Gradle basics and specifics on the Gradle website.

You can set up your own project with these instructions for different platforms or pass a small step-by-step tutorial that will show you how to create a simple backend "Hello World" application in Kotlin.

> You can find information about the compatibility of Kotlin, Gradle, and Android Gradle plugin versions here.

In this chapter, you can also learn about:

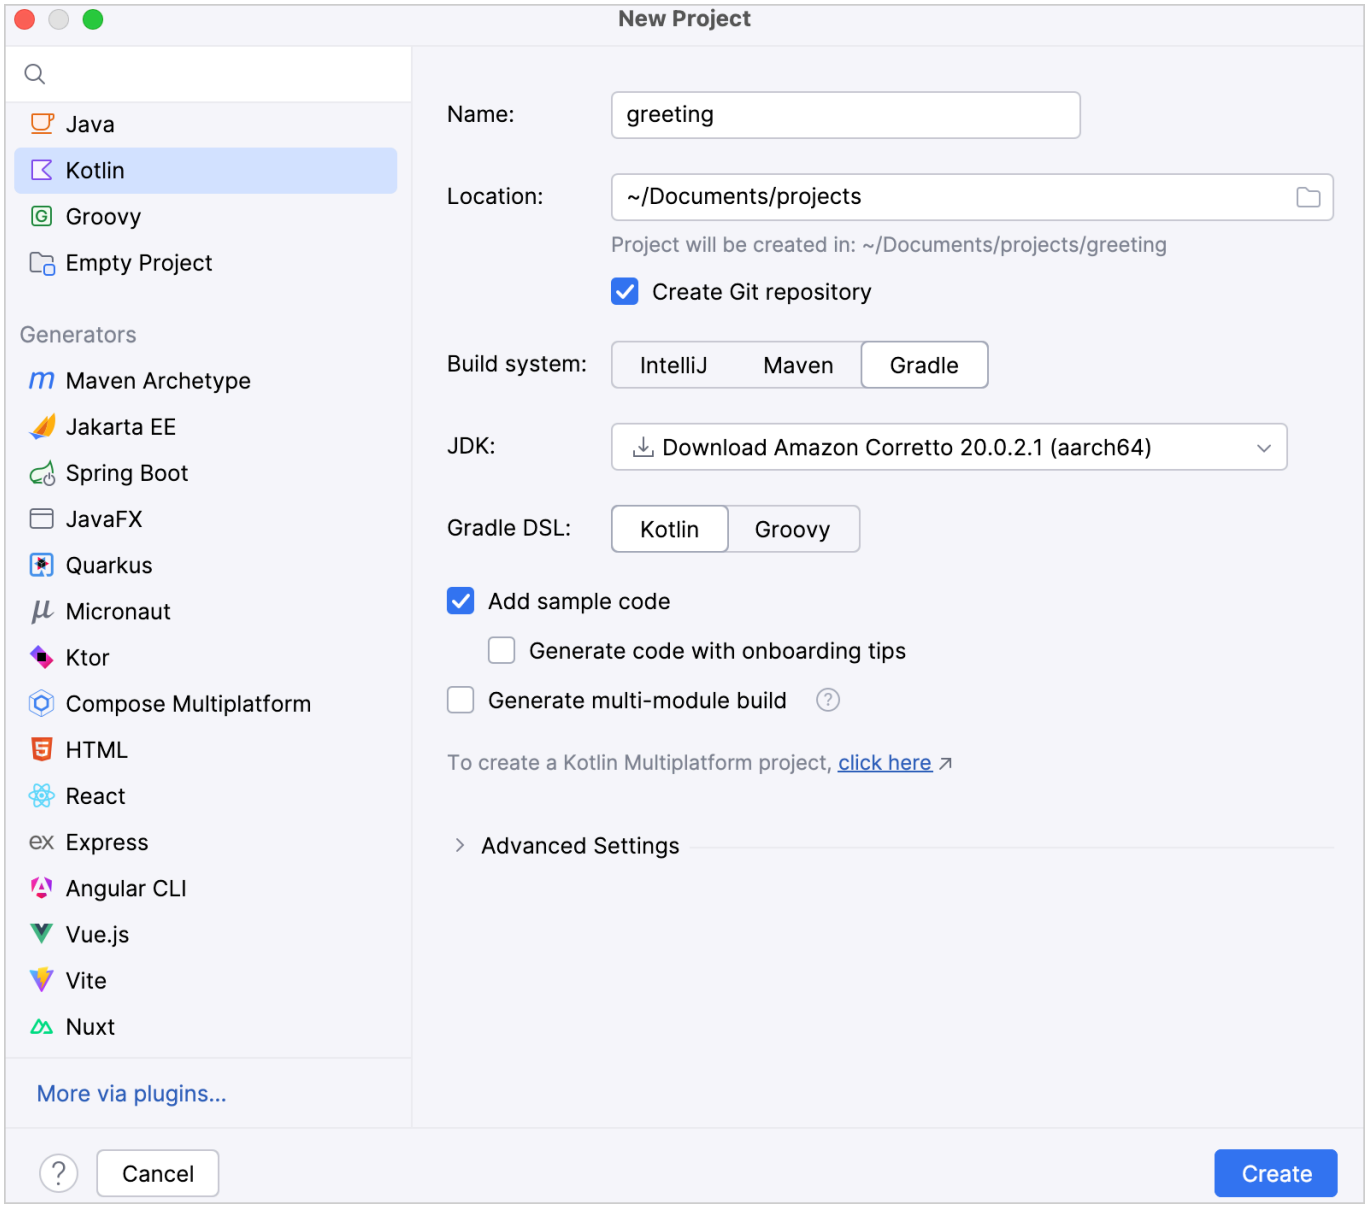
- Compiler options and how to pass them.
- Incremental compilation, caches support, build reports, and the Kotlin daemon.
- Support for Gradle plugin variants.

What's next?

Learn about:

- **Gradle Kotlin DSL**. The Gradle Kotlin DSL is a domain specific language that you can use to write build scripts quickly and efficiently.
- **Annotation processing**. Kotlin supports annotation processing via the Kotlin Symbol processing API.
- **Generating documentation**. To generate documentation for Kotlin projects, use Dokka; please refer to the Dokka README for configuration instructions. Dokka supports mixed-language projects and can generate output in multiple formats, including standard Javadoc.
- **OSGi**. For OSGi support, see the Kotlin OSGi page.

Get started with Gradle and Kotlin/JVM



This tutorial demonstrates how to use IntelliJ IDEA and Gradle to create a JVM console application.

To get started, first download and install the latest version of IntelliJ IDEA.

Create a project

1. In IntelliJ IDEA, select **File** | **New** | **Project**.
2. In the panel on the left, select **Kotlin**.
3. Name the new project and change its location, if necessary.

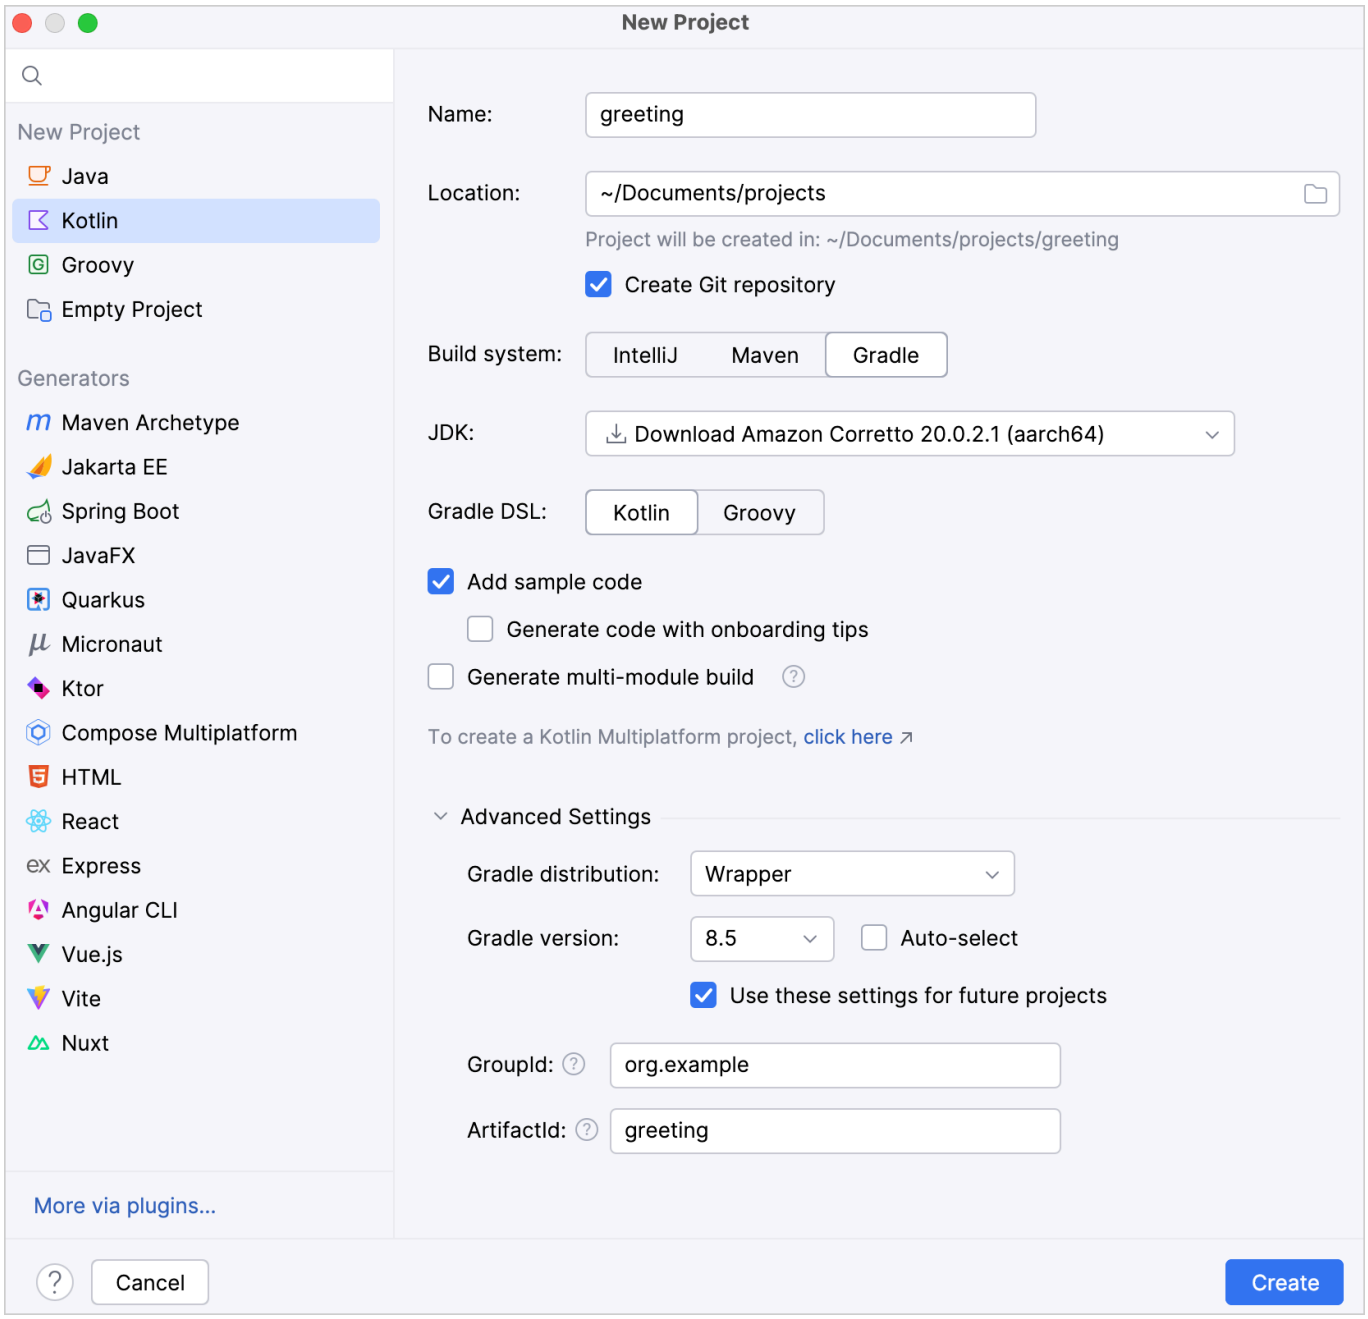
> Select the **Create Git repository** checkbox to place the new project under version control. You will be able to do it later at any time.

Create a console application

4. Select the **Gradle** build system.

5. From the **JDK** list, select the JDK that you want to use in your project.
    - If the JDK is installed on your computer, but not defined in the IDE, select **Add JDK** and specify the path to the JDK home directory.
    - If you don't have the necessary JDK on your computer, select **Download JDK**.
6. Select the **Kotlin** DSL for Gradle.
7. Select the **Add sample code** checkbox to create a file with a sample `"Hello World!"` application.

    > You can also enable the **Generate code with onboarding tips** option to add some additional useful comments to your sample code.



8. Click **Create**.

You have successfully created a project with Gradle!

Specify a Gradle version for your project

You can explicitly specify a Gradle version for your project under the **Advanced Settings** section, either by using the Gradle Wrapper or a local installation of Gradle:

- **Gradle Wrapper:**
    1. From the **Gradle distribution** list, select **Wrapper**.
    2. Disable the **Auto-select** checkbox.
    3. From the **Gradle version** list, select your Gradle version.
- **Local installation:**
    1. From the **Gradle distribution** list, select **Local installation**.
    2. For **Gradle location**, specify the path of your local Gradle version.

Advanced settings

Explore the build script

Open the `build.gradle.kts` file. This is the Gradle Kotlin build script, which contains Kotlin-related artifacts and other parts required for the application:

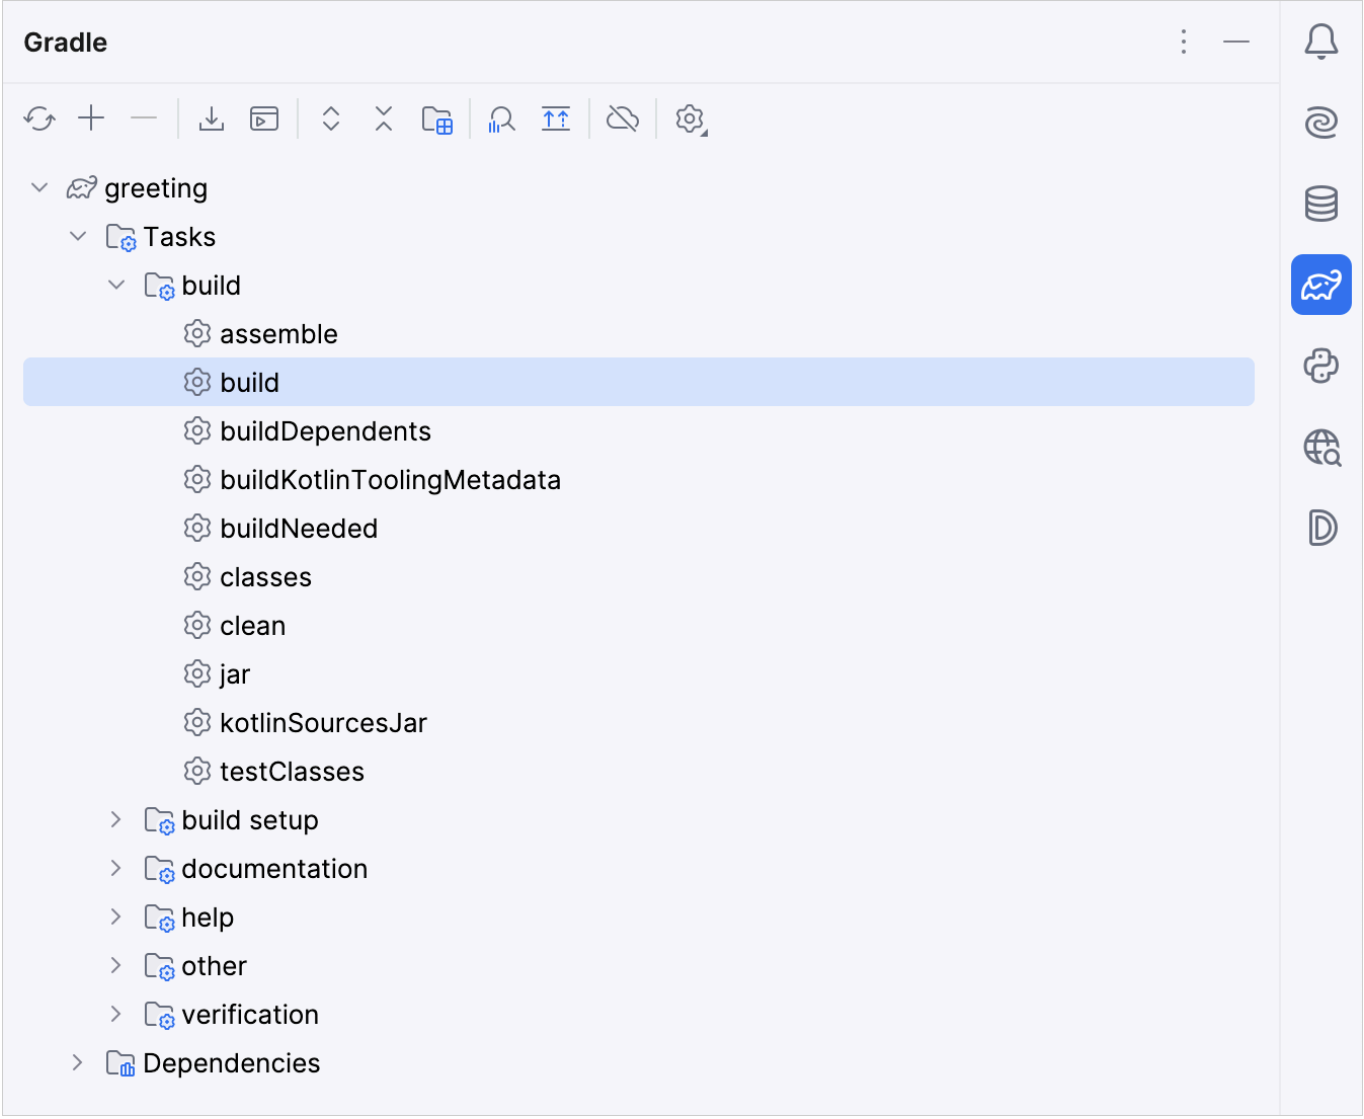
```
plugins {
    kotlin("jvm") version "2.4.20" // Kotlin version to use
}

group = "org.example" // A company name, for example, `org.jetbrains`
version = "1.0-SNAPSHOT" // Version to assign to the built artifact

repositories { // Sources of dependencies. See 1️⃣
    mavenCentral() // Maven Central Repository. See 2️⃣
}

dependencies { // All the libraries you want to use. See 3️⃣
    // Copy dependencies' names after you find them in a repository
    testImplementation(kotlin("test")) // The Kotlin test library
}

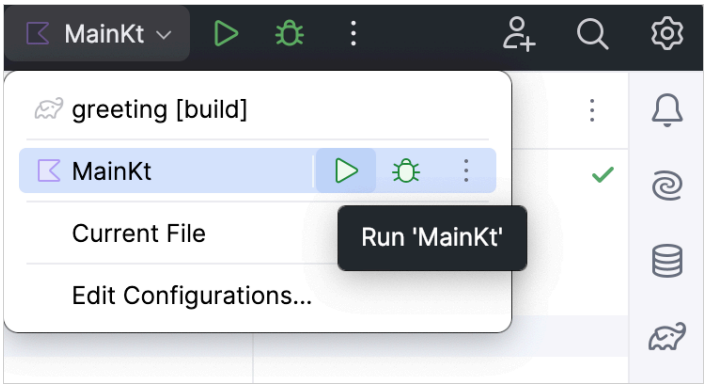
tasks.test { // See 4️⃣
    useJUnitPlatform() // JUnitPlatform for tests. See 5️⃣
}
```



- 1️⃣ Lean more about sources of dependencies.
- 2️⃣ The Maven Central Repository. It can also be Google's Maven repository or your company's private repository.
- 3️⃣ Learn more about declaring dependencies.
- 4️⃣ Learn more about tasks.
- 5️⃣ JUnitPlatform for tests.

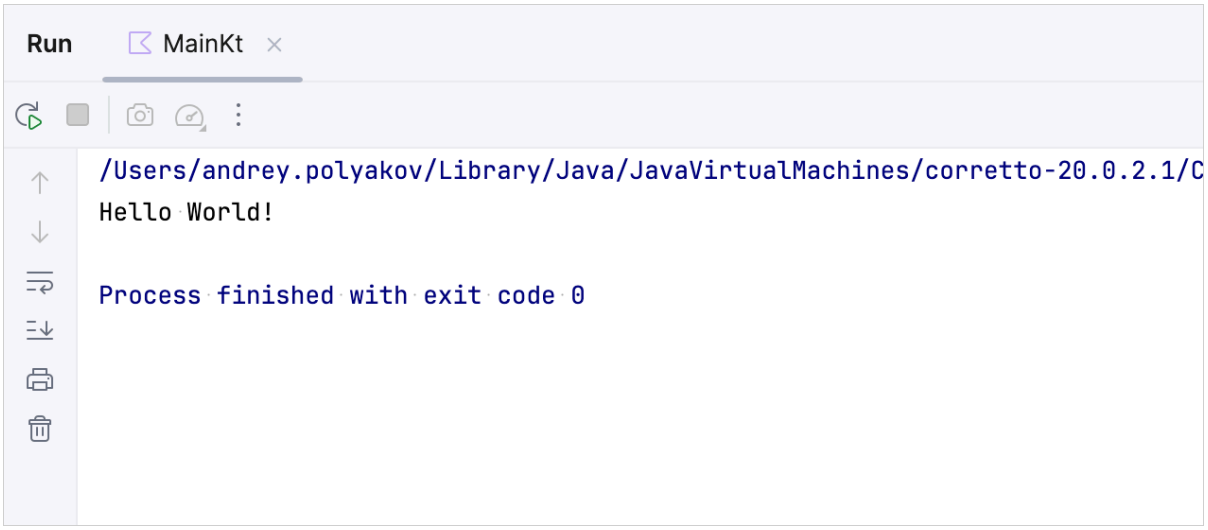
As you can see, there are a few Kotlin-specific artifacts added to the Gradle build file:

1. In the `plugins {}` block, there is the `kotlin("jvm")` artifact. This plugin defines the version of Kotlin to be used in the project.
2. In the `dependencies {}` block, there is `testImplementation(kotlin("test"))`. Learn more about setting dependencies on test libraries.



Run the application

1. Open the Gradle window by selecting **View** | **Tool Windows** | **Gradle**:



Main.kt with main fun

2. Execute the **build** Gradle task in `Tasks\build\`. In the **Build** window, `BUILD SUCCESSFUL` appears. It means that Gradle built the application successfully.
3. In `src/main/kotlin`, open the `Main.kt` file:
   - `src` directory contains Kotlin source files and resources.
   - `Main.kt` file contains sample code that will print `Hello World!`.
4. Run the application by clicking the green **Run** icon in the gutter and select **Run 'MainKt'**.

Running a console app

You can see the result in the **Run** tool window:

Kotlin run output

Congratulations! You have just run your first Kotlin application.

What's next?

Learn more about:

- Gradle build file properties.
- Targeting different platforms and setting library dependencies.
- Compiler options and how to pass them.
- Incremental compilation, caches support, build reports, and the Kotlin daemon.

Configure a Gradle project

To build a Kotlin project with Gradle, you need to add the Kotlin Gradle plugin to your build script file `build.gradle(.kts)` and configure the project's dependencies there.

To learn more about the contents of a build script, visit the Explore the build script section.

Apply the plugin

To apply the Kotlin Gradle plugin, use the `plugins{}` block from the Gradle plugins DSL:

Kotlin

```
plugins {
    // Replace `<...>` with the plugin name appropriate for your target environment
    kotlin("<...>") version "2.4.20"
    // For example, if your target environment is JVM:
    // kotlin("jvm") version "2.4.20"
}
```

Groovy

```
plugins {
    // Replace `<...>` with the plugin name appropriate for your target environment
    id 'org.jetbrains.kotlin.<...>' version '2.4.20'
    // For example, if your target environment is JVM:
    // id 'org.jetbrains.kotlin.jvm' version '2.4.20'
}
```

The Kotlin Gradle plugin (KGP) and Kotlin share the same version numbering.

When configuring your project, check the Kotlin Gradle plugin (KGP) compatibility with available Gradle versions. In the following table, there are the minimum and maximum **fully supported** versions of Gradle and Android Gradle plugin (AGP):

KGP version	Gradle min and max versions	AGP min and max versions
2.4.20	7.6.3–9.7.0	8.5.2–9.3.1
2.4.0-2.4.10	7.6.3–9.5.0	8.5.2–9.1.0
2.3.20–2.3.21	7.6.3–9.3.0	8.2.2–9.0.0
2.3.10	7.6.3–9.0.0	8.2.2–9.0.0
2.3.0	7.6.3–9.0.0	8.2.2–8.13.0
2.2.20–2.2.21	7.6.3–8.14	7.3.1–8.11.1
2.2.0–2.2.10	7.6.3–8.14	7.3.1–8.10.0
2.1.20–2.1.21	7.6.3–8.12.1	7.3.1–8.7.2
2.1.0–2.1.10	7.6.3–8.10*	7.3.1–8.7.2
2.0.20–2.0.21	6.8.3–8.8*	7.1.3–8.5

KGP version	Gradle min and max versions	AGP min and max versions
2.0.0	6.8.3–8.5	7.1.3–8.3.1
1.9.20–1.9.25	6.8.3–8.1.1	4.2.2–8.1.0

*Kotlin 2.0.20–2.0.21 and Kotlin 2.1.0–2.1.10 are fully compatible with Gradle up to 8.6. Gradle versions 8.7–8.10 are also supported, with only one exception: If you use the Kotlin Multiplatform Gradle plugin, you may see deprecation warnings in your multiplatform projects calling the `withJava()` function in the JVM target. For more information, see Java source sets created by default.

You can also use Gradle and AGP versions up to the latest releases, but if you do, keep in mind that you might encounter deprecation warnings or some new features might not work.

For example, the Kotlin Gradle plugin and the `kotlin-multiplatform` plugin 2.4.20 require the minimum Gradle version of 7.6.3 for your project to compile.

Similarly, the maximum fully supported version is 9.7.0. It doesn't have deprecated Gradle methods and properties, and supports all the current Gradle features.

Earlier KGP versions

KGP version	Gradle min and max versions	AGP min and max versions
1.9.0–1.9.10	6.8.3–7.6.0	4.2.2–7.4.0
1.8.20–1.8.22	6.8.3–7.6.0	4.1.3–7.4.0
1.8.0–1.8.11	6.8.3–7.3.3	4.1.3–7.2.1
1.7.20–1.7.22	6.7.1–7.1.1	3.6.4–7.0.4
1.7.0–1.7.10	6.7.1–7.0.2	3.4.3–7.0.2
1.6.20–1.6.21	6.1.1–7.0.2	3.4.3–7.0.2

Kotlin Gradle plugin data in a project

By default, the Kotlin Gradle plugin stores persistent project-specific data at the root of the project, in the `.kotlin` directory.

Do not commit the `.kotlin` directory to version control. For example, if you are using Git, add `.kotlin` to your project's `.gitignore` file.

There are properties you can add to the `gradle.properties` file of your project to configure this behavior:

Gradle property	Description
`kotlin.project.persistent.dir`	Configures the location where your project-level data is stored. Default: `<project-root-directory>/.kotlin`
`kotlin.project.persistent.dir.gradle.disableWrite`	Controls whether writing Kotlin data to the `.gradle` directory is disabled (for backward compatibility with older IDEA versions). Default: false

Targeting the JVM

To target the JVM, apply the Kotlin JVM plugin.

Kotlin

```
plugins {
    kotlin("jvm") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.jvm" version "2.4.20"
}
```

The `version` should be literal in this block, and it cannot be applied from another build script.

Kotlin and Java sources

Kotlin sources and Java sources can be stored in the same directory, or they can be placed in different directories.

The default convention is to use different directories:

```
project
    - src
        - main (root)
            - kotlin
            - java
```

Do not store Java `.java` files in the `src/*/kotlin` directory, as the `.java` files will not be compiled.

Instead, you can use `src/main/java`.

The corresponding `sourceSets` property should be updated if you are not using the default convention:

Kotlin

```
sourceSets.main {
    java.srcDirs("src/main/myJava", "src/main/myKotlin")
}
```

Groovy

```
sourceSets {
    main.kotlin.srcDirs += 'src/main/myKotlin'
    main.java.srcDirs += 'src/main/myJava'
}
```

Check for JVM target compatibility of related compile tasks

In the build module, you may have related compile tasks, for example:

- `compileKotlin` and `compileJava`
- `compileTestKotlin` and `compileTestJava`

`main` and `test` source set compile tasks are not related.

For related tasks like these, the Kotlin Gradle plugin checks for JVM target compatibility. Different values of the `jvmTarget` attribute in the `kotlin` extension or task and `targetCompatibility` in the `java` extension or task cause JVM target incompatibility. For example: the `compileKotlin` task has `jvmTarget=1.8`, and the `compileJava` task has (or inherits) `targetCompatibility=15`.

Configure the behavior of this check for the whole project by setting the `kotlin.jvm.target.validation.mode` property in the `gradle.properties` file to:

- `error` – the plugin fails the build; the default value for projects on Gradle 8.0+.
- `warning` – the plugin prints a warning message; the default value for projects on Gradle less than 8.0.
- `ignore` – the plugin skips the check and doesn't produce any messages.

You can also configure it at task level in your `build.gradle(.kts)` file:

Kotlin

```
tasks.withType<org.jetbrains.kotlin.gradle.tasks.KotlinJvmCompile>().configureEach {
    jvmTargetValidationMode.set(org.jetbrains.kotlin.gradle.dsl.jvm.JvmTargetValidationMode.WARNING)
}
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.tasks.KotlinJvmCompile.class).configureEach {
    jvmTargetValidationMode = org.jetbrains.kotlin.gradle.dsl.jvm.JvmTargetValidationMode.WARNING
}
```

To avoid JVM target incompatibility, configure a toolchain or align JVM versions manually.

What can go wrong if targets are incompatible

There are two ways of manually setting JVM targets for Kotlin and Java source sets:

- The implicit way via setting up a Java toolchain.
- The explicit way via setting the `jvmTarget` attribute in the `kotlin` extension or task and `targetCompatibility` in the `java` extension or task.

JVM target incompatibility occurs if you:

- Explicitly set different values of `jvmTarget` and `targetCompatibility`.
- Have a default configuration, and your JDK is not equal to `1.8`.

Let's consider a default configuration of JVM targets when you have only the Kotlin JVM plugin in your build script and no additional settings for JVM targets:

Kotlin

```
plugins {
    kotlin("jvm") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.jvm" version "2.4.20"
}
```

When there is no explicit information about the `jvmTarget` value in the build script, its default value is `null`, and the compiler translates it to the default value `1.8`. The `targetCompatibility` equals the current Gradle's JDK version, which is equal to your JDK version (unless you use a Java toolchain approach). Assuming that your JDK version is `17`, your published library artifact will declare itself compatible with JDK 17+: `org.gradle.jvm.version=17`, which is wrong. In this case, you have to use Java 17 in your main project to add this library, even though the bytecode's version is `1.8`. Configure a toolchain to solve this issue.

Gradle Java toolchains support

A warning for Android users. To use Gradle toolchain support, use the Android Gradle plugin (AGP) version 8.1.0-alpha09 or higher.

Gradle Java toolchain support is available only from AGP 7.4.0. Nevertheless, because of this issue, AGP did not set `targetCompatibility` to be equal to the toolchain's JDK until the version 8.1.0-alpha09. If you use versions less than 8.1.0-alpha09, you need to configure `targetCompatibility` manually via `compileOptions`. Replace the placeholder `<MAJOR_JDK_VERSION>` with the JDK version you would like to use:

```
android {
    compileOptions {
        sourceCompatibility = <MAJOR_JDK_VERSION>
        targetCompatibility = <MAJOR_JDK_VERSION>
    }
}
```

Gradle 6.7 introduced Java toolchains support. Using this feature, you can:

- Use a JDK and a JRE that are different from the ones in Gradle to run compilations, tests, and executables.
- Compile and test code with a not-yet-released language version.

With toolchains support, Gradle can autodetect local JDKs and install missing JDKs that Gradle requires for the build. Now Gradle itself can run on any JDK and still reuse the remote build cache feature for tasks that depend on a major JDK version.

The Kotlin Gradle plugin supports Java toolchains for Kotlin/JVM compilation tasks. JS and Native tasks don't use toolchains. The Kotlin compiler always runs on the JDK the Gradle daemon is running on. A Java toolchain:

- Sets the `-jdk-home` option available for JVM targets.
- Sets the `compilerOptions.jvmTarget` to the toolchain's JDK version if the user doesn't set the `jvmTarget` option explicitly. If the user doesn't configure the toolchain, the `jvmTarget` field uses the default value. Learn more about JVM target compatibility.
- Sets the toolchain to be used by any Java compile, test, and javadoc tasks.
- Affects which JDK `kapt` workers are running on.

Use the following code to set a toolchain. Replace the placeholder `<MAJOR_JDK_VERSION>` with the JDK version you would like to use:

Kotlin

```
kotlin {
    jvmToolchain {
        languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>))
    }
    // Or shorter:
    jvmToolchain(<MAJOR_JDK_VERSION>)
    // For example:
    jvmToolchain(17)
}
```

Groovy

```
kotlin {
    jvmToolchain {
        languageVersion = JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)
    }
    // Or shorter:
    jvmToolchain(<MAJOR_JDK_VERSION>)
    // For example:
    jvmToolchain(17)
}
```

Note that setting a toolchain via the `kotlin` extension updates the toolchain for Java compile tasks as well.

You can set a toolchain via the `java` extension, and Kotlin compilation tasks will use it:

Kotlin

```
java {
    toolchain {
        languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>))
    }
}
```

Groovy

```
java {
    toolchain {
        languageVersion = JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)
    }
}
```

If you use Gradle 8.0.2 or higher, you also need to add a toolchain resolver plugin. This type of plugin manages which repositories to download a toolchain from. As an example, add to your `settings.gradle(.kts)` the following plugin:

Kotlin

```
plugins {
    id("org.gradle.toolchains.foojay-resolver-convention") version("1.0.0")
}
```

Groovy

```
plugins {
    id 'org.gradle.toolchains.foojay-resolver-convention' version '1.0.0'
}
```

Check that the version of `foojay-resolver-convention` corresponds to your Gradle version on the Gradle site.

To understand which toolchain Gradle uses, run your Gradle build with the log level `--info` and find a string in the output starting with `[KOTLIN] Kotlin compilation 'jdkHome' argument:`. The part after the colon will be the JDK version from the toolchain.

To set any JDK (even local) for a specific task, use the Task DSL.

Learn more about Gradle JVM toolchain support in the Kotlin plugin.

Set JDK version with the Task DSL

The Task DSL allows setting any JDK version for any task implementing the `UsesKotlinJavaToolchain` interface. At the moment, these tasks are `KotlinCompile` and `KaptTask`. If you want Gradle to search for the major JDK version, replace the `<MAJOR_JDK_VERSION>` placeholder in your build script:

Kotlin

```
val service = project.extensions.getByType<JavaToolchainService>()
val customLauncher = service.launcherFor {
    languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>))
}
project.tasks.withType<UsesKotlinJavaToolchain>().configureEach {
    kotlinJavaToolchain.toolchain.use(customLauncher)
}
```

Groovy

```
JavaToolchainService service = project.getExtensions().getByType(JavaToolchainService.class)
Provider<JavaLauncher> customLauncher = service.launcherFor {
    it.languageVersion = JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)
}
tasks.withType(UsesKotlinJavaToolchain::class).configureEach { task ->
    task.kotlinJavaToolchain.toolchain.use(customLauncher)
}
```

Or you can specify the path to your local JDK and replace the placeholder `<LOCAL_JDK_VERSION>` with this JDK version:

```
tasks.withType<UsesKotlinJavaToolchain>().configureEach {
    kotlinJavaToolchain.jdk.use(
        "/path/to/local/jdk", // Put a path to your JDK
        JavaVersion.<LOCAL_JDK_VERSION> // For example, JavaVersion.17
    )
}
```

Associate compiler tasks

You can *associate* compilations by setting up such a relationship between them that one compilation uses the compiled outputs of the other. Associating compilations establishes `internal` visibility between them.

The Kotlin compiler associates some compilations by default, such as the `test` and `main` compilations of each target. If you need to express that one of your custom compilations is connected to another, create your own associated compilation.

To make the IDE support associated compilations for inferring visibility between source sets, add the following code to your `build.gradle(.kts)`:

Kotlin

```
val integrationTestCompilation = kotlin.target.compilations.create("integrationTest") {
    associateWith(kotlin.target.compilations.getByName("main"))
}
```

Groovy

```
integrationTestCompilation {
    kotlin.target.compilations.create("integrationTest") {
        associateWith(kotlin.target.compilations.getByName("main"))
    }
}
```

Here, the `integrationTest` compilation is associated with the `main` compilation that gives access to `internal` objects from functional tests.

Configure with Java Modules (JPMS) enabled

To make the Kotlin Gradle plugin work with Java Modules, add the following lines to your build script and replace `YOUR_MODULE_NAME` with a reference to your JPMS module, for example, `org.company.module`:

Kotlin

```
tasks.named("compileJava", JavaCompile::class.java) {
    // Provide compiled Kotlin classes to javac - needed for Java/Kotlin mixed sources to work
    val mainOutput: FileCollection = sourceSets["main"].output
    options.compilerArgumentProviders.add(CommandLineArgumentProvider {
        listOf("--patch-module", "YOUR_MODULE_NAME=${mainOutput.asPath}")
    })
}
```

Groovy

```
tasks.named("compileJava", JavaCompile.class) {
    // Provide compiled Kotlin classes to javac - needed for Java/Kotlin mixed sources to work
    FileCollection mainOutput = sourceSets["main"].output
    options.compilerArgumentProviders.add(new CommandLineArgumentProvider() {
        @Override
        Iterable<String> asArguments() {
            return ["--patch-module", "YOUR_MODULE_NAME=${mainOutput.asPath}"]
        }
    })
}
```

Put `module-info.java` into the `src/main/java` directory as usual.

For a module, a package name in Kotlin files should be equal to the package name from `module-info.java` to avoid a "package is empty or does not exist" build failure.

- Building modules for the Java Module System
- Building applications using the Java Module System
- What "module" means in Kotlin

Other details

Disable use of artifact in compilation task

In some rare scenarios, you can experience a build failure caused by a circular dependency error. For example, when you have multiple compilations where one compilation can see all internal declarations of another, and the generated artifact relies on the output of both compilation tasks:

```
FAILURE: Build failed with an exception.

What went wrong:
Circular dependency between the following tasks:
:lib:compileKotlinJvm
--- :lib:jvmJar
     \--- :lib:compileKotlinJvm (*)
(*) - details omitted (listed previously)
```

To fix this circular dependency error, we've added a Gradle property: `archivesTaskOutputAsFriendModule`. This property controls the use of artifact inputs in the compilation task and determines if a task dependency is created as a result.

By default, this property is set to `true` to track the task dependency. If you encounter a circular dependency error, you can disable the use of the artifact in the compilation task to remove the task dependency and avoid the circular dependency error.

To disable the use of the artifact in the compilation task, add the following to your `gradle.properties` file:

```
kotlin.build.archivesTaskOutputAsFriendModule=false
```

Lazy Kotlin/JVM task creation

Starting from Kotlin 1.8.20, the Kotlin Gradle plugin registers all tasks and doesn't configure them on a dry run.

Non-default location of compile tasks' destinationDirectory

If you override the Kotlin/JVM `KotlinJvmCompile` / `KotlinCompile` task's `destinationDirectory` location, update your build script. You need to explicitly add `sourceSets.main.kotlin.classesDirectories` to `sourceSets.main.outputs` in your JAR file:

```
tasks.jar(type: Jar) {
    from sourceSets.main.outputs
    from sourceSets.main.kotlin.classesDirectories
}
```

Targeting multiple platforms

Projects targeting multiple platforms, called multiplatform projects, require the `kotlin-multiplatform` plugin.

The `kotlin-multiplatform` plugin works with Gradle 7.6.3 or later.

Kotlin

```
plugins {
    kotlin("multiplatform") version "2.4.20"
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.multiplatform' version '2.4.20'
}
```

Learn more about Kotlin Multiplatform for different platforms and Kotlin Multiplatform for iOS and Android.

Targeting Android

It's recommended to use Android Studio for creating Android applications. Learn how to use the Android Gradle plugin.

Targeting the web

Kotlin, through Kotlin Multiplatform, offers two approaches for web development:

- JavaScript-based (using the Kotlin/JS compiler)
- WebAssembly-based (using the Kotlin/Wasm compiler)

Both approaches use the Kotlin Multiplatform plugin but support different use cases. The sections below explain how to configure each target in your Gradle build and when to use them.

Targeting JavaScript

Use Kotlin/JS if your goal is to:

- Share business logic with a JavaScript/TypeScript codebase
- Build non-shareable web apps with Kotlin

For more information, see Web development.

When targeting JavaScript, use the `kotlin-multiplatform` plugin:

Kotlin

```
plugins {
    kotlin("multiplatform") version "2.4.20"
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.multiplatform' version '2.4.20'
}
```

Configure the JavaScript target by specifying whether it should run in the browser or the Node.js environment:

```
kotlin {
    js().browser {  // or js().nodejs
        /* ... */
    }
}
```

See further details about the Gradle configuration for JavaScript and learn more about setting up a Kotlin/JS project.

Targeting WebAssembly

Use Kotlin/Wasm if you want to share both logic and UI across multiple platforms. For more information, see Web development.

As with JavaScript, use the `kotlin-multiplatform` plugin when targeting WebAssembly (Wasm):

Kotlin

```
plugins {
    kotlin("multiplatform") version "2.4.20"
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.multiplatform' version '2.4.20'
}
```

Depending on your requirements, you can target:

- `wasmJs`: for running in browsers or Node.js
- `wasmWasi`: for running in Wasm environments supporting WASI (WebAssembly System Interface), such as Wasmtime, WasmEdge, and so on.

Configure the `wasmJs` target for web browsers or Node.js:

```
kotlin {
    wasmJs {
        browser { // or nodejs
            /* ... */
        }
    }
}
```

For WASI environments, configure the `wasmWasi` target with Node.js or Wasmtime:

```
kotlin {
    wasmWasi {
        nodejs { // or wasmtime
            /* ... */
        }
    }
}
```

See further details about the Gradle configuration for Wasm.

Kotlin and Java sources for the web target

The KGP only works for Kotlin files, so it is recommended that you keep Kotlin and Java files separate (if the project contains Java files). If you don't store them separately, specify the source folder in the `sourceSets{}` block:

Kotlin

```
kotlin {
    sourceSets["main"].apply {
        kotlin.srcDir("src/main/myKotlin")
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        main.kotlin.srcDirs += 'src/main/myKotlin'
    }
}
```

Triggering configuration actions with the KotlinBasePlugin interface

To trigger some configuration action whenever any Kotlin Gradle plugin (JVM, JS, Multiplatform, Native, and others) is applied, use the `KotlinBasePlugin` interface that all Kotlin plugins inherit from:

Kotlin

```kotlin
import org.jetbrains.kotlin.gradle.plugin.KotlinBasePlugin

// ...

project.plugins.withType<KotlinBasePlugin>() {
    // Configure your action here
}
```

Groovy

```groovy
import org.jetbrains.kotlin.gradle.plugin.KotlinBasePlugin

// ...

project.plugins.withType(KotlinBasePlugin.class) {
    // Configure your action here
}
```

Configure dependencies

To add a dependency on a library, set the dependency of the required type (for example, `implementation`) in the `dependencies{}` block of the source sets DSL.

Kotlin

```kotlin
kotlin {
    sourceSets {
        commonMain.dependencies {
            implementation("com.example:my-library:1.0")
        }
    }
}
```

Groovy

```groovy
kotlin {
    sourceSets {
        commonMain {
            dependencies {
                implementation 'com.example:my-library:1.0'
            }
        }
    }
}
```

Experimental

Configure dependencies at the top level

You can configure common dependencies in multiplatform projects using a top-level `dependencies {}` block. Dependencies declared here behave as if they were added to the `commonMain` or `commonTest` source sets.

To use the top-level `dependencies {}` block, opt in by adding the `@OptIn(ExperimentalKotlinGradlePluginApi::class)` annotation before the block:

Kotlin

```
kotlin {
    @OptIn(ExperimentalKotlinGradlePluginApi::class)
    dependencies {
        implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
    }
}
```

Groovy

```
kotlin {
    dependencies {
        implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
    }
}
```

Add platform-specific dependencies inside the `sourceSets {}` block of the corresponding target.

You can share your feedback on this feature in YouTrack.

Dependency types

Choose the dependency type based on your requirements.

Type	Description	When to use
`api`	Used both during compilation and at runtime and is exported to library consumers.	If any type from a dependency is used in the public API of the current module, use an `api` dependency.
`implementation`	Used during compilation and at runtime for the current module, but is not exposed for compilation of other modules depending on the one with the `implementation` dependency.	Use for dependencies needed for the internal logic of a module. If a module is an endpoint application which is not published, use `implementation` dependencies instead of `api` dependencies.
`compileOnly`	Used for compilation of the current module and is not available at runtime nor during compilation of other modules.	Use for APIs which have a third-party implementation available at runtime.

Type	Description	When to use
`runtimeOnly`	Available at runtime but is not visible during compilation of any module.	

Dependency on the standard library

A dependency on the standard library (`stdlib`) is added automatically to each source set. The version of the standard library used is the same as the version of the Kotlin Gradle plugin.

For platform-specific source sets, the corresponding platform-specific variant of the library is used, while a common standard library is added to the rest. The Kotlin Gradle plugin selects the appropriate JVM standard library depending on the `compilerOptions.jvmTarget` compiler option of your Gradle build script.

If you declare a standard library dependency explicitly (for example, if you need a different version), the Kotlin Gradle plugin won't override it or add a second standard library.

If you don't need a standard library at all, you can add the following Gradle property to your `gradle.properties` file:

```
kotlin.stdlib.default.dependency=false
```

Versions alignment of transitive dependencies

From Kotlin standard library version 1.9.20, Gradle uses metadata included in the standard library to automatically align transitive `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` dependencies.

If you add a dependency for any Kotlin standard library version between 1.8.0 – 1.9.10, for example: `implementation("org.jetbrains.kotlin:kotlin-stdlib:1.8.0")` , then the Kotlin Gradle Plugin uses this Kotlin version for transitive `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` dependencies. This avoids class duplication from different standard library versions. Learn more about merging `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` into `kotlin-stdlib` . You can disable this behavior with the `kotlin.stdlib.jdk.variants.version.alignment` Gradle property in your `gradle.properties` file:

```
kotlin.stdlib.jdk.variants.version.alignment=false
```

Other ways to align versions

- If you have issues with version alignment, you can align all versions via the Kotlin BOM. Declare a platform dependency on `kotlin-bom` in your build script:

  Kotlin

  ```
  implementation(platform("org.jetbrains.kotlin:kotlin-bom:2.4.20"))
  ```

  Groovy

  ```
  implementation platform('org.jetbrains.kotlin:kotlin-bom:2.4.20')
  ```

-

If you don't add a dependency for a standard library version, but you have two different dependencies that transitively bring different old versions of the Kotlin standard library, then you can explicitly require `2.4.20` versions of these transitive libraries:

Kotlin

```
dependencies {
    constraints {
        add("implementation", "org.jetbrains.kotlin:kotlin-stdlib-jdk7") {
            version {
                require("2.4.20")
            }
        }
        add("implementation", "org.jetbrains.kotlin:kotlin-stdlib-jdk8") {
            version {
                require("2.4.20")
            }
        }
    }
}
```

Groovy

```
dependencies {
    constraints {
        add("implementation", "org.jetbrains.kotlin:kotlin-stdlib-jdk7") {
            version {
                require("2.4.20")
            }
        }
        add("implementation", "org.jetbrains.kotlin:kotlin-stdlib-jdk8") {
            version {
                require("2.4.20")
            }
        }
    }
}
```

- If you add a dependency for Kotlin standard library version `2.4.20`: `implementation("org.jetbrains.kotlin:kotlin-stdlib:2.4.20")`, and an old version (earlier than `1.8.0`) of the Kotlin Gradle plugin, update the Kotlin Gradle plugin to match the standard library version:

Kotlin

```
plugins {
    // replace `<...>` with the plugin name
    kotlin("<...>") version "2.4.20"
}
```

Groovy

```
plugins {
    // replace `<...>` with the plugin name
    id "org.jetbrains.kotlin.<...>" version "2.4.20"
}
```

- If you use versions prior to `1.8.0` of `kotlin-stdlib-jdk7` / `kotlin-stdlib-jdk8`, for example, `implementation("org.jetbrains.kotlin:kotlin-stdlib-jdk7:SOME_OLD_KOTLIN_VERSION")`, and a dependency that transitively brings `kotlin-stdlib:1.8+`, replace your `kotlin-stdlib-jdk<7/8>:SOME_OLD_KOTLIN_VERSION` with `kotlin-stdlib-jdk*:2.4.20` or exclude the transitive `kotlin-stdlib:1.8+` from the library that brings it:

Kotlin

```
dependencies {
    implementation("com.example:lib:1.0") {
        exclude(group = "org.jetbrains.kotlin", module = "kotlin-stdlib")
    }
}
```

Groovy

```
dependencies {
    implementation("com.example:lib:1.0") {
        exclude group: "org.jetbrains.kotlin", module: "kotlin-stdlib"
    }
}
```

Set dependencies on test libraries

The `kotlin.test` API is available for testing Kotlin projects on all supported platforms. Add the `kotlin-test` dependency to the `commonTest` source set, so that the Gradle plugin can infer the corresponding test dependencies for each test source set.

Kotlin/Native targets do not require additional test dependencies, and the `kotlin.test` API implementations are built-in.

Kotlin

```
kotlin {
    sourceSets {
        commonTest.dependencies {
            implementation(kotlin("test")) // This brings all the platform dependencies automatically
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        commonTest {
            dependencies {
                implementation kotlin("test") // This brings all the platform dependencies
automatically
            }
        }
    }
}
```

You can use shorthand for a dependency on a Kotlin module, for example, kotlin("test") for "org.jetbrains.kotlin:kotlin-test".

You can use the `kotlin-test` dependency in any shared or platform-specific source set as well.

JVM variants of kotlin-test

For Kotlin/JVM, Gradle uses JUnit 4 by default. Therefore, the `kotlin("test")` dependency resolves to the variant for JUnit 4, namely `kotlin-test-junit`.

You can choose JUnit 5 or TestNG by calling `useJUnitPlatform()` or `useTestNG()` in the test task of your build script. The following example is for a Kotlin Multiplatform project:

Kotlin

```
kotlin {
    jvm {
        testRuns["test"].executionTask.configure {
            useJUnitPlatform()
        }
    }
    sourceSets {
        commonTest.dependencies {
            implementation(kotlin("test"))
        }
    }
}
```

Groovy

```
kotlin {
    jvm {
        testRuns["test"].executionTask.configure {
            useJUnitPlatform()
        }
    }
    sourceSets {
        commonTest {
            dependencies {
                implementation kotlin("test")
            }
        }
    }
}
```

The following example is for a JVM project:

Kotlin

```
dependencies {
    testImplementation(kotlin("test"))
}

tasks {
    test {
        useTestNG()
    }
}
```

Groovy

```
dependencies {
    testImplementation 'org.jetbrains.kotlin:kotlin-test'
}

test {
    useTestNG()
}
```

Learn how to test code using JUnit on the JVM.

Automatic JVM variant resolution can sometimes cause problems for your configuration. In that case, you can specify the necessary framework explicitly and disable the automatic resolution by adding this line to the project `gradle.properties` file:

```
kotlin.test.infer.jvm.variant=false
```

If you have used a variant of `kotlin("test")` in your build script explicitly and your project build stopped working with a compatibility conflict, see this issue in the Compatibility guide.

Set a dependency on a kotlinx library

If you use a multiplatform library and need to depend on the shared code, set the dependency only once in the shared source set. Use the library's base artifact name, such as `kotlinx-coroutines-core` or `ktor-client-core`:

Kotlin

```
kotlin {
    sourceSets {
        commonMain.dependencies {
            implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        commonMain {
            dependencies {
                implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
            }
        }
    }
}
```

If you need a kotlinx library for a platform-specific dependency, you can still use the library's base artifact name in the corresponding platform source set:

Kotlin

```
kotlin {
    sourceSets {
        jvmMain.dependencies {
            implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        jvmMain {
            dependencies {
                implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
            }
        }
    }
}
```

Declare repositories

You can declare a publicly-available repository to use its open source dependencies. In the `repositories{}` block, set the name of the repository:

Kotlin

```
repositories {
    mavenCentral()
}
```

Groovy

```
repositories {
    mavenCentral()
}
```

Popular repositories are Maven Central and Google's Maven repository.

If you also work with Maven projects, we recommend avoiding adding `mavenLocal()` as a repository because you may experience problems when switching between Gradle and Maven projects. If you must add the `mavenLocal()` repository, add it as the last repository in your `repositories{}` block. For more information, see The case for mavenLocal().

If you need to declare the same repositories in more than one subproject, declare the repositories centrally in the `dependencyResolutionManagement{}` block in your `settings.gradle(.kts)` file:

Kotlin

```
dependencyResolutionManagement {
    repositories {
        mavenCentral()
    }
}
```

Groovy

```
dependencyResolutionManagement {
    repositories {
        mavenCentral()
    }
}
```

Any declared repositories in subprojects override repositories declared centrally. For more information on how to control this behavior and what options are available, see Gradle's documentation.

Experimental

Register generated sources

Register generated sources to help IDEs, third-party plugins, and other tools distinguish between generated code and regular source files. This helps tools like IDEs highlight generated code differently in the UI and trigger generation tasks when importing the project. Use the `KotlinSourceSet` interface to register generated sources.

To register a directory that contains Kotlin files, use the `generatedKotlin` property with the `SourceDirectorySet` type in your `build.gradle.kts` file. For example:

```
val generatorTask = project.tasks.register("generator") {
    val outputDirectory = project.layout.projectDirectory.dir("src/main/kotlinGen")
    outputs.dir(outputDirectory)
    doLast {
        outputDirectory.file("generated.kt").asFile.writeText(
            // language=kotlin
            """
            fun printHello() {
                println("hello")
            }
            """.trimIndent()
        )
    }
}

kotlin.sourceSets.getByName("main").generatedKotlin.srcDir(generatorTask)
```

This example creates a new task `generator` with an output directory of `"src/main/kotlinGen"`. When the task runs, the `doLast {}` task action creates a `generated.kt` file in the output directory. Finally, the example registers the task's output as a generated source.

If you're developing a Gradle plugin, you can use the `allKotlinSources` property to access all sources registered in the `KotlinSourceSet.kotlin` and `KotlinSourceSet.generatedKotlin` properties.

Gradle best practices

Gradle is a build system used by many Kotlin projects to automate and manage the build process.

Getting the best out of Gradle is essential to help you spend less time managing and waiting for builds, and more time coding. Here we provide a set of best practices split into two key areas: **organizing** and **optimizing** your projects.

Organize

This section focuses on structuring your Gradle projects to improve clarity, maintainability, and scalability.

Use Kotlin DSL

Use Kotlin DSL instead of the traditional Groovy DSL. You avoid learning another language and gain the benefits of strict typing. Strict typing lets IDEs provide better support for refactoring and auto-completion, making development more efficient.

Find more information in Gradle's Kotlin DSL primer.

Read Gradle's blog about Kotlin DSL becoming the default for Gradle builds.

Use a version catalog

Use a version catalog in a `libs.versions.toml` file to centralize dependency management. This enables you to define and reuse versions, libraries, and plugins consistently across projects.

```
[versions]
kotlinxCoroutines = "1.11.0"

[libraries]
kotlinxCoroutines = { module = "org.jetbrains.kotlinx:kotlinx-coroutines-core", version.ref =
"kotlinxCoroutines" }
```

With the following dependency added to your `build.gradle.kts` file:

```
dependencies {
    implementation(libs.kotlinxCoroutines)
}
```

Learn more in Gradle's documentation about Dependency management basics.

Use convention plugins

Use convention plugins to encapsulate and reuse common build logic across multiple build files. Moving a shared configuration into a plugin helps simplify and modularize your build scripts.

Although the initial setup may be time-consuming, it's easy to maintain and add new build logic once you complete it.

Learn more in Gradle's documentation about Convention plugins.

Optimize

This section provides strategies to enhance the performance and efficiency of your Gradle builds.

Use local build cache

Use a local build cache to save time by reusing outputs produced by other builds. The build cache can retrieve outputs from any earlier build that you have already created.

Learn more in Gradle's documentation about their Build cache.

Use configuration cache

> The configuration cache doesn't support all core Gradle plugins yet. For the latest information, see Gradle's table of supported plugins.

Use the configuration cache to significantly improve build performance by caching the result of the configuration phase and reusing it for subsequent builds. If Gradle detects no changes in the build configuration or related dependencies, it skips the configuration phase.

The configuration cache also enables parallel execution of independent tasks within a single project, which can further improve build performance. Additionally, it implicitly enables the `org.gradle.parallel` property, allowing tasks across different projects to execute in parallel.

Learn more about the configuration cache in Gradle's documentation.

Improve build times for multiple targets

When your multiplatform project includes multiple targets, tasks like `build` and `assemble` can compile the same code multiple times for each target, leading to longer compilation times.

If you're actively developing and testing a specific platform, run the corresponding `linkDebug*` task instead.

For more information, see Tips for improving compilation time.

Migrate from kapt to KSP

If you're using a library that relies on the kapt compiler plugin, check whether you can switch to using the Kotlin Symbol Processing (KSP) API instead. The KSP API improves build performance by reducing annotation processing time. KSP is faster and more efficient than kapt, as it processes source code directly without generating intermediary Java stubs.

For guidance on the migration steps, see the migration guide.

Use modularization

> Modularization only benefits projects of moderate to large size. It doesn't provide advantages for projects based on a microservices architecture.

Use a modularized project structure to increase build speed and enable easier parallel development. Structure your project into one root project and one or more subprojects. If changes only affect one of the subprojects, Gradle rebuilds only that specific subproject.

```
.
└── root-project/
    ├── settings.gradle.kts
    ├── app subproject/
    │   └── build.gradle.kts
    └── lib subproject/
        └── build.gradle.kts
```

Learn more in Gradle's documentation about Structuring projects with Gradle.

Set up CI/CD

Set up a CI/CD process to significantly reduce build time by using incremental builds and caching dependencies. Add persistent storage or use a remote build cache to see these benefits. This process doesn't have to be time-consuming, as some providers, like GitHub, offer this service almost out of the box.

Explore Gradle's community cookbook on Using Gradle with Continuous Integration systems.

Use remote build cache

Like the local build cache, the remote build cache helps you save time by reusing outputs from other builds. It can retrieve task outputs from any earlier build that anyone has already run, not just the last one.

The remote build cache uses a cache server to share task outputs across builds. For example, in a development environment with a CI/CD server, all builds on the server populate the remote cache. When you check out the main branch to start a new feature, you can immediately access incremental builds.

Keep in mind that a slow internet connection might make transferring cached results slower than running tasks locally.

Learn more in Gradle's documentation about their Build cache.

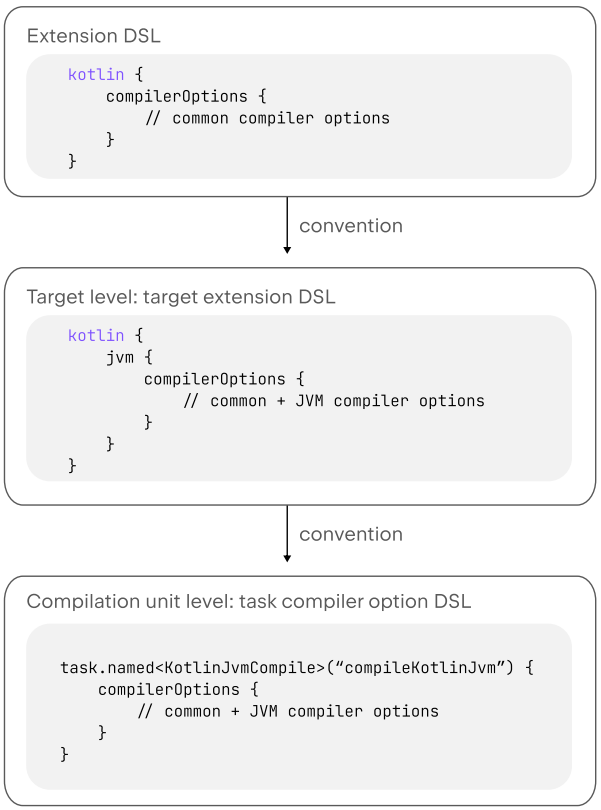
Compiler options in the Kotlin Gradle plugin

Each release of Kotlin includes compilers for the supported targets: JVM, JavaScript, and native binaries for supported platforms.

These compilers are used by:

- The IDE, when you click the **Compile** or **Run** button for your Kotlin project.
- Gradle, when you call `gradle build` in a console or in the IDE.
- Maven, when you call `mvn compile` or `mvn test-compile` in a console or in the IDE.

You can also run Kotlin compilers manually from the command line as described in the Working with command-line compiler tutorial.



How to define options

Kotlin compilers have a number of options for tailoring the compiling process.

The Gradle DSL allows comprehensive configuration of compiler options. It is available for Kotlin Multiplatform and JVM/Android projects.

With the Gradle DSL, you can configure compiler options within the build script at three levels:

- Extension level, in the `kotlin {}` block for all targets and shared source sets.
- Target level, in the block for a specific target.
- Compilation unit level, usually in a specific compilation task.

Kotlin compiler options levels

The settings at a higher level are used as a convention (default) for a lower level:

- Compiler options set at the extension level are the default for target-level options, including shared source sets like `commonMain`, `nativeMain`, and `commonTest`.
- Compiler options set at the target level are the default for options at the compilation unit (task) level, like `compileKotlinJvm` and `compileTestKotlinJvm` tasks.

In turn, configurations made at a lower level override related settings at a higher level:

- Task-level compiler options override related configurations at the target or the extension level.
- Target-level compiler options override related configurations at the extension level.

To find out which level of compiler arguments is applied to the compilation, use the `DEBUG` level of Gradle logging. For JVM and JS/WASM tasks, search for the `"Kotlin compiler args:"` string within the logs; for Native tasks, search for the `"Arguments ="` string.

> If you're a third-party plugin author, it's best to apply your configuration on the project level to avoid overriding issues. You can use the new Kotlin plugin DSL extension types for this. It's recommended that you document this configuration on your side explicitly.

Extension level

You can configure common compiler options for all the targets and shared source sets in the `compilerOptions {}` block at the top level:

```
kotlin {
    compilerOptions {
        optIn.add("kotlin.RequiresOptIn")
    }
}
```

Target level

You can configure compiler options for the JVM/Android target in the `compilerOptions {}` block inside the `target {}` block:

```
kotlin {
    target {
        compilerOptions {
            optIn.add("kotlin.RequiresOptIn")
        }
    }
}
```

In Kotlin Multiplatform projects, you can configure compiler options inside the specific target. For example, `jvm { compilerOptions {}}`. For more information, see Multiplatform Gradle DSL reference.

Compilation unit level

You can configure compiler options for a specific compilation unit or task in a `compilerOptions {}` block inside the task configuration:

```
tasks.named<KotlinJvmCompile>("compileKotlin"){
    compilerOptions {
        optIn.add("kotlin.RequiresOptIn")
    }
}
```

You can also access and configure compiler options at a compilation unit level via `KotlinCompilation`:

```
kotlin {
    target {
        val main by compilations.getting {
            compileTaskProvider.configure {
                compilerOptions {
                    optIn.add("kotlin.RequiresOptIn")
                }
            }
        }
    }
}
```

If you want to configure a plugin of a target different from JVM/Android and Kotlin Multiplatform, use the `compilerOptions {}` property of the corresponding Kotlin compilation task. The following examples show how to set this configuration up in both Kotlin and Groovy DSLs:

Kotlin

```
tasks.named("compileKotlin", org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask::class.java) {
    compilerOptions {
        apiVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_2_0)
    }
}
```

Groovy

```
tasks.named('compileKotlin', org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class) {
    compilerOptions {
        apiVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_2_0)
    }
}
```

Migrate from `kotlinOptions {}` to `compilerOptions {}`

Before Kotlin 2.2.0, you could configure compiler options using the `kotlinOptions {}` block. Since the `kotlinOptions {}` block is deprecated from Kotlin 2.0.0, this section provides guidance and recommendations for migrating your build scripts to use the `compilerOptions {}` block instead:

- Centralize compiler options and use types
- Migrate away from `android.kotlinOptions`
- Migrate `freeCompilerArgs`

Centralize compiler options and use types

Whenever possible, configure compiler options at the extension level, and override them for specific tasks at the compilation unit level.

You can't use raw strings in the `compilerOptions {}` block, so convert them to typed values. For example, if you have:

Kotlin

```
plugins {
    kotlin("jvm") version "2.4.20"
}

tasks.withType<KotlinCompile>().configureEach {
    kotlinOptions {
        jvmTarget = "17"
        languageVersion = "2.4"
        apiVersion = "2.4"
    }
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.jvm' version '2.4.20'
}

tasks.withType(KotlinCompile).configureEach {
    kotlinOptions {
        jvmTarget = '17'
        languageVersion = '2.4'
        apiVersion = '2.4'
    }
}
```

After migration, it should be:

Kotlin

```
import org.jetbrains.kotlin.gradle.dsl.JvmTarget
import org.jetbrains.kotlin.gradle.dsl.KotlinVersion

plugins {
    kotlin("jvm") version "2.4.20"
}

kotlin {
    // Extension level
    compilerOptions {
        jvmTarget = JvmTarget.fromTarget("17")
        languageVersion = KotlinVersion.fromVersion("2.4")
        apiVersion = KotlinVersion.fromVersion("2.4")
    }
}

// Example of overriding at compilation unit level
tasks.named<KotlinJvmCompile>("compileKotlin"){
    compilerOptions {
        apiVersion = KotlinVersion.fromVersion("2.4")
    }
}
```

Groovy

```
import org.jetbrains.kotlin.gradle.dsl.JvmTarget
import org.jetbrains.kotlin.gradle.dsl.KotlinVersion

plugins {
    id 'org.jetbrains.kotlin.jvm' version '2.4.20'
}

kotlin {
  // Extension level
    compilerOptions {
        jvmTarget = JvmTarget.fromTarget("17")
        languageVersion = KotlinVersion.fromVersion("2.4")
        apiVersion = KotlinVersion.fromVersion("2.4")
    }
}

// Example of overriding at compilation unit level
tasks.named("compileKotlin", KotlinJvmCompile).configure {
    compilerOptions {
        apiVersion = KotlinVersion.fromVersion("2.4")
    }
}
```

Migrate away from `android.kotlinOptions`

If your build script previously used `android.kotlinOptions`, migrate to `kotlin.compilerOptions` instead. Either at the extension level or the target level.

For example, if you have an Android project:

Kotlin

```
plugins {
    id("com.android.application")
    kotlin("android")
}

android {
    kotlinOptions {
        jvmTarget = "17"
    }
}
```

Groovy

```
plugins {
    id 'com.android.application'
    id 'org.jetbrains.kotlin.android'
}

android {
    kotlinOptions {
        jvmTarget = '17'
    }
}
```

Update it to:

Kotlin

```
plugins {
    id("com.android.application")
    kotlin("android")
}

kotlin {
    compilerOptions {
        jvmTarget = JvmTarget.fromTarget("17")
    }
}
```

Groovy

```
plugins {
    id 'com.android.application'
    id 'org.jetbrains.kotlin.android'
}

kotlin {
    compilerOptions {
        jvmTarget = JvmTarget.fromTarget("17")
    }
}
```

And for example, if you have a Kotlin Multiplatform project with an Android target:

Kotlin

```
plugins {
    kotlin("multiplatform")
    id("com.android.application")
}

kotlin {
    androidTarget {
        compilations.all {
            kotlinOptions.jvmTarget = "17"
        }
    }
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.multiplatform'
    id 'com.android.application'
}

kotlin {
    androidTarget {
        compilations.all {
            kotlinOptions {
                jvmTarget = '17'
            }
        }
    }
}
```

Update it to:

Kotlin

```
plugins {
    kotlin("multiplatform")
    id("com.android.application")
}

kotlin {
    androidTarget {
        compilerOptions {
            jvmTarget = JvmTarget.fromTarget("17")
        }
    }
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.multiplatform'
    id 'com.android.application'
}

kotlin {
    androidTarget {
        compilerOptions {
            jvmTarget = JvmTarget.fromTarget("17")
        }
    }
}
```

Migrate `freeCompilerArgs`

- Replace all `+=` operations with `add()` or `addAll()` functions.
- If you use the `-opt-in` compiler option, check whether a specialized DSL already is available in the KGP API reference and use that instead.
- Migrate any use of the `-progressive` compiler option to use the dedicated DSL: `progressiveMode.set(true)`.
- Migrate any use of the `-Xjvm-default` compiler option to use the dedicated DSL: `jvmDefault.set()`. Use the following mapping for the options:

Before	After
`-Xjvm-default=all-compatibility`	`jvmDefault.set(JvmDefaultMode.ENABLE)`
`-Xjvm-default=all`	`jvmDefault.set(JvmDefaultMode.NO_COMPATIBILITY)`
`-Xjvm-default=disable`	`jvmDefault.set(JvmDefaultMode.DISABLE)`

For example, if you have:

Kotlin

```
kotlinOptions {
    freeCompilerArgs += "-opt-in=kotlin.RequiresOptIn"
    freeCompilerArgs += listOf("-Xcontext-receivers", "-Xinline-classes", "-progressive", "-Xjvm-default=all")
}
```

Groovy

```
kotlinOptions {
    freeCompilerArgs += "-opt-in=kotlin.RequiresOptIn"
    freeCompilerArgs += ["-Xcontext-receivers", "-Xinline-classes", "-progressive", "-Xjvm-
default=all"]
}
```

Migrate to:

Kotlin

```
kotlin {
    compilerOptions {
        optIn.add("kotlin.RequiresOptIn")
        freeCompilerArgs.addAll(listOf("-Xcontext-receivers", "-Xinline-classes"))
        progressiveMode.set(true)
        jvmDefault.set(JvmDefaultMode.NO_COMPATIBILITY)
    }
}
```

Groovy

```
kotlin {
    compilerOptions {
        optIn.add("kotlin.RequiresOptIn")
        freeCompilerArgs.addAll(["-Xcontext-receivers", "-Xinline-classes"])
        progressiveMode.set(true)
        jvmDefault.set(JvmDefaultMode.NO_COMPATIBILITY)
    }
}
```

Target the JVM

As explained before, you can define compiler options for your JVM/Android projects at the extension, target, and compilation unit levels (tasks).

Default JVM compilation tasks are called `compileKotlin` for production code and `compileTestKotlin` for test code. The tasks for custom source sets are named according to their `compile<Name>Kotlin` patterns.

You can see the list of Android compilation tasks by running the `gradlew tasks --all` command in the terminal and searching for `compile*Kotlin` task names in the `Other tasks` group.

Some important details to be aware of:

- `kotlin.compilerOptions` configures every Kotlin compilation task in the project.
- You can override the configuration applied by `kotlin.compilerOptions` DSL using the `tasks.named<KotlinJvmCompile>("compileKotlin") { }` (or `tasks.withType<KotlinJvmCompile>().configureEach { }`) approach.

Target JavaScript

JavaScript compilation tasks are called `compileKotlinJs` for production code, `compileTestKotlinJs` for test code, and `compile<Name>KotlinJs` for custom source sets.

To configure a single task, use its name:

Kotlin

```kotlin
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask
// ...

val compileKotlin: KotlinCompilationTask<*> by tasks

compileKotlin.compilerOptions.suppressWarnings.set(true)
```

Groovy

```groovy
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask
// ...

tasks.named('compileKotlin', KotlinCompilationTask) {
    compilerOptions {
        suppressWarnings = true
    }
}
```

Note that with the Gradle Kotlin DSL, you should get the task from the project's `tasks` first.

Use the `Kotlin2JsCompile` and `KotlinCompileCommon` types for JS and common targets, respectively.

You can see the list of JavaScript compilation tasks by running the `gradlew tasks --all` command in the terminal and searching for `compile*KotlinJS` task names in the `Other tasks` group.

All Kotlin compilation tasks

It is also possible to configure all the Kotlin compilation tasks in the project:

Kotlin

```kotlin
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask
// ...

tasks.named<KotlinCompilationTask<*>>("compileKotlin").configure {
    compilerOptions { /*...*/ }
}
```

Groovy

```
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask
// ...

tasks.named('compileKotlin', KotlinCompilationTask) {
    compilerOptions { /*...*/ }
}
```

All compiler options

Here is a complete list of options for the Gradle compiler:

Common attributes

Name	Description	Possible values	Default value
`optIn`	A property for configuring a list of opt-in compiler arguments	`listOf( /* opt-ins */ )`	`emptyList()`
`progressiveMode`	Enables the progressive compiler mode	`true` , `false`	`false`
`extraWarnings`	Enables additional declaration, expression, and type compiler checks that emit warnings if true	`true` , `false`	`false`

Attributes specific to JVM

Name	Description	Possible values	Default value
`javaParameters`	Generate metadata for Java 1.8 reflection on method parameters		false
`jvmTarget`	Target version of the generated JVM bytecode	"1.8", "9", "10", ..., "25", 26". Also, see Types for compiler options	"1.8"
`noJdk`	Don't automatically include the Java runtime into the classpath		false

Name	Description	Possible values	Default value
`jvmTargetValidationMode`	• Validation of the JVM target compatibility between Kotlin and Java • A property for tasks of the `KotlinCompile` type.	`WARNING`, `ERROR`, `IGNORE`	`ERROR`
`jvmDefault`	Control how functions declared in interfaces are compiled to default methods on the JVM	`ENABLE`, `NO_COMPATIBILITY`, `DISABLE`	`ENABLE`

Attributes common to JVM and JavaScript

Name	Description	Possible values	Default value
`allWarningsAsErrors`	Report an error if there are any warnings		false
`suppressWarnings`	Don't generate warnings		false
`verbose`	Enable verbose logging output. Works only when the Gradle debug log level enabled		false
`freeCompilerArgs`	A list of additional compiler arguments. You can use experimental `-X` arguments here too. See an example		[]
`apiVersion`	Control which Kotlin APIs your code can use. For more information, see `-api-version`.	"2.0", "2.1", "2.2", "2.3", "2.4", "2.5" (EXPERIMENTAL)	
`languageVersion`	Control which Kotlin language features and syntax are available during compilation. For more information, see `-language-version`.	"2.0", "2.1", "2.2", "2.3", "2.4", "2.5" (EXPERIMENTAL)	

We are going to deprecate the attribute `freeCompilerArgs` in future releases. If you miss some option in the Kotlin Gradle DSL, please, file an issue.

Example of additional arguments usage via freeCompilerArgs

Use the `freeCompilerArgs` attribute to supply additional (including experimental) compiler arguments. You can add a single argument to this attribute or a list of arguments:

Kotlin

```kotlin
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask
// ...

kotlin {
    compilerOptions {
        // Specifies the version of the Kotlin API and the JVM target
        apiVersion.set(KotlinVersion.KOTLIN_2_4)
        jvmTarget.set(JvmTarget.JVM_1_8)

        // Single experimental argument
        freeCompilerArgs.add("-Xexport-kdoc")

        // Single additional argument
        freeCompilerArgs.add("-Xno-param-assertions")

        // List of arguments
        freeCompilerArgs.addAll(
            listOf(
                "-Xno-receiver-assertions",
                "-Xno-call-assertions"
            )
        )
    }
}
```

Groovy

```groovy
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask
// ...

tasks.named('compileKotlin', KotlinCompilationTask) {
    compilerOptions {
        // Specifies the version of the Kotlin API and the JVM target
        apiVersion = KotlinVersion.KOTLIN_2_4
        jvmTarget = JvmTarget.JVM_1_8

        // Single experimental argument
        freeCompilerArgs.add("-Xexport-kdoc")

        // Single additional argument, can be a key-value pair
        freeCompilerArgs.add("-Xno-param-assertions")

        // List of arguments
        freeCompilerArgs.addAll(["-Xno-receiver-assertions", "-Xno-call-assertions"])
    }
}
```

The `freeCompilerArgs` attribute is available at the extension, target, and compilation unit (task) levels.

Example of setting languageVersion

To set a language version, use the following syntax:

Kotlin

```
kotlin {
    compilerOptions {
        languageVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_2_4)
    }
}
```

Groovy

```
tasks
    .withType(org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class)
    .configureEach {
        compilerOptions.languageVersion =
            org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_2_4
    }
```

Also, see Types for compiler options.

Attributes specific to JavaScript

Name	Description	Possible values	Default value
`friendModulesDisabled`	Disable internal declaration export		`false`
`main`	Specify whether the `main` function should be called upon execution	`JsMainFunctionExecutionMode.CALL`, `JsMainFunctionExecutionMode.NO_CALL`	`JsMainFunctionExecutionMode.CALL`
`moduleKind`	The kind of JS module generated by the compiler	`JsModuleKind.MODULE_AMD`, `JsModuleKind.MODULE_PLAIN`, `JsModuleKind.MODULE_ES`, `JsModuleKind.MODULE_COMMONJS`, `JsModuleKind.MODULE_UMD`	`null`
`sourceMap`	Generate source map		`false`
`sourceMapEmbedSources`	Embed source files into the source map	`JsSourceMapEmbedMode.SOURCE_MAP_SOURCE_CONTENT_INLINING`, `JsSourceMapEmbedMode.SOURCE_MAP_SOURCE_CONTENT_NEVER`, `JsSourceMapEmbedMode.SOURCE_MAP_SOURCE_CONTENT_ALWAYS`	`null`

Name	Description	Possible values	Default value
`sourceMapNamesPolicy`	Add variable and function names that you declared in Kotlin code into the source map. For more information on the behavior, see our compiler reference	`JsSourceMapNamesPolicy.SOURCE_MAP_NAMES_POLICY_FQ_NAMES`, `JsSourceMapNamesPolicy.SOURCE_MAP_NAMES_POLICY_SIMPLE_NAMES`, `JsSourceMapNamesPolicy.SOURCE_MAP_NAMES_POLICY_NO`	`null`
`sourceMapPrefix`	Add the specified prefix to paths in the source map		`null`
`target`	Generate JS files for specific ECMA version	`"es5"`, `"es2015"`	`"es5"`
`useEsClasses`	Let generated JavaScript code use ES2015 classes. Enabled by default in case of ES2015 target usage		`null`

Types for compiler options

Some of the `compilerOptions` use the new types instead of the `String` type:

Option	Type	Example
`jvmTarget`	`JvmTarget`	`compilerOptions.jvmTarget.set(JvmTarget.JVM_11)`
`apiVersion` and `languageVersion`	`KotlinVersion`	`compilerOptions.languageVersion.set(KotlinVersion.KOTLIN_2_4)`
`main`	`JsMainFunctionExecutionMode`	`compilerOptions.main.set(JsMainFunctionExecutionMode.NO_CALL)`
`moduleKind`	`JsModuleKind`	`compilerOptions.moduleKind.set(JsModuleKind.MODULE_ES)`
`sourceMapEmbedSources`	`JsSourceMapEmbedMode`	`compilerOptions.sourceMapEmbedSources.set(JsSourceMapEmbedMode.SOURCE_MAP_SOURCE_CONTENT_INLINING)`
`sourceMapNamesPolicy`	`JsSourceMapNamesPolicy`	`compilerOptions.sourceMapNamesPolicy.set(JsSourceMapNamesPolicy.SOURCE_MAP_NAMES_POLICY_FQ_NAMES)`

Compilation and caches in the Kotlin Gradle plugin

On this page, you can learn about the following topics:

- Incremental compilation
- Gradle build cache support
- Gradle configuration cache support
- The Kotlin daemon and how to use it with Gradle
- Rolling back to the previous compiler
- Defining Kotlin compiler execution strategy
- Kotlin compiler fallback strategy
- Trying the latest language version
- Build reports

Incremental compilation

The Kotlin Gradle plugin supports incremental compilation, which is enabled by default for Kotlin/JVM and Kotlin/JS projects. Incremental compilation tracks changes to files in the classpath between builds so that only the files affected by these changes are compiled. This approach works with Gradle's build cache and supports compilation avoidance.

For Kotlin/JVM, incremental compilation relies on classpath snapshots, which capture the API structure of modules to determine when recompilation is necessary. To optimize the overall pipeline, the Kotlin compiler uses two types of classpath snapshots:

- **Fine-grained snapshots:** include detailed information about class members, such as properties or functions. When member-level changes are detected, the Kotlin compiler recompiles only the classes that depend on the modified members. To maintain performance, the Kotlin Gradle plugin creates coarse-grained snapshots for `.jar` files in the Gradle cache.
- **Coarse-grained snapshots:** only contain the class ABI hash. When a part of ABI changes, the Kotlin compiler recompiles all classes that depend on the changed class. This is useful for classes that change infrequently, such as external libraries.

Kotlin/JS projects use a different incremental compilation approach based on history files.

There are several ways to disable incremental compilation:

- Set `kotlin.incremental=false` for Kotlin/JVM.
- Set `kotlin.incremental.js=false` for Kotlin/JS projects.

- Use `-Pkotlin.incremental=false` or `-Pkotlin.incremental.js=false` as a command line parameter.

  The parameter should be added to each subsequent build.

When you disable incremental compilation, incremental caches become invalid after the build. The first build is never incremental.

> Sometimes problems with incremental compilation become visible several rounds after the failure occurs. Use build reports to track the history of changes and compilations. This can help you to provide reproducible bug reports.

To learn more about how our current incremental compilation approach works and compares to the previous one, see our blog post.

Gradle build cache support

The Kotlin plugin uses the Gradle build cache, which stores the build outputs for reuse in future builds.

To disable caching for all Kotlin tasks, set the system property `kotlin.caching.enabled` to `false` (run the build with the argument `-Dkotlin.caching.enabled=false`).

Gradle configuration cache support

The Kotlin plugin uses the Gradle configuration cache, which speeds up the build process by reusing the results of the configuration phase for subsequent builds.

See the Gradle documentation to learn how to enable the configuration cache. After you enable this feature, the Kotlin Gradle plugin automatically starts using it.

The Kotlin daemon and how to use it with Gradle

The Kotlin daemon:

- Runs with the Gradle daemon to compile the project.
- Runs separately from the Gradle daemon when you compile the project with an IntelliJ IDEA built-in build system.

The Kotlin daemon starts at the Gradle execution stage when one of the Kotlin compile tasks starts to compile sources. The Kotlin daemon stops either with the Gradle daemon or after two idle hours with no Kotlin compilation.

The Kotlin daemon uses the same JDK that the Gradle daemon does.

Setting Kotlin daemon's JVM arguments

Each of the following ways to set arguments overrides the ones that came before it:

- Gradle daemon arguments inheritance
- `kotlin.daemon.jvm.options` system property
- `kotlin.daemon.jvmargs` property
- `kotlin` extension

- Specific task definition

Gradle daemon arguments inheritance

By default, the Kotlin daemon inherits a specific set of arguments from the Gradle daemon but overwrites them with any JVM arguments specified directly for the Kotlin daemon. For example, if you add the following JVM arguments in the `gradle.properties` file:

```
org.gradle.jvmargs=-Xmx1500m -Xms500m -XX:MaxMetaspaceSize=1g
```

These arguments are then added to the Kotlin daemon's JVM arguments:

```
-Xmx1500m -XX:ReservedCodeCacheSize=320m -XX:MaxMetaspaceSize=1g -XX:UseParallelGC -ea -
XX:+UseCodeCacheFlushing -XX:+HeapDumpOnOutOfMemoryError -Djava.awt.headless=true -
Djava.rmi.server.hostname=127.0.0.1 --add-exports=java.base/sun.nio.ch=ALL-UNNAMED
```

To learn more about the Kotlin daemon's default behavior with JVM arguments, see Kotlin daemon's behavior with JVM arguments.

kotlin.daemon.jvm.options system property

If the Gradle daemon's JVM arguments have the `kotlin.daemon.jvm.options` system property – use it in the `gradle.properties` file:

```
org.gradle.jvmargs=-Dkotlin.daemon.jvm.options=-Xmx1500m,Xms500m
```

When passing arguments, follow these rules:

- Use the minus sign `-` **only** before the arguments `Xmx`, `XX:MaxMetaspaceSize`, and `XX:ReservedCodeCacheSize`.
- Separate arguments with commas (`,`) *without* spaces. Arguments that come after a space will be used for the Gradle daemon, not for the Kotlin daemon.

Gradle ignores these properties if all the following conditions are satisfied:

- Gradle is using JDK 1.9 or higher.
- The version of Gradle is between 7.0 and 7.1.1 inclusively.
- Gradle is compiling Kotlin DSL scripts.
- The Kotlin daemon isn't running.

To overcome this, upgrade Gradle to the version 7.2 (or higher) or use the `kotlin.daemon.jvmargs` property – see the following section.

kotlin.daemon.jvmargs property

You can add the `kotlin.daemon.jvmargs` property in the `gradle.properties` file:

```
kotlin.daemon.jvmargs=-Xmx1500m -Xms500m
```

Note that if you don't specify the `ReservedCodeCacheSize` argument here or in Gradle's JVM arguments, the Kotlin Gradle plugin applies a default value of `320m`:

```
-Xmx1500m -XX:ReservedCodeCacheSize=320m -Xms500m
```

kotlin extension

You can specify arguments in the `kotlin` extension:

Kotlin

```
kotlin {
    kotlinDaemonJvmArgs = listOf("-Xmx486m", "-Xms256m", "-XX:+UseParallelGC")
}
```

Groovy

```
kotlin {
    kotlinDaemonJvmArgs = ["-Xmx486m", "-Xms256m", "-XX:+UseParallelGC"]
}
```

Specific task definition

You can specify arguments for a specific task:

Kotlin

```
tasks.withType<CompileUsingKotlinDaemon>().configureEach {
    kotlinDaemonJvmArguments.set(listOf("-Xmx486m", "-Xms256m", "-XX:+UseParallelGC"))
}
```

Groovy

```
tasks.withType(CompileUsingKotlinDaemon).configureEach { task →
    task.kotlinDaemonJvmArguments = ["-Xmx1g", "-Xms512m"]
}
```

In this case, a new Kotlin daemon instance can start on task execution. Learn more about Kotlin daemon's behavior with JVM arguments.

Kotlin daemon's behavior with JVM arguments

When configuring the Kotlin daemon's JVM arguments, note that:

- It is expected to have multiple instances of the Kotlin daemon running at the same time when different subprojects or tasks have different sets of JVM arguments.

- A new Kotlin daemon instance starts only when Gradle runs a related compilation task and existing Kotlin daemons do not have the same set of JVM arguments. Imagine that your project has a lot of subprojects. Most of them require some heap memory for a Kotlin daemon, but one module requires a lot (though it is rarely compiled). In this case, you should provide a different set of JVM arguments for such a module, so a Kotlin daemon with a larger heap size would start only for developers who touch this specific module.

  > If you are already running a Kotlin daemon that has enough heap size to handle the compilation request, even if other requested JVM arguments are different, this daemon will be reused instead of starting a new one.

If the following arguments aren't specified, the Kotlin daemon inherits them from the Gradle daemon:

- `-Xmx`
- `-XX:MaxMetaspaceSize`
- `-XX:ReservedCodeCacheSize`. If not specified or inherited, the default value is `320m`.

The Kotlin daemon has the following default JVM arguments:

- `-XX:UseParallelGC`. This argument is only applied if no other garbage collector is specified.
- `-ea`
- `-XX:+UseCodeCacheFlushing`
- `-Djava.awt.headless=true`
- `-D{java.servername.property}={localhostip}`
- `--add-exports=java.base/sun.nio.ch=ALL-UNNAMED`. This argument is only applied for JDK versions 16 or higher.

> The list of default JVM arguments for the Kotlin daemon may vary between versions. You can use a tool like VisualVM to check the actual settings of a running JVM process, like the Kotlin daemon.

Rolling back to the previous compiler

From Kotlin 2.0.0, the K2 compiler is used by default.

To use the previous compiler from Kotlin 2.0.0 onwards, either:

- In your `build.gradle.kts` file, set your language version to `1.9`.

  OR

- Use the following compiler option: `-language-version 1.9`.

To learn more about the benefits of the K2 compiler, see the K2 compiler migration guide.

Trying the latest language version

Starting with Kotlin 2.0.0, to try the latest language version, set the `kotlin.experimental.tryNext` property in your `gradle.properties` file. When you use this property, the Kotlin Gradle plugin increments the language version to one above the default value for your Kotlin version. For example, in Kotlin 2.0.0, the default language version is 2.0, so the property configures language version 2.1.

Alternatively, you can run the following command:

```
./gradlew assemble -Pkotlin.experimental.tryNext=true
```

In build reports, you can find the language version used to compile each task.

Build reports

Build reports contain the durations of different compilation phases and any reasons why compilation couldn't be incremental. Use build reports to investigate performance issues when the compilation time is too long or when it differs for the same project.

Kotlin build reports help you to investigate problems with build performance more efficiently than with Gradle build scans that have a single Gradle task as the unit of granularity.

There are two common cases that analyzing build reports for long-running compilations can help you resolve:

- The build wasn't incremental. Analyze the reasons and fix underlying problems.
- The build was incremental but took too much time. Try reorganizing source files — split big files, save separate classes in different files, refactor large classes, declare top-level functions in different files, and so on.

Build reports also show the Kotlin version used in the project. In addition, starting with Kotlin 1.9.0, you can see which compiler was used to compile the code in your Gradle build scans.

Learn how to read build reports and about how JetBrains uses build reports.

Enabling build reports

To enable build reports, declare where to save the build report output in `gradle.properties`:

```
kotlin.build.report.output=file
```

The following values and their combinations are available for the output:

Option	Description
`file`	Saves build reports in a human-readable format to a local file. By default, it's `${project_folder}/build/reports/kotlin-build/${project_name}-timestamp.txt`
`single_file`	Saves build reports in a format of an object to a specified local file.
`build_scan`	Saves build reports in the `custom values` section of the build scan. Note that the Gradle Enterprise plugin limits the number of custom values and their length. In big projects, some values could be lost.
`http`	Posts build reports using HTTP(S). The POST method sends metrics in JSON format. You can see the current version of the sent data in the Kotlin repository. You can find samples of HTTP endpoints in this blog post

Option	Description
`json`	Saves build reports in JSON format to a local file. By default, it's `${project_folder}/build/reports/kotlin-build/${project_name}-build-<date-time>-<index>.json`.

Here's a list of available options for `kotlin.build.report`:

```
# Required outputs. Any combination is allowed
kotlin.build.report.output=file,single_file,http,build_scan,json

# Mandatory if single_file output is used. Where to put reports
# Use instead of the deprecated `kotlin.internal.single.build.metrics.file` property
kotlin.build.report.single_file=my/directory/path/some_filename

# Optional. Output directory for file-based or JSON reports. Default: build/reports/kotlin-build/
kotlin.build.report.file.output_dir=kotlin-reports

# Optional. Label for marking your build report (for example, debug parameters)
kotlin.build.report.label=some_label
```

Options, applicable only to HTTP:

```
# Mandatory. Where to post HTTP(S)-based reports
kotlin.build.report.http.url=http://127.0.0.1:8080

# Optional. User and password if the HTTP endpoint requires authentication
kotlin.build.report.http.user=someUser
kotlin.build.report.http.password=somePassword

# Optional. Add a Git branch name of a build to a build report
kotlin.build.report.http.include_git_branch.name=true|false

# Optional. Add compiler arguments to a build report
# If a project contains many modules, its compiler arguments in the report can be very heavy and not that helpful
kotlin.build.report.include_compiler_arguments=true|false
```

Limit of custom values

To collect build scans' statistics, Kotlin build reports use Gradle's custom values. Both you and different Gradle plugins can write data to custom values. The number of custom values has a limit. See the current maximum custom value count in the Build scan plugin docs.

If you have a big project, a number of such custom values may be quite big. If this number exceeds the limit, you can see the following message in the logs:

```
Maximum number of custom values (1,000) exceeded
```

To reduce the number of custom values the Kotlin plugin produces, you can use the following property in `gradle.properties`:

```
kotlin.build.report.build_scan.custom_values_limit=500
```

Switching off collecting project and system properties

HTTP build statistic logs can contain some project and system properties. These properties can change builds' behavior, so it's useful to log them in build statistics. These properties can store sensitive data, for example, passwords or a project's full path.

You can disable collection of these statistics by adding the `kotlin.build.report.http.verbose_environment` property to your `gradle.properties`.

JetBrains doesn't collect these statistics. You choose a place where to store your reports.

- Compiler execution strategy

Experimental

Binary compatibility validation in the Kotlin Gradle plugin

Binary compatibility validation helps library authors ensure that users don't break their code when upgrading to newer versions. It's important not only for delivering a smooth upgrade experience, but also for building long-term trust with users and encouraging continued adoption of the library.

Binary compatibility means that the compiled bytecode of two versions of a library can run interchangeably without needing recompilation.

The Kotlin Gradle plugin includes support for binary compatibility validation. The plugin generates Application Binary Interface (ABI) dumps from the current code and compares them with previous dumps to highlight differences. You can review these changes to find any potentially binary-incompatible modifications and take action to address them.

How to enable

To enable binary compatibility validation, in your `build.gradle.kts` file, add an `abiValidation {}` block. If you have no custom configuration, you can use the `abiValidation()` function instead:

Kotlin

```
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation()
}
```

Groovy

```
kotlin {
    abiValidation()
}
```

The KGP creates the necessary Gradle tasks. If your project has multiple modules where you want to check for binary compatibility, configure each module separately.

Check for binary compatibility issues

To check for potentially binary incompatible issues after making changes to your code, run the `checkKotlinAbi` Gradle task in IntelliJ IDEA or use the following command in your project directory:

```
./gradlew checkKotlinAbi
```

The task compares ABI dumps and prints any detected differences as errors. Check the output carefully to see if you need to make changes to your code to preserve binary compatibility.

By default, when binary compatibility validation is enabled in your project and you run the `check` task, Gradle also runs the `checkKotlinAbi` task.

Update reference ABI dump

To update the reference ABI dump that Gradle uses to check your latest changes, run the `updateKotlinAbi` task in IntelliJ IDEA or use the following command in your project directory:

```
./gradlew updateKotlinAbi
```

Only update the reference dump when you're confident your changes maintain binary compatibility with the previous version.

Configure filters

You can define filters to control which classes, properties, and functions the ABI dump includes. Use the `filters {}` block to add exclusion and inclusion rules with `excluded {}` and `included {}` blocks respectively.

Gradle includes a declaration in the ABI dump only if it doesn't match any exclusion rule. When inclusion rules are defined, the declaration must either match one of them or have at least one member that does.

A rule can be based on:

- The fully qualified name of a class, property, or function (`byNames`).
- The name of an annotation that has BINARY or RUNTIME retention (`annotatedWith`).

You can use wildcards `**`, `*`, and `?` in your rules for names:

- `**` matches zero or more characters, including periods.
- `*` matches zero or more characters excluding periods. Use this to specify a single class name.
- `?` matches exactly one character.

For example:

Kotlin

```
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation {
        filters {
            excluded {
                byNames.add("**.InternalUtils")
                annotatedWith.add("com.example.annotations.InternalApi")
            }

            included {
                byNames.add("com.example.api.**")
                annotatedWith.add("com.example.annotations.PublicApi")
            }
        }
    }
}
```

Groovy

```
kotlin {
    abiValidation {
        filters {
            excluded {
                byNames.add("**.InternalUtils")
                annotatedWith.add("com.example.annotations.InternalApi")
            }

            included {
                byNames.add("com.example.api.**")
                annotatedWith.add("com.example.annotations.PublicApi")
            }
        }
    }
}
```

This example:

- Excludes:
  - The `InternalUtils` class.
  - Declarations annotated with `@InternalApi`.
- Includes:

- Everything in the `com.example.api` package.
- Declarations annotated with `@PublicApi`.

To learn more about filtering, see the Kotlin Gradle plugin API reference.

Prevent inferred changes for unsupported targets

In multiplatform projects, if your host system can't compile all targets, the Kotlin Gradle plugin tries to infer ABI changes from the available targets. This helps avoid false failures when you later switch to a host that supports more targets.

To disable this behavior, add the following to your `build.gradle.kts` file:

Kotlin

```
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation {
        keepLocallyUnsupportedTargets.set(false)
    }
}
```

Groovy

```
kotlin {
    abiValidation {
        keepLocallyUnsupportedTargets = false
    }
}
```

If a target is unsupported and inference is disabled, the `checkKotlinAbi` task fails because it can't generate a complete ABI dump. This behavior may be useful if you'd prefer the task to fail rather than risk missing a binary-incompatible change.

Include publications from the `maven-publish` plugin

By default, binary compatibility validation uses Kotlin compilation outputs to generate ABI dumps. For this reason, the generated ABI dumps might not reflect the final published artifacts. For example, when you use the `maven-publish` plugin, post-processing steps such as relocation can modify artifacts after compilation.

To make sure the ABI dumps accurately reflect the artifacts published by the `maven-publish` plugin, add the following to your `build.gradle.kts` file:

Kotlin

```
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation {
        binariesSource.set(MAVEN_PUBLICATIONS)
    }
}
```

Groovy

```
kotlin {
    abiValidation {
        binariesSource = MAVEN_PUBLICATIONS
    }
}
```

Because Kotlin/Android projects and multiplatform projects with an Android target don't publish JAR files, this feature doesn't apply to them.

Support for Gradle plugin variants

Gradle 7.0 introduced a new feature for Gradle plugin authors — plugins with variants. This feature makes it easier to add support for latest Gradle features while maintaining compatibility with older Gradle versions. Learn more about variant selection in Gradle.

With Gradle plugin variants, the Kotlin team can ship different Kotlin Gradle plugin (KGP) variants for different Gradle versions. The goal is to support the base Kotlin compilation in the `main` variant, which corresponds to the oldest supported versions of Gradle. Each variant will have implementations for Gradle features from a corresponding release. The latest variant will support the latest Gradle feature set. With this approach, it is possible to extend support for older Gradle versions with limited functionality.

Currently, there are the following variants of the Kotlin Gradle plugin:

Variant's name	Corresponding Gradle versions
`main`	7.6.0–7.6.3
`gradle80`	8.0–8.0.2
`gradle81`	8.1.1
`gradle82`	8.2.1–8.4
`gradle85`	8.5
`gradle86`	8.6-8.7

Variant's name	Corresponding Gradle versions
`gradle88`	8.8-8.10
`gradle811`	8.11-8.12
`gradle813`	8.13-8.14
`gradle96`	9.6-9.7

In future Kotlin releases, more variants will be added.

To check which variant your build uses, enable the `--info` log level and find a string in the output starting with `Using Kotlin Gradle plugin`, for example, `Using Kotlin Gradle plugin main variant`.

Troubleshooting

Here are workarounds for some known issues with variant selection in Gradle:

- ResolutionStrategy in pluginManagement is not working for plugins with multivariants
- Plugin variants are ignored when a plugin is added as the `buildSrc` common dependency

Gradle can't select a KGP variant in a custom configuration

This is an expected situation that Gradle can't select a KGP variant in a custom configuration. If you use a custom Gradle configuration:

Kotlin

```
configurations.register("customConfiguration") {
    // ...
}
```

Groovy

```
configurations.register("customConfiguration") {
    // ...
}
```

And want to add a dependency on the Kotlin Gradle plugin, for example:

Kotlin

```
dependencies {
```

```
    customConfiguration("org.jetbrains.kotlin:kotlin-gradle-plugin:2.4.20")
}
```

Groovy

```
dependencies {
    customConfiguration 'org.jetbrains.kotlin:kotlin-gradle-plugin:2.4.20'
}
```

You need to add the following attributes to your `customConfiguration`:

Kotlin

```
configurations {
    customConfiguration {
        attributes {
            attribute(
                Usage.USAGE_ATTRIBUTE,
                project.objects.named(Usage.class, Usage.JAVA_RUNTIME)
            )
            attribute(
                Category.CATEGORY_ATTRIBUTE,
                project.objects.named(Category.class, Category.LIBRARY)
            )
            // If you want to depend on a specific KGP variant:
            attribute(
                GradlePluginApiVersion.GRADLE_PLUGIN_API_VERSION_ATTRIBUTE,
                project.objects.named("7.0")
            )
        }
    }
}
```

Groovy

```
configurations {
    customConfiguration {
        attributes {
            attribute(
                Usage.USAGE_ATTRIBUTE,
                project.objects.named(Usage, Usage.JAVA_RUNTIME)
            )
            attribute(
                Category.CATEGORY_ATTRIBUTE,
                project.objects.named(Category, Category.LIBRARY)
            )
            // If you want to depend on a specific KGP variant:
            attribute(
                GradlePluginApiVersion.GRADLE_PLUGIN_API_VERSION_ATTRIBUTE,
                project.objects.named('7.0')
            )
        }
    }
}
```

Otherwise, you will receive an error similar to this:

```
> Could not resolve all files for configuration ':customConfiguration'.
      > Could not resolve org.jetbrains.kotlin:kotlin-gradle-plugin:1.7.0.
        Required by:
            project :
         > Cannot choose between the following variants of org.jetbrains.kotlin:kotlin-gradle-
plugin:1.7.0:
             - gradle70RuntimeElements
             - runtimeElements
           All of them match the consumer attributes:
             - Variant 'gradle70RuntimeElements' capability org.jetbrains.kotlin:kotlin-gradle-
plugin:1.7.0:
                 - Unmatched attributes:
```

What's next?

Learn more about Gradle basics and specifics.

Maven

Maven is a build system that helps manage Kotlin-only or mixed Kotlin-Java projects and automate your building process. It works with JVM-based projects and downloads required dependencies, compiles and packages your code. Learn more about its basics and specifics on the Maven website.

Here's a general workflow when working with a Kotlin Maven project:

1. Configure your Java or Kotlin project.
2. Declare repositories.
3. Set project dependencies.
4. Configure Kotlin compiler.
5. Package your application.

To get started, you can also follow our step-by-step tutorials:

- Configure a Java project to work with Kotlin
- Test your Java Maven project with Kotlin and JUnit

> You can check out our public sample project with both Maven and Gradle build files already set up for a mixed Kotlin/Java project.

What's next?

- **Improve your debugging experience** with the `power-assert` plugin.
- **Measure test coverage and generate reports** with the `kover-maven-plugin`.
- **Configure annotation processing** with the kapt plugin.
- **Generate documentation** with the Dokka documentation engine. It supports mixed-language projects and can generate output in multiple formats, including standard Javadoc.
- **Enable OSGi support** by adding the `kotlin-osgi-bundle`.

Configure a Maven project

When you introduce Kotlin to your existing Java Maven project or create a new Kotlin Maven project, you need to add the Kotlin Maven plugin that compiles Kotlin sources and modules.

Currently, only Maven v3 is supported.

Automatic configuration

You can simplify Maven configuration in both mixed Java-Kotlin projects and in pure Kotlin projects using the `<extensions>` option. This approach saves you time because you don't need to configure the Maven compiler plugin.

To apply the Kotlin Maven plugin with `<extensions>`, update your `pom.xml` build file as follows:

1. In the `<properties>` section, define the target versions of Kotlin and the JVM:

```
<properties>
    <maven.compiler.release>17</maven.compiler.release>
    <kotlin.version>2.4.20</kotlin.version>
</properties>
```

2. In the `<build><plugins>` section, add the Kotlin Maven plugin with the enabled `<extensions>` option:

```
<build>
    <plugins>
        <!-- Kotlin compiler plugin configuration -->
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>${kotlin.version}</version>
            <extensions>true</extensions> <!-- Enable the extension -->
        </plugin>
        <!-- No need to configure Maven compiler plugin with extensions -->
    </plugins>
</build>
```

The `<extensions>` option:

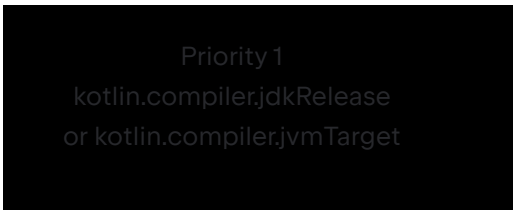
- Registers `src/main/kotlin` and `src/test/kotlin` directories as source roots if they already exist but are not specified in the plugin configuration.
- Adds the `kotlin-stdlib` dependency if it's not already defined in the project.
- Adds `compile`, `test-compile`, `kapt`, and `test-kapt` executions to your build, bound to their appropriate lifecycle phases. So you don't need to manually set up the `<executions>` section with `<id>` and `<goals>` for `kapt`, Kotlin's `compile`, and Java's `compile` executions to ensure they run in the correct order.
- Automatically aligns the JVM target version with the Java compiler version configured in the project.

If you have a mixed Java and Kotlin project, the configuration ensures that:

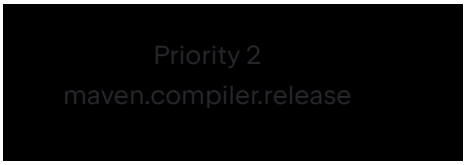
- Kotlin code is compiled first.
- Java code is compiled after Kotlin and can reference Kotlin classes.
- Default Maven behavior doesn't override the plugin order.

The extension configuration replaces the whole `<executions>` section. If you need to configure an execution, see an example in Compile Kotlin and Java sources.

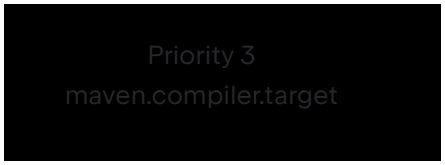
> If several build plugins overwrite the default lifecycle, and you have also enabled the `<extensions>` option, the last plugin in the `<build>` section has priority for lifecycle settings. All earlier changes to lifecycle settings are ignored.



Currently, the default version of the Maven compiler plugin used with `<extensions>` is **3.10.1**. You can set a different version separately:



```
<build>
    <plugins>
        <!-- Kotlin compiler plugin configuration -->
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>${kotlin.version}</version>
            <extensions>true</extensions>
        </plugin>
        <!-- Maven compiler plugin configuration for Java classes -->
        <plugin>
            <groupId>org.apache.maven.plugins</groupId>
            <artifactId>maven-compiler-plugin</artifactId>
            <version>3.15.0</version>
        </plugin>
    </plugins>
</build>
```



JVM target version

The `<extensions>` option ensures that the Kotlin and Maven compilers target the same bytecode version.

The Kotlin Maven plugin automatically resolves the JVM target version in the following order:

Kotlin compiler versions

The version set in `kotlin.compiler.jdkRelease` or `kotlin.compiler.jvmTarget` property takes priority if either is defined in the project.

Keep in mind that these Kotlin compiler options behave differently:

Kotlin compiler option	Controls bytecode version of the output	Limits API to specified JDK
`kotlin.compiler.jvmTarget`	Yes	No restrictions on JDK APIs in your code
`kotlin.compiler.jdkRelease`	Yes	Yes - only specific API version is allowed (equivalent to Java's `--release` compiler option)

Do not set different JDK options for `kotlin.compiler.jdkRelease` and `kotlin.compiler.jvmTarget` at the same time. Otherwise, you'll get an error.

Maven compiler versions

- If neither the `kotlin.compiler.jdkRelease` nor the `kotlin.compiler.jvmTarget` option is set, the plugin takes the `maven.compiler.release` version.

  The `maven.compiler.release` version can be defined either as a project property or within the `maven-compiler-plugin` configuration.

- If the Maven release version isn't set, the plugin takes the `maven.compiler.target` version.

  It can be defined either as a project property or within the `maven-compiler-plugin` configuration.

Keep in mind that `target` and `release` options of the Maven compiler behave differently:

Maven compiler option	Sets Kotlin's `jvmTarget`	Sets Kotlin's `jdkRelease`	Limits API to specified JDK
`maven.compiler.target`	Yes	No	No - the build's JDK classpath stays visible
`maven.compiler.release`	Yes	Yes	Yes - to the specific API version only

The `<extensions>` option only checks project-level properties and the global `maven-compiler-plugin` configuration. It doesn't check the configurations defined in the plugin's `<executions>` section.

Manual configuration

Without enabling `<extensions>` in the Kotlin Maven plugin, you need to configure the project manually to ensure that the source code compiles correctly.

You can set up your Maven project to compile a combination of Java and Kotlin sources or Kotlin-only sources.

Compile Kotlin and Java sources

To compile a project with both Kotlin and Java source files, ensure that the Kotlin compiler runs before the Java compiler.

The Java compiler can't see Kotlin declarations until they are compiled into `.class` files. If your Java code uses Kotlin classes, those classes must be compiled first to avoid `cannot find symbol` errors.

Maven determines plugin execution order based on two main factors:

- The order of plugin declarations in the `pom.xml` file.
- Built-in default executions, such as `default-compile` and `default-testCompile`, which always run before user-defined executions, regardless of their position in the `pom.xml` file.

To control the execution order:

- Declare `kotlin-maven-plugin` before `maven-compiler-plugin`.
- Disable the Java compiler plugin's default executions.
- Add custom executions to control compile phases explicitly.

You can use the special `none` phase in Maven to disable a default execution.

To apply the Kotlin Maven plugin, update your `pom.xml` build file as follows:

```
<build>
    <plugins>
        <!-- Kotlin compiler plugin configuration -->
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>${kotlin.version}</version>
            <executions>
                <execution>
                    <id>kotlin-compile</id>
                    <phase>compile</phase>
                    <goals>
                        <goal>compile</goal>
                    </goals>
                    <configuration>
                        <sourceDirs>
                            <sourceDir>${project.basedir}/src/main/kotlin</sourceDir>
                            <!-- Ensure Kotlin code can reference Java code -->
                            <sourceDir>${project.basedir}/src/main/java</sourceDir>
                        </sourceDirs>
                    </configuration>
                </execution>
                <execution>
                    <id>kotlin-test-compile</id>
                    <phase>test-compile</phase>
                    <goals>
                        <goal>test-compile</goal>
                    </goals>
                    <configuration>
                        <sourceDirs>
                            <sourceDir>${project.basedir}/src/test/kotlin</sourceDir>
                            <sourceDir>${project.basedir}/src/test/java</sourceDir>
                        </sourceDirs>
                    </configuration>
                </execution>
            </executions>
        </plugin>

        <!-- Maven compiler plugin configuration -->
        <plugin>
            <groupId>org.apache.maven.plugins</groupId>
            <artifactId>maven-compiler-plugin</artifactId>
            <version>3.15.0</version>
            <executions>
                <!-- Disable default executions -->
                <execution>
                    <id>default-compile</id>
                    <phase>none</phase>
                </execution>
                <execution>
                    <id>default-testCompile</id>
                    <phase>none</phase>
                </execution>

                <!-- Define custom executions -->
                <execution>
                    <id>java-compile</id>
                    <phase>compile</phase>
                    <goals>
                        <goal>compile</goal>
                    </goals>
                </execution>
                <execution>
```

```
                    <id>java-test-compile</id>
                    <phase>test-compile</phase>
                    <goals>
                        <goal>testCompile</goal>
                    </goals>
                </execution>
            </executions>
        </plugin>
    </plugins>
</build>
```

This configuration ensures that:

- Kotlin code is compiled first.
- Java code is compiled after Kotlin and can reference Kotlin classes.
- Default Maven behavior doesn't override the plugin order.

For more details on how Maven handles plugin executions, see Guide to default plugin execution IDs in the official Maven documentation.

Compile Kotlin-only sources

To compile a project with just Kotlin source files, declare source roots and configure the Kotlin Maven plugin:

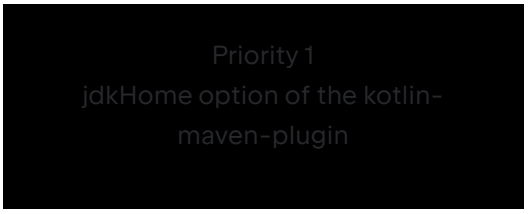
1. Specify the source directories in the `<build>` section:

```
<build>
    <sourceDirectory>src/main/kotlin</sourceDirectory>
    <testSourceDirectory>src/test/kotlin</testSourceDirectory>
</build>
```

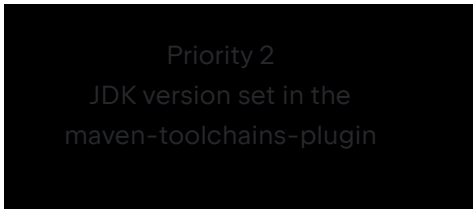
2. Ensure that the Kotlin Maven plugin is applied:

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>${kotlin.version}</version>
            <executions>
                <execution>
                    <id>compile</id>
                    <goals>
                        <goal>compile</goal>
                    </goals>
                </execution>
                <execution>
                    <id>test-compile</id>
                    <goals>
                        <goal>test-compile</goal>
                    </goals>
                </execution>
            </executions>
        </plugin>
    </plugins>
</build>
```

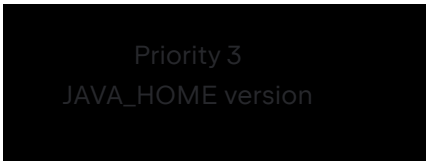
Set JDK version



Kotlin supports Maven Toolchains that help you manage the JDK version in your build.



If you configure the `maven-toolchains-plugin` in your build, you can specify the JDK version used for Kotlin compilation, independent of the JVM version running Maven (set in the `JAVA_HOME` path). The Kotlin Maven plugin then automatically picks up the selected JDK toolchain.



This allows you to configure a single toolchain that controls the JDK used across all plugins in the build, including Kotlin compilation. For example:

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-toolchains-plugin</artifactId>
    <version>3.2.0</version>
    <executions>
        <execution>
            <goals>
                <goal>toolchain</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <toolchains>
            <jdk>
                <version>21</version>
            </jdk>
        </toolchains>
    </configuration>
</plugin>
```

Keep in mind the priority of different ways to set up the JDK version:

- The JDK version set in the `jdkHome` option of the `kotlin-maven-plugin` configuration always takes precedence over the toolchain version.
- The JDK version in the `maven-toolchains-plugin` overrides the JDK version set in the `JAVA_HOME` path.

You can also use a plugin-specific `<jdkToolchain>` option to directly set the JDK version in the toolchain of the `kotlin-maven-plugin`. Compared to using the `maven-toolchains-plugin`, this parameter only affects Kotlin compilation and has no impact on other plugins in the build.

> Currently, setting up the `maven-toolchains-plugin` to use a specific JDK version does not affect the `kapt` and `test-kapt` goals of the `kotlin-maven-plugin`. Instead, set the necessary version in the `JAVA_HOME` path.

Configure Java modules (JPMS)

The Kotlin Maven plugin supports the Java Platform Module System (JPMS), so you can compile Kotlin code alongside a `module-info.java` descriptor and consume the resulting module like other Java modules.

You don't need any extra JPMS-specific options in the build file. Just configure the Kotlin compiler before Maven.

When a `module-info.java` descriptor is present, the Kotlin compiler uses it as a source file and compiles against its module path instead of the classpath. The Kotlin compiler reads the descriptor to resolve the module graph, and the Maven compiler then compiles it into a `module-info.class` file.

To configure a Java module, create the `module-info.java` file in the `${project.basedir}/src/main/java` directory. In the module descriptor, declare all the dependencies that your module requires and the packages it exports. For example:

```
module org.example.myapp {
    requires transitive kotlin.stdlib;
    requires java.net.http;

    exports org.example.myapp;
}
```

Keep in mind that:

- Your Java module can only use what you declare. Since compilation uses the module path instead of the classpath, the descriptor should include all dependencies that your Kotlin code uses: the standard library, JDK modules (except for `java.base`), and other libraries. Otherwise, you may get `Unresolved reference` errors.
- For a module, the package name in Kotlin files must match the package name from `module-info.java` to avoid the `Package is empty or does not exist` build failures.
- The `pom.xml` build file should be configured so that Kotlin is compiled before Java. If you use automatic project configuration, the `<extensions>` option already ensures this.

What's next?

Set dependencies in your Kotlin Maven project

Set repositories and dependencies in a Maven project

For your Kotlin Maven project, you can configure where Maven looks for artifacts beyond the default Maven Central repository and define the libraries your project depends on.

Declare repositories

By default, the `mavenCentral` repository is available for all Maven projects. To access artifacts in other repositories, specify a custom ID for the repository name and its URL in the `<repositories>` section:

```
<repositories>
    <repository>
        <id>spring-repo</id>
        <url>https://repo.spring.io/release</url>
    </repository>
</repositories>
```

If you declare `mavenLocal()` as a repository in a Gradle project, you may experience problems when switching between Gradle and Maven projects. For more information, see Declare repositories.

In general, to add a dependency on a library, you should declare a new `<dependency>` entry in the `<dependencies>` section:

```
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-serialization-json</artifactId>
        <version>1.11.0</version>
    </dependency>
</dependencies>
```

Set dependencies

Dependency on the standard library

Kotlin has an extensive standard library that you can use in your applications. You can add the standard library dependency manually or enable the `<extensions>` option to set it up automatically if it's missing.

Automatic setup

You can avoid manual configuration using the `<extensions>` option provided by the Kotlin Maven plugin. It automatically adds the `kotlin-stdlib` dependency if it's not defined in the project. For example, when you create a new Kotlin Maven project or introduce Kotlin to your existing Java Maven project.

If you already declared a dependency `kotlin-stdlib`, for example, with a different version, the Kotlin Maven plugin with `<extensions>` will not overwrite it.

You can also opt out from the automatic addition of the standard library. For that, add the following to the `<properties>` section:

```
<project>
    <properties>
        <kotlin.smart.defaults.enabled>false</kotlin.smart.defaults.enabled>
    </properties>
</project>
```

This property disables not only the automatic addition of the standard library, but also the registration of source root paths. Other `<extensions>` features are not affected.

Manual configuration

To manually add Kotlin's standard library to your project, update the `dependencies` section in your `pom.xml` file with the following:

```
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlin</groupId>
        <artifactId>kotlin-stdlib</artifactId>
        <!-- Uses kotlin.version specified in <properties/>: -->
        <version>${kotlin.version}</version>
    </dependency>
</dependencies>
```

If you're targeting JDK 7 or 8 with Kotlin versions older than:

- 1.8, use `kotlin-stdlib-jdk7` or `kotlin-stdlib-jdk8`, respectively.
- 1.2, use `kotlin-stdlib-jre7` or `kotlin-stdlib-jre8`, respectively.

Dependencies on test libraries

If your project uses Kotlin reflection or testing frameworks, add the relevant dependencies. Use `kotlin-reflect` for the reflection library, and `kotlin-test` and `kotlin-test-junit5` for testing libraries:

```
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlin</groupId>
        <artifactId>kotlin-reflect</artifactId>
        <version>${kotlin.version}</version>
    </dependency>
    <dependency>
        <groupId>org.jetbrains.kotlin</groupId>
        <artifactId>kotlin-test-junit5</artifactId>
        <scope>test</scope>
    </dependency>
</dependencies>
```

Dependency on a kotlinx library

For kotlinx libraries, you can either add the base artifact name or the name with a `-jvm` suffix. Refer to the library's README file on klibs.io.

For example, to add a dependency on `kotlinx.coroutines` library:

```
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-coroutines-core</artifactId>
        <version>1.11.0</version>
    </dependency>
</dependencies>
```

To add a dependency on the `kotlinx-datetime` library:

```
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlinx</groupId>
        <artifactId>kotlinx-datetime-jvm</artifactId>
        <version>0.8.0</version>
    </dependency>
</dependencies>
```

Manage dependencies with a BOM

A Bill of Materials (BOM) is a special POM file that manages dependency versions in your project. This keeps related artifacts aligned and avoids version conflicts.

Kotlin publishes the `kotlin-bom` artifact, which specifies the versions of Kotlin libraries, such as `kotlin-stdlib`, `kotlin-reflect`, and `kotlin-test`, that correspond to the same Kotlin release. This is useful when other libraries in your project have transitive dependencies on Kotlin artifacts because it ensures that all dependencies resolve to the same Kotlin version.

To use the Kotlin BOM, import it in the `<dependencyManagement>` section of your `pom.xml` file as follows:

```
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-bom</artifactId>
            <version>2.4.20</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>
```

After importing the BOM, you can declare Kotlin dependencies in the `<dependencies>` section without specifying their versions; they come from the BOM file automatically.

- Importing a BOM doesn't add any dependencies to your project on its own. It only controls the versions of explicitly declared and transitive dependencies.
- If you still specify a `<version>` for a dependency, that value overrides the version from the BOM.

If your project publishes several libraries that are released together, you can provide your own BOM so that users can align the versions of those libraries in the same way. To learn how to author your own BOM, see the Maven documentation.

What's next?

Configure Kotlin compiler

Configure Kotlin compiler for your Maven project

The `kotlin-maven-plugin` allows you to configure the Kotlin compiler for your Maven projects. You can specify compiler options, choose an execution strategy, and enable incremental compilation.

Specify compiler options

You can specify additional options and arguments for the compiler as elements in the `<configuration>` section of the Kotlin Maven plugin node:

```
<plugin>
    <groupId>org.jetbrains.kotlin</groupId>
    <artifactId>kotlin-maven-plugin</artifactId>
    <version>${kotlin.version}</version>
    <extensions>true</extensions> <!— If you want to enable automatic addition of executions to your
build —>
    <executions>...</executions>
    <configuration>
        <nowarn>true</nowarn> <!— Disable warnings —>
        <args>
            <arg>-Xjsr305=strict</arg> <!— Enable strict mode for JSR-305 annotations —>
            ...
        </args>
    </configuration>
</plugin>
```

Many of the options can also be configured through properties:

```
<project>
    <properties>
        <kotlin.compiler.languageVersion>2.4</kotlin.compiler.languageVersion>
    </properties>
</project>
```

The following attributes are supported:

Attributes specific to JVM

Name	Property name	Description	Possible values	Default value
`nowarn`		Generate no warnings	true, false	false
`languageVersion`	`kotlin.compiler.languageVersion`	Control which Kotlin language features and syntax are available during compilation. For more information, see `-language-version`.	"2.0", "2.1", "2.2", "2.3", "2.4", "2.5" (EXPERIMENTAL)	

Name	Property name	Description	Possible values	Default value
`apiVersion`	`kotlin.compiler.apiVersion`	Control which Kotlin APIs your code can use. For more information, see `-api-version`.	"2.0", "2.1", "2.2", "2.3", "2.4", "2.5" (EXPERIMENTAL)	
`sourceDirs`		The directories containing the source files to compile		The project source roots
`compilerPlugins`		Enabled compiler plugins		[]
`pluginOptions`		Options for compiler plugins		[]
`args`		Additional compiler arguments		[]
`jvmTarget`	`kotlin.compiler.jvmTarget`	Target JVM version of the generated bytecode. Controls only the bytecode version of the output and does not restrict which JDK APIs your code can use.	"1.8", "9", "10", ..., "26"	"1.8"
`jdkRelease`	`kotlin.compiler.jdkRelease`	Target JVM version. Controls the bytecode version and limits the available API to the specified JDK version, preventing accidental use of newer APIs. Equivalent to Java's `--release` compiler option.	"1.8", "9", "10", ..., "26"	
`jdkHome`	`kotlin.compiler.jdkHome`	Include a custom JDK from the specified location into the classpath instead of the default `JAVA_HOME`		
`jdkToolchain`	`kotlin.compiler.jdkToolchain`	Set the JDK version to use from the toolchain. Only affects Kotlin compilation		

Choose execution strategy

By default, Maven uses the Kotlin daemon compiler execution strategy. To switch to the "in process" strategy, set the following property in your `pom.xml` file:

```
<properties>
    <kotlin.compiler.daemon>false</kotlin.compiler.daemon>
</properties>
```

For more information about the different strategies, see Compiler execution strategy.

Enable incremental compilation

To make your builds faster, you can enable incremental compilation by adding the `kotlin.compiler.incremental` property:

```
<properties>
    <kotlin.compiler.incremental>true</kotlin.compiler.incremental>
</properties>
```

Alternatively, run your build with the `-Dkotlin.compiler.incremental=true` option.

What's next?

Package your project

Package your Maven application

To package your Kotlin application with Maven, you can create a standard JAR file or a self-contained (fat) JAR file that includes all its dependencies. Packaging your application allows you to distribute it and run it on any machine with a Java Runtime Environment (JRE).

Create JAR files

To create a small JAR file containing just the code from your module, include the following under `<build>` `<plugins>` in your Maven `pom.xml` file, where `main.class` is defined as a property and points to the main Kotlin or Java class:

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-jar-plugin</artifactId>
    <version>3.5.0</version>
    <configuration>
        <archive>
            <manifest>
                <addClasspath>true</addClasspath>
                <mainClass>${main.class}</mainClass>
            </manifest>
        </archive>
    </configuration>
</plugin>
```

Create self-contained JAR files

To create a self-contained JAR file containing the code from your module along with its dependencies, include the following under `<build><plugins>` in your Maven `pom.xml` file, where `main.class` is defined as a property and points to the main Kotlin or Java class:

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-assembly-plugin</artifactId>
    <version>3.8.0</version>
    <executions>
        <execution>
            <id>make-assembly</id>
            <phase>package</phase>
            <goals> <goal>single</goal> </goals>
            <configuration>
                <archive>
                    <manifest>
                        <mainClass>${main.class}</mainClass>
                    </manifest>
                </archive>
                <descriptorRefs>
                    <descriptorRef>jar-with-dependencies</descriptorRef>
                </descriptorRefs>
            </configuration>
        </execution>
    </executions>
</plugin>
```

This self-contained JAR file can be passed directly to a JRE to run your application:

```
java -jar target/mymodule-0.0.1-SNAPSHOT-jar-with-dependencies.jar
```

Beta

Build tools API

Kotlin has the Build tools API (BTA) that simplifies how build systems integrate with the Kotlin compiler.

Adding full Kotlin support to a build system (like incremental compilation, Kotlin compiler plugins, daemons, and Kotlin Multiplatform) requires significant effort. The BTA aims to reduce this complexity by providing a unified API between build systems and the Kotlin compiler ecosystem.

The BTA defines a single entry point that build systems can implement. This removes the need to deeply integrate with internal compiler details.

The stability level differs per target: the BTA is Beta for Kotlin/JVM, and Alpha for Kotlin/JS and Kotlin/Wasm. For more details, see Build tools API (BTA). Using the BTA requires an opt-in with `@OptIn(ExperimentalBuildToolsApi::class)`.

If you're interested in the proposal or want to share feedback, see the KEEP. Follow the status of its implementation in YouTrack.

Integration with Gradle

The Kotlin Gradle plugin (KGP) uses the BTA by default for Kotlin/JVM compilation.

> We'd appreciate your feedback on your experience with the KGP in YouTrack.

Enable the BTA for Kotlin/JS, Kotlin/Wasm, and Kotlin metadata

Since Kotlin 2.4.20, the KGP can also run Kotlin/JS, Kotlin/Wasm, and Kotlin metadata compilations through the BTA. This makes the KGP interact with the compiler more consistently, and in some cases compilation becomes faster and more stable.

In Kotlin 2.4.20, these targets are available as an opt-in. To try them out, add the corresponding properties to your `gradle.properties` file:

```
kotlin.js.runViaBuildToolsApi = true
kotlin.wasm.runViaBuildToolsApi = true
kotlin.metadata.runViaBuildToolsApi = true
```

Configure different compiler versions

With the BTA, you can now use a different Kotlin compiler version than the version used by the KGP. This is useful when:

- You want to try new Kotlin features but haven't updated your build scripts yet.
- You need the latest plugin fixes but want to stay on an older compiler version for now.

Here's an example of how to configure this in your `build.gradle.kts` file:

```
import org.jetbrains.kotlin.buildtools.api.ExperimentalBuildToolsApi
import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

plugins {
    kotlin("jvm") version "2.4.20"
}

group = "org.jetbrains.example"
version = "1.0-SNAPSHOT"

repositories {
    mavenCentral()
}

kotlin {
    jvmToolchain(8)
    @OptIn(ExperimentalBuildToolsApi::class, ExperimentalKotlinGradlePluginApi::class)
    compilerVersion.set("2.3.21") // <-- different version than 2.4.20
}
```

Compatible Kotlin compiler and KGP versions

The BTA supports:

- The three previous major Kotlin compiler versions.
- One major version forward.

For example, in KGP 2.2.0, the supported Kotlin compiler versions are:

- 1.9.25
- 2.0.x
- 2.1.x
- 2.2.x
- 2.3.x

Limitations

Using different compiler versions together with compiler plugins may lead to Kotlin compiler exceptions. The Kotlin team plans to address this in future Kotlin releases.

Enable incremental compilation with "in process" strategy

The KGP supports three compiler execution strategies. Ordinarily, the "in-process" strategy (which runs the compiler in the Gradle daemon) doesn't support incremental compilation.

With the BTA, the "in-process" strategy now supports incremental compilation. To enable it, add the following property to your `gradle.properties` file:

```
kotlin.compiler.execution.strategy=in-process
```

Integration with Maven

The BTA enables the `kotlin-maven-plugin` to support the Kotlin daemon, which is the default compiler execution strategy. The `kotlin-maven-plugin` uses BTA by default, so there's no need to configure anything.

The BTA makes it possible to deliver more features like Incremental compilation stabilization in the future.

Kotlin daemon

The Kotlin daemon is a background process that build systems can use to improve build times by keeping the compiler and its environment ready to compile. This approach avoids starting a new Java Virtual Machine (JVM) instance and reinitializing the compiler for every compilation, leading to reduced build times for incremental builds or frequent small changes.

Some build systems have their own daemons that help reduce startup costs, such as the Gradle daemon and the Maven daemon. Using the Kotlin daemon instead reduces startup costs while also completely isolating the build system process from the compiler. This separation is useful in dynamic environments where system settings might change at runtime.

Although the Kotlin daemon has no direct user-facing interface, you can use it through build systems or the build tools API.

Kotlin daemon configuration

There are ways to configure some settings for the Kotlin daemon for Gradle or Maven.

Memory management

The Kotlin daemon is a separate process that has its own memory space, isolated from the client. By default, the Kotlin daemon tries to inherit the heap size (`-Xmx`) of the launching JVM process.

To configure specific memory limits, like `-Xmx` and `-XX:MaxMetaspaceSize` , use the following property:

Gradle

```
kotlin.daemon.jvmargs=-Xmx1500m
```

For more information, see `kotlin.daemon.jvmargs` property.

Maven

```
<kotlin.compiler.daemon.jvmArgs>-Xmx1500m</kotlin.compiler.daemon.jvmArgs>
```

Lifetime

There are two common lifetime strategies for the Kotlin daemon:

- **Attached daemon**: Shut down the daemon shortly after the client process shuts down or the daemon hasn't been used for a while. Use when the client is long-running.
- **Detached daemon**: Keep the daemon alive longer to await potential follow-up requests. Use when the client is short-lived.

To configure the lifetime strategy, you can use the following options:

Option	Description	Default value
`autoshutdownIdleSeconds`	How long the daemon should stay alive after the last compilation when a client is still connected.	2 hours
`autoshutdownUnusedSeconds`	How long a newly started daemon waits for a first client before shutting down if unused.	1 minute
`shutdownDelayMilliseconds`	How long the daemon waits to shut down after all clients disconnect.	1 second

To configure an attached daemon lifetime strategy, set `autoshutdownIdleSeconds` to a **high** value and `shutdownDelayMilliseconds` to a **low** value.

Add the following to your `gradle.properties` file:

Gradle

```
org.gradle.jvmargs=-
Dkotlin.daemon.jvm.options=autoshutdownIdleSeconds=7200,shutdownDelayMilliseconds=1000
```

Use the following command:

Maven

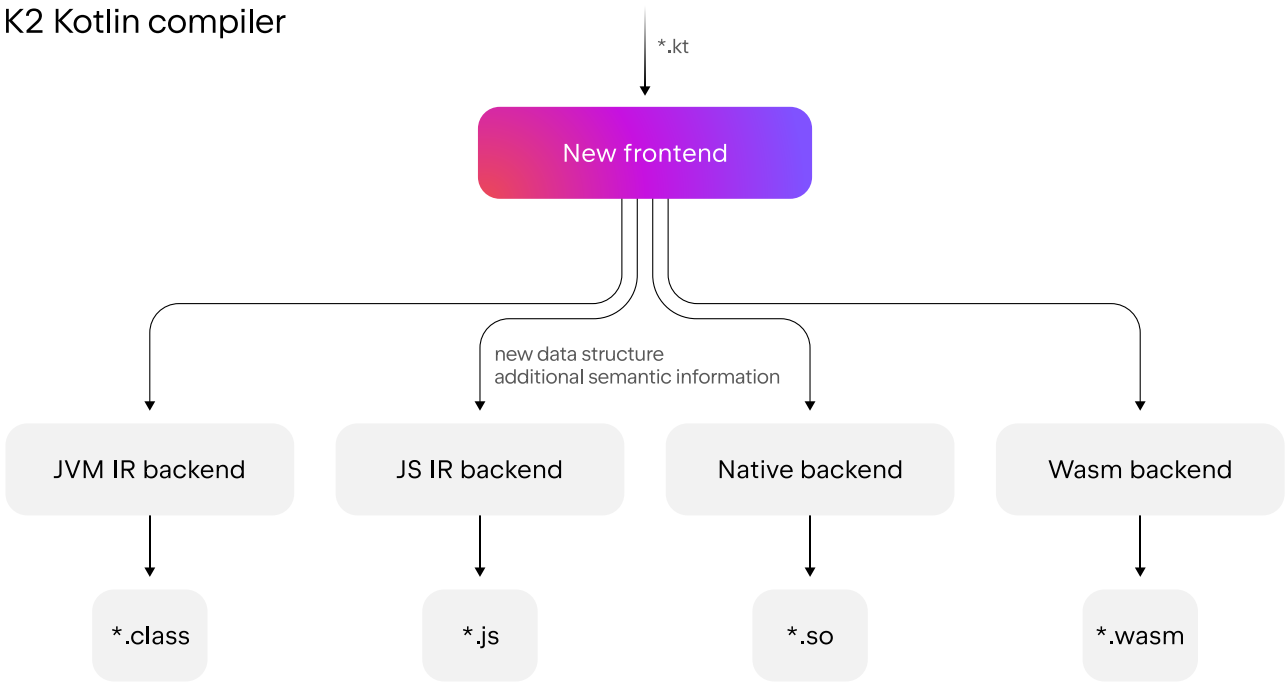
```
mvn package -Dkotlin.daemon.options=autoshutdownIdleSeconds=7200,shutdownDelayMilliseconds=1000
```

To configure a detached daemon lifetime strategy, set `shutdownDelayMilliseconds` to a **high** value.

Add the following to your `gradle.properties` file:

Gradle

```
org.gradle.jvmargs=-Dkotlin.daemon.jvm.options=shutdownDelayMilliseconds=7200
```



Add the following property to your `pom.xml` file:

Maven

```
<kotlin.compiler.daemon.shutdownDelayMs>7200</kotlin.compiler.daemon.shutdownDelayMs>
```

K2 compiler migration guide

As the Kotlin language and ecosystem have continued to evolve, so has the Kotlin compiler. The first step was the introduction of the new JVM and JS IR (Intermediate Representation) backends that share logic, simplifying code generation for targets on different platforms. Now, the next stage of its evolution brings a new frontend known as K2.

Kotlin K2 compiler architecture

With the arrival of the K2 compiler, the Kotlin frontend has been completely rewritten and features a new, more efficient architecture. The fundamental change the new compiler brings is the use of one unified data structure that contains more semantic information. This frontend is responsible for performing semantic analysis, call resolution, and type inference.

The new architecture and enriched data structure enables the K2 compiler to provide the following benefits:

- **Improved call resolution and type inference**. The compiler behaves more consistently and understands your code better.
- **Easier introduction of syntactic sugar for new language features**. In the future, you'll be able to use more concise, readable code when new features are introduced.
- **Faster compilation times**. Compilation times can be significantly faster.
- **Enhanced IDE performance**. IntelliJ IDEA and Android Studio use the K2 compiler to analyze your Kotlin code, increasing stability and providing performance improvements. For more information, see Support in IDEs.

This guide:

- Explains the benefits of the new K2 compiler.
- Highlights changes you might encounter during migration and how to adapt your code accordingly.
- Describes how you can roll back to the previous version.

The new K2 compiler is enabled by default starting with 2.0.0. For more information on the new features provided in Kotlin 2.0.0, as well as the new K2 compiler, see What's new in Kotlin 2.0.0.

Performance improvements

To evaluate the performance of the K2 compiler, we ran performance tests on two open-source projects: Anki-Android and Exposed. Here are the key performance improvements that we found:

- The K2 compiler brings up to 94% compilation speed gains. For example, in the Anki-Android project, clean build times were reduced from 57.7 seconds in Kotlin 1.9.23 to 29.7 seconds in Kotlin 2.0.0.
- The initialization phase is up to 488% faster with the K2 compiler. For example, in the Anki-Android project, the initialization phase for incremental builds was cut from 0.126 seconds in Kotlin 1.9.23 to just 0.022 seconds in Kotlin 2.0.0.
- The Kotlin K2 compiler is up to 376% quicker in the analysis phase compared to the previous compiler. For example, in the Anki-Android project, analysis times for incremental builds were slashed from 0.581 seconds in Kotlin 1.9.23 to only 0.122 seconds in Kotlin 2.0.0.

For more details on these improvements and to learn more about how we analyzed the performance of the K2 compiler, see our blog post.

Language feature improvements

The Kotlin K2 compiler improves language features related to smart-casting and Kotlin Multiplatform.

Smart casts

The Kotlin compiler can automatically cast an object to a type in specific cases, saving you the trouble of having to explicitly specify it yourself. This is called smart-casting. The Kotlin K2 compiler now performs smart casts in even more scenarios than before.

In Kotlin 2.0.0, we've made improvements related to smart casts in the following areas:

- Local variables and further scopes
- Type checks with the logical `or` operator
- Inline functions
- Properties with function types
- Exception handling
- Increment and decrement operators

Local variables and further scopes

Previously, if a variable was evaluated as not `null` within an `if` condition, the variable would be smart-cast. Information about this variable would then be shared further within the scope of the `if` block.

However, if you declared the variable **outside** the `if` condition, no information about the variable would be available within the `if` condition, so it couldn't be smart-cast. This behavior was also seen with `when` expressions and `while` loops.

From Kotlin 2.0.0, if you declare a variable before using it in your `if`, `when`, or `while` condition, then any information collected by the compiler about the variable will be accessible in the corresponding block for smart-casting.

This can be useful when you want to do things like extract boolean conditions into variables. Then, you can give the variable a meaningful name, which will improve your code readability and make it possible to reuse the variable later in your code. For example:

```
class Cat {
    fun purr() {
        println("Purr purr")
    }
}

fun petAnimal(animal: Any) {
    val isCat = animal is Cat
    if (isCat) {
        // In Kotlin 2.0.0, the compiler can access
        // information about isCat, so it knows that
        // animal was smart-cast to the type Cat.
        // Therefore, the purr() function can be called.
        // In Kotlin 1.9.20, the compiler doesn't know
        // about the smart cast, so calling the purr()
        // function triggers an error.
        animal.purr()
    }
}

fun main(){
    val kitty = Cat()
    petAnimal(kitty)
    // Purr purr
}
```

Type checks with the logical or operator

In Kotlin 2.0.0, if you combine type checks for objects with an `or` operator (`||`), a smart cast is made to their closest common supertype. Before this change, a smart cast was always made to the `Any` type.

In this case, you still had to manually check the object type afterward before you could access any of its properties or call its functions. For example:

```
interface Status {
    fun signal() {}
}

interface Ok : Status
interface Postponed : Status
interface Declined : Status

fun signalCheck(signalStatus: Any) {
    if (signalStatus is Postponed || signalStatus is Declined) {
        // signalStatus is smart-cast to a common supertype Status
        signalStatus.signal()
        // Prior to Kotlin 2.0.0, signalStatus is smart cast
        // to type Any, so calling the signal() function triggered an
        // Unresolved reference error. The signal() function can only
        // be called successfully after another type check:

        // check(signalStatus is Status)
        // signalStatus.signal()
    }
}
```

The common supertype is an **approximation** of a union type. Union types are not currently supported in Kotlin.

Inline functions

In Kotlin 2.0.0, the K2 compiler treats inline functions differently, allowing it to determine in combination with other compiler analyses whether it's safe to smart-cast.

Specifically, inline functions are now treated as having an implicit `callsInPlace` contract. This means that any lambda functions passed to an inline function are called in place. Since lambda functions are called in place, the compiler knows that a lambda function can't leak references to any variables contained within its function body.

The compiler uses this knowledge along with other compiler analyses to decide whether it's safe to smart-cast any of the captured variables. For example:

```
interface Processor {
    fun process()
}

inline fun inlineAction(f: () -> Unit) = f()

fun nextProcessor(): Processor? = null

fun runProcessor(): Processor? {
    var processor: Processor? = null
    inlineAction {
        // In Kotlin 2.0.0, the compiler knows that processor
        // is a local variable and inlineAction() is an inline function, so
        // references to processor can't be leaked. Therefore, it's safe
        // to smart-cast processor.

        // If processor isn't null, processor is smart-cast
        if (processor ≠ null) {
            // The compiler knows that processor isn't null, so no safe call
            // is needed
            processor.process()

            // In Kotlin 1.9.20, you have to perform a safe call:
            // processor?.process()
        }

        processor = nextProcessor()
    }

    return processor
}
```

Properties with function types

In previous versions of Kotlin, there was a bug that meant that class properties with a function type weren't smart-cast. We fixed this behavior in Kotlin 2.0.0 and the K2 compiler. For example:

```
class Holder(val provider: (() → Unit)?) {
    fun process() {
        // In Kotlin 2.0.0, if provider isn't null,
        // it is smart-cast
        if (provider ≠ null) {
            // The compiler knows that provider isn't null
            provider()

            // In 1.9.20, the compiler doesn't know that provider isn't
            // null, so it triggers an error:
            // Reference has a nullable type '(() → Unit)?', use explicit '?.invoke()' to make a
function-like call instead
        }
    }
}
```

This change also applies if you overload your `invoke` operator. For example:

```
interface Provider {
    operator fun invoke()
}

interface Processor : () → String

class Holder(val provider: Provider?, val processor: Processor?) {
    fun process() {
        if (provider ≠ null) {
            provider()
            // In 1.9.20, the compiler triggers an error:
            // Reference has a nullable type 'Provider?', use explicit '?.invoke()' to make a
function-like call instead
        }
    }
}
```

Exception handling

In Kotlin 2.0.0, we've made improvements to exception handling so that smart cast information can be passed on to `catch` and `finally` blocks. This change makes your code safer as the compiler keeps track of whether your object has a nullable type. For example:

```
fun testString() {
    var stringInput: String? = null
    // stringInput is smart-cast to String type
    stringInput = ""
    try {
        // The compiler knows that stringInput isn't null
        println(stringInput.length)
        // 0

        // The compiler rejects previous smart cast information for
        // stringInput. Now stringInput has the String? type.
        stringInput = null

        // Trigger an exception
        if (2 > 1) throw Exception()
        stringInput = ""
    } catch (exception: Exception) {
        // In Kotlin 2.0.0, the compiler knows stringInput
        // can be null, so stringInput stays nullable.
        println(stringInput?.length)
        // null

        // In Kotlin 1.9.20, the compiler says that a safe call isn't
        // needed, but this is incorrect.
    }
}
fun main() {
    testString()
}
```

Increment and decrement operators

Prior to Kotlin 2.0.0, the compiler didn't understand that the type of an object can change after using an increment or decrement operator. As the compiler couldn't accurately track the object type, your code could lead to unresolved reference errors. In Kotlin 2.0.0, this has been fixed:

```
interface Rho {
    operator fun inc(): Sigma = TODO()
}

interface Sigma : Rho {
    fun sigma() = Unit
}

interface Tau {
    fun tau() = Unit
}

fun main(input: Rho) {
    var unknownObject: Rho = input

    // Check if unknownObject inherits from the Tau interface
    // Note, it's possible that unknownObject inherits from both
    // Rho and Tau interfaces.
    if (unknownObject is Tau) {

        // Use the overloaded inc() operator from interface Rho.
        // In Kotlin 2.0.0, the type of unknownObject is smart-cast to
        // Sigma.
        ++unknownObject

        // In Kotlin 2.0.0, the compiler knows unknownObject has type
        // Sigma, so the sigma() function can be called successfully.
        unknownObject.sigma()

        // In Kotlin 1.9.20, the compiler doesn't perform a smart cast
        // when inc() is called so the compiler still thinks that
        // unknownObject has type Tau. Calling the sigma() function
        // throws a compile-time error.

        // In Kotlin 2.0.0, the compiler knows unknownObject has type
        // Sigma, so calling the tau() function throws a compile-time
        // error.
        unknownObject.tau()
        // Unresolved reference 'tau'

        // In Kotlin 1.9.20, since the compiler mistakenly thinks that
        // unknownObject has type Tau, the tau() function can be called,
        // but it throws a ClassCastException.
    }
}
```

Kotlin Multiplatform

There are improvements in the K2 compiler related to Kotlin Multiplatform in the following areas:

- Separation of common and platform sources during compilation
- Different visibility levels of expected and actual declarations

Separation of common and platform sources during compilation

Previously, the design of the Kotlin compiler prevented it from keeping common and platform source sets separate at compile time. As a consequence, common code could access platform code, which resulted in different behavior between platforms. In addition, some compiler settings and dependencies from common code used to leak into platform code.

In Kotlin 2.0.0, our implementation of the new Kotlin K2 compiler included a redesign of the compilation scheme to ensure strict separation between common and platform source sets. This change is most noticeable when you use expected and actual functions. Previously, it was possible for a function call in your common code to resolve to a function in platform code. For example:

Common code

```
fun foo(x: Any) = println("common
foo")

fun exampleFunction() {
    foo(42)
}
```

Platform code

```
// JVM
fun foo(x: Int) = println("platform foo")

// JavaScript
// There is no foo() function overload on the JavaScript
platform
```

In this example, the common code has different behavior depending on which platform it is run on:

- On the JVM platform, calling the `foo()` function in the common code results in the `foo()` function from the platform code being called as `platform foo`.
- On the JavaScript platform, calling the `foo()` function in the common code results in the `foo()` function from the common code being called as `common foo`, as there is no such function available in the platform code.

In Kotlin 2.0.0, common code doesn't have access to platform code, so both platforms successfully resolve the `foo()` function to the `foo()` function in the common code: `common foo`.

In addition to the improved consistency of behavior across platforms, we also worked hard to fix cases where there was conflicting behavior between IntelliJ IDEA or Android Studio and the compiler. For instance, when you used expected and actual classes, the following would happen:

Common code

```
expect class Identity {
    fun confirmIdentity(): String
}

fun common() {
    // Before 2.0.0, it triggers an IDE-only error
    Identity().confirmIdentity()
    // RESOLUTION_TO_CLASSIFIER : Expected class Identity
has no default constructor.
}
```

Platform code

```
actual class Identity {
    actual fun confirmIdentity() =
"expect class fun: jvm"
}
```

In this example, the expected class `Identity` has no default constructor, so it can't be called successfully in common code. Previously, an error was only reported by the IDE, but the code still compiled successfully on the JVM. However, now the compiler correctly reports an error:

```
Expected class 'expect class Identity : Any' does not have default constructor
```

When resolution behavior doesn't change

We're still in the process of migrating to the new compilation scheme, so the resolution behavior is still the same when you call functions that aren't within the same source set. You'll notice this difference mainly when you use overloads from a multiplatform library in your common code.

Suppose you have a library, which has two `whichFun()` functions with different signatures:

```
// Example library

// MODULE: common
fun whichFun(x: Any) = println("common function")

// MODULE: JVM
fun whichFun(x: Int) = println("platform function")
```

If you call the `whichFun()` function in your common code, the function that has the most relevant argument type in the library will be resolved:

```
// A project that uses the example library for the JVM target

// MODULE: common
fun main(){
    whichFun(2)
    // platform function
}
```

In comparison, if you declare the overloads for `whichFun()` within the same source set, the function from the common code will be resolved because your code doesn't have access to the platform-specific version:

```
// Example library isn't used

// MODULE: common
fun whichFun(x: Any) = println("common function")

fun main(){
    whichFun(2)
    // common function
}

// MODULE: JVM
fun whichFun(x: Int) = println("platform function")
```

Similar to multiplatform libraries, since the `commonTest` module is in a separate source set, it also still has access to platform-specific code. Therefore, the resolution of calls to functions in the `commonTest` module exhibits the same behavior as in the old compilation scheme.

In the future, these remaining cases will be more consistent with the new compilation scheme.

Different visibility levels of expected and actual declarations

Before Kotlin 2.0.0, if you used expected and actual declarations in your Kotlin Multiplatform project, they had to have the same visibility level. Kotlin 2.0.0 now also supports different visibility levels but **only** if the actual declaration is *more* permissive than the expected declaration. For example:

```
expect internal class Attribute // Visibility is internal
actual class Attribute          // Visibility is public by default,
                                // which is more permissive
```

Similarly, if you are using a type alias in your actual declaration, the visibility of the **underlying type** should be the same or more permissive than the expected declaration. For example:

```
expect internal class Attribute                 // Visibility is internal
internal actual typealias Attribute = Expanded

class Expanded                                  // Visibility is public by default,
                                                // which is more permissive
```

How to enable the Kotlin K2 compiler

Starting with Kotlin 2.0.0, the Kotlin K2 compiler is enabled by default.

To upgrade the Kotlin version, change it to 2.0.0 or a later release in your Gradle and Maven build scripts.

Use Kotlin build reports with Gradle

Kotlin build reports provide information about the time spent in different compilation phases for Kotlin compiler tasks, as well as which compiler and Kotlin version were used, and whether the compilation was incremental. These build reports are useful for assessing your build performance. They offer more insight into the Kotlin compilation pipeline than Gradle build scans do because they give you an overview of the performance of all Gradle tasks.

How to enable build reports

To enable build reports, declare where you'd like to save the build report output in your `gradle.properties` file:

```
kotlin.build.report.output=file
```

The following values and their combinations are available for the output:

Option	Description
`file`	Saves build reports in a human-readable format to a local file. By default, it's `${project_folder}/build/reports/kotlin-build/${project_name}-timestamp.txt`
`single_file`	Saves build reports in a format of an object to a specified local file.
`build_scan`	Saves build reports in the `custom values` section of the build scan. Note that the Gradle Enterprise plugin limits the number of custom values and their length. In big projects, some values could be lost.
`http`	Posts build reports using HTTP(S). The POST method sends metrics in JSON format. You can see the current version of the sent data in the Kotlin repository. You can find samples of HTTP endpoints in this blog post

Option	Description
`json`	Saves build reports in JSON format to a local file. Set the location for your build reports in `kotlin.build.report.json.directory`. By default, it's name is `${project_name}-build-<date-time>-<index>.json`.

For more information on what is possible with build reports, see Build reports.

Support in IDEs

Both IntelliJ IDEA and Android Studio fully support the K2 compiler and use it by default to improve code analysis, code completion, and highlighting. You don't need to configure anything. Update to the latest version to see the benefits.

Try the Kotlin K2 compiler in the Kotlin Playground

The Kotlin Playground supports Kotlin 2.0.0 and later releases. Check it out!

How to roll back to the previous compiler

To use the previous compiler in Kotlin 2.0.0–2.3.21, either:

- In your `build.gradle.kts` file, set your language version to `1.9`.

  OR

- Use the following compiler option: `-language-version 1.9`.

From Kotlin 2.4.0 onward, you can't roll back to the previous compiler.

Changes

With the introduction of the new frontend, the Kotlin compiler has undergone several changes. Let's start by highlighting the most significant modifications affecting your code, explaining what has changed and detailing best practices going forward. If you'd like to learn more, we've organized these changes into subject areas to facilitate your further reading.

This section highlights the following modifications:

- Immediate initialization of open properties with backing fields
- Deprecated synthetic setters on a projected receiver
- Forbidden use of inaccessible generic types
- Consistent resolution order of Kotlin properties and Java fields with the same name
- Improved null safety for Java primitive arrays
- Stricter rules for abstract members in expected classes

Immediate initialization of open properties with backing fields

What's changed?

In Kotlin 2.0, all `open` properties with backing fields must be immediately initialized; otherwise, you'll get a compilation error. Previously, only `open var` properties needed to be initialized right away, but now this extends to `open val` properties with backing fields too:

```
open class Base {
    open val a: Int
    open var b: Int

    init {
        // Error starting with Kotlin 2.0 that earlier compiled successfully
        this.a = 1 //Error: open val must have initializer
        // Always an error
        this.b = 1 // Error: open var must have initializer
    }
}

class Derived : Base() {
    override val a: Int = 2
    override var b = 2
}
```

This change makes the compiler's behavior more predictable. Consider an example where an `open val` property is overridden by a `var` property with a custom setter.

If a custom setter is used, deferred initialization can lead to confusion because it's unclear whether you want to initialize the backing field or to invoke the setter. In the past, if you wanted to invoke the setter, the old compiler couldn't guarantee that the setter would then initialize the backing field.

What's the best practice now?

We encourage you to always initialize open properties with backing fields, as we believe this practice is both more efficient and less error-prone.

However, if you don't want to immediately initialize a property, you can:

- Make the property `final`.
- Use a private backing property that allows for deferred initialization.

For more information, see the corresponding issue in YouTrack.

Deprecated synthetics setter on a projected receiver

What's changed?

If you use the synthetic setter of a Java class to assign a type that conflicts with the class's projected type, an error is triggered.

Suppose you have a Java class named `Container` that contains the `getFoo()` and `setFoo()` methods:

```
public class Container<E> {
    public E getFoo() {
        return null;
    }
    public void setFoo(E foo) {}
}
```

If you have the following Kotlin code, where instances of the `Container` class have projected types, using the `setFoo()` method will always generate an error. However, only from Kotlin 2.0.0 will the synthetic `foo` property trigger an error:

```
fun exampleFunction(starProjected: Container<*>, inProjected: Container<in Number>, sampleString:
String) {
    starProjected.setFoo(sampleString)
    // Error since Kotlin 1.0

    // Synthetic setter `foo` is resolved to the `setFoo()` method
    starProjected.foo = sampleString
    // Error since Kotlin 2.0.0

    inProjected.setFoo(sampleString)
    // Error since Kotlin 1.0

    // Synthetic setter `foo` is resolved to the `setFoo()` method
    inProjected.foo = sampleString
    // Error since Kotlin 2.0.0
}
```

What's the best practice now?

If you see that this change introduces errors in your code, you might wish to reconsider how you structure your type declarations. It could be that you don't need to use type projections, or perhaps you need to remove any assignments from your code.

For more information, see the corresponding issue in YouTrack.

Forbidden use of inaccessible generic types

What's changed?

Due to the new architecture of our K2 compiler, we've changed how we handle inaccessible generic types. Generally, you should never rely on inaccessible generic types in your code because this indicates a misconfiguration in your project's build configuration, preventing the compiler from accessing the necessary information to compile. In Kotlin 2.0.0, you can't declare or call a function literal with an inaccessible generic type, nor use a generic type with inaccessible generic type arguments. This restriction helps you avoid compiler errors later in your code.

For example, let's say that you declared a generic class in one module:

```
// Module one
class Node<V>(val value: V)
```

If you have another module (module two) with a dependency configured on module one, your code can access the `Node<V>` class and use it as a type in function types:

```
// Module two
fun execute(func: (Node<Int>) -> Unit) {}
// Function compiles successfully
```

However, if your project is misconfigured such that you have a third module (module three) that depends only on module two, the Kotlin compiler won't be able to access the `Node<V>` class in **module one** when compiling the third module. Now, any lambdas or anonymous functions in module three that use the `Node<V>` type trigger errors in Kotlin 2.0.0, thus preventing avoidable compiler errors, crashes, and run-time exceptions later in your code:

```
// Module three
fun test() {
    // Triggers an error in Kotlin 2.0.0, as the type of the implicit
    // lambda parameter (it) resolves to Node, which is inaccessible
    execute {}

    // Triggers an error in Kotlin 2.0.0, as the type of the unused
    // lambda parameter (_) resolves to Node, which is inaccessible
    execute { _ -> }

    // Triggers an error in Kotlin 2.0.0, as the type of the unused
    // anonymous function parameter (_) resolves to Node, which is inaccessible
    execute(fun (_) {})
}
```

In addition to function literals triggering errors when they contain value parameters of inaccessible generic types, errors also occur when a type has an inaccessible generic type argument.

For example, you have the same generic class declaration in module one. In module two, you declare another generic class: `Container<C>`. In addition, you declare functions in module two that use `Container<C>` with generic class `Node<V>` as a type argument:

Module one

```
// Module one
class Node<V>(val value: V)
```

Module two

```
// Module two
class Container<C>(vararg val content: C)

// Functions with generic class type that
// also have a generic class type argument
fun produce(): Container<Node<Int>> = Container(Node(42))
fun consume(arg: Container<Node<Int>>) {}
```

If you try to call these functions in module three, an error is triggered in Kotlin 2.0.0 because the generic class `Node<V>` is inaccessible from module three:

```
// Module three
fun test() {
    // Triggers an error in Kotlin 2.0.0, as generic class Node<V> is
    // inaccessible
    consume(produce())
}
```

In future releases, we will continue to deprecate the use of inaccessible types in general. We have already started in Kotlin 2.0.0 by adding warnings for some scenarios with inaccessible types, including non-generic ones.

For example, let's use the same module setup as the previous examples, but turn the generic class `Node<V>` into a non-generic class `IntNode`, with all functions declared in module two:

Module one

```
// Module one
class IntNode(val value: Int)
```

Module two

```
// Module two
// A function that contains a lambda
// parameter with `IntNode` type
fun execute(func: (IntNode) -> Unit) {}

class Container<C>(vararg val content: C)

// Functions with generic class type
// that has `IntNode` as a type argument
fun produce(): Container<IntNode> = Container(IntNode(42))
fun consume(arg: Container<IntNode>) {}
```

If you call these functions in module three, some warnings are triggered:

```
// Module three
fun test() {
    // Triggers warnings in Kotlin 2.0.0, as class IntNode is
    // inaccessible.

    execute {}
    // Class 'IntNode' of the parameter 'it' is inaccessible.

    execute { _ -> }
    execute(fun (_) {})
    // Class 'IntNode' of the parameter '_' is inaccessible.

    // Will trigger a warning in future Kotlin releases, as IntNode is
    // inaccessible.
    consume(produce())
}
```

What's the best practice now?

If you encounter new warnings regarding inaccessible generic types, it's highly likely that there's an issue with your build system configuration. We recommend checking your build scripts and configuration.

As a last resort, you can configure a direct dependency for module three on module one. Alternatively, you can modify your code to make the types accessible within the same module.

For more information, see the corresponding issue in YouTrack.

Consistent resolution order of Kotlin properties and Java fields with the same name

What's changed?

Before Kotlin 2.0.0, if you worked with Java and Kotlin classes that inherited from each other and contained Kotlin properties and Java fields with the same name, the resolution behavior of the duplicated name was inconsistent. There was also conflicting behavior between IntelliJ IDEA and the compiler. When developing the new resolution behavior for Kotlin 2.0.0, we aimed to cause the least impact to users.

For example, suppose there is a Java class `Base`:

```java
public class Base {
    public String a = "a";

    public String b = "b";
}
```

Let's say there is also a Kotlin class `Derived` that inherits from the aforementioned `Base` class:

```kotlin
class Derived : Base() {
    val a = "aa"

    // Declares custom get() function
    val b get() = "bb"
}

fun main() {
    // Resolves Derived.a
    println(a)
    // aa

    // Resolves Base.b
    println(b)
    // b
}
```

Prior to Kotlin 2.0.0, `a` resolves to the Kotlin property within the `Derived` Kotlin class, whereas `b` resolves to the Java field in the `Base` Java class.

In Kotlin 2.0.0, the resolution behavior in the example is consistent, ensuring that the Kotlin property supersedes the Java field of the same name. Now, `b` resolves to: `Derived.b`.

Prior to Kotlin 2.0.0, if you used IntelliJ IDEA to go to the declaration or usage of `a`, it would incorrectly navigate to the Java field when it should have navigated to the Kotlin property.

From Kotlin 2.0.0, IntelliJ IDEA correctly navigates to the same location as the compiler.

The general rule is that the subclass takes precedence. The previous example demonstrates this, as the Kotlin property `a` from the `Derived` class is resolved because `Derived` is a subclass of the `Base` Java class.

In the event that the inheritance is reversed and a Java class inherits from a Kotlin class, the Java field in the subclass takes precedence over the Kotlin property with the same name.

Consider this example:

Kotlin

```kotlin
open class Base {
    val a = "aa"
}
```

Java

```java
public class Derived extends Base {
    public String a = "a";
}
```

Now in the following code:

```
fun main() {
    // Resolves Derived.a
    println(a)
    // a
}
```

What's the best practice now?

If this change affects your code, consider whether you really need to use duplicate names. If you want to have Java or Kotlin classes that each contain a field or property with the same name and that each inherit from one another, keep in mind that the field or property in the subclass will take precedence.

For more information, see the corresponding issue in YouTrack.

Improved null safety for Java primitive arrays

What's changed?

Starting with Kotlin 2.0.0, the compiler correctly infers the nullability of Java primitive arrays imported to Kotlin. Now, it retains native nullability from the `TYPE_USE` annotations used with Java primitive arrays and emits errors when their values are not used according to annotations.

Usually, when Java types with `@Nullable` and `@NotNull` annotations are called from Kotlin, they receive the appropriate native nullability:

```
interface DataService {
    @NotNull ResultContainer<@Nullable String> fetchData();
}
```

```
val dataService: DataService = ...
dataService.fetchData() // → ResultContainer<String?>
```

Previously, however, when Java primitive arrays were imported to Kotlin, all `TYPE_USE` annotations were lost, resulting in platform nullability and possibly unsafe code:

```
interface DataProvider {
    int @Nullable [] fetchData();
}
```

```
val dataService: DataProvider = ...
dataService.fetchData() // → IntArray .. IntArray?
// No error, even though `dataService.fetchData()` might be `null` according to annotations
// This might result in a NullPointerException
dataService.fetchData()[0]
```

Note that this issue never affected nullability annotations on the declaration itself, only the `TYPE_USE` ones.

What's the best practice now?

In Kotlin 2.0.0, null safety for Java primitive arrays is now standard in Kotlin, so check your code for new warnings and errors if you use them:

- Any code that uses a `@Nullable` Java primitive array without an explicit nullability check or attempts to pass `null` to a Java method expecting a non-nullable primitive array will now fail to compile.
- Using a `@NotNull` primitive array with a nullability check now emits "Unnecessary safe call" or "Comparison with null always false" warnings.

For more information, see the corresponding issue in YouTrack.

Stricter rules for abstract members in expected classes

Expected and actual classes are in Beta. They are almost stable, but you may need to perform migration steps in the future. We'll do our best to minimize any further changes for you to make.

What's changed?

Due to the separation of common and platform sources during compilation with the K2 compiler, we've implemented stricter rules for abstract members in expected classes.

With the previous compiler, it was possible for an expected non-abstract class to inherit an abstract function without overriding the function. Since the compiler could access both common and platform code at the same time, the compiler could see whether the abstract function had a corresponding override and definition in the actual class.

Now that common and platform sources are compiled separately, the inherited function must be explicitly overridden in the expected class so that the compiler knows the function is not abstract. Otherwise, the compiler reports an `ABSTRACT_MEMBER_NOT_IMPLEMENTED` error.

For example, let's say you have a common source set where you declare an abstract class called `FileSystem` that has an abstract function `listFiles()`. You define the `listFiles()` function in the platform source set as part of an actual declaration.

In your common code, if you have an expected non-abstract class called `PlatformFileSystem` that inherits from the `FileSystem` class, the `PlatformFileSystem` class inherits the abstract function `listFiles()`. However, you can't have an abstract function in a non-abstract class in Kotlin. To make the `listFiles()` function non-abstract, you must declare it as an override without the `abstract` keyword:

Common code

```
abstract class FileSystem {
    abstract fun listFiles()
}
expect open class PlatformFileSystem() :
FileSystem {
    // In Kotlin 2.0.0, an explicit override is
needed
    expect override fun listFiles()
    // Before Kotlin 2.0.0, an override wasn't
needed
}
```

Platform code

```
actual open class PlatformFileSystem :
FileSystem {
    actual override fun listFiles() {}
}
```

What's the best practice now?

If you inherit abstract functions in an expected non-abstract class, add a non-abstract override.

For more information, see the corresponding issue in YouTrack.

Per subject area

These subject areas list changes that are unlikely to affect your code but provide links to the relevant YouTrack issues for further reading. Changes listed with an asterisk (*) next to the Issue ID are explained at the beginning of the section.

Type inference

Issue ID	Title
KT-64189	Incorrect type in compiled function signature of property reference if the type is Normal explicitly
KT-47986	Forbid implicit inferring a type variable into an upper bound in the builder inference context
KT-59275	K2: Require explicit type arguments for generic annotation calls in array literals
KT-53752	Missed subtyping check for an intersection type
KT-59138	Change Java type parameter based types default representation in Kotlin
KT-57178	Change inferred type of prefix increment to return type of getter instead of return type of inc() operator
KT-57609	K2: Stop relying on the presence of @UnsafeVariance using for contravariant parameters
KT-57620	K2: Forbid resolution to subsumed members for raw types
KT-64641	K2: Properly inferred type of callable reference to a callable with extension-function parameter
KT-57011	Make real type of a destructuring variable consistent with explicit type when specified
KT-38895	K2: Fix inconsistent behavior with integer literals overflow
KT-54862	Anonymous type can be exposed from anonymous function from type argument
KT-22379	Condition of while-loop with break can produce unsound smartcast
KT-62507	K2: Prohibit smart cast in common code for expect/actual top-level property
KT-65750	Increment and plus operators that change return type must affect smart casts
KT-65349	[LC] K2: specifying variable types explicitly breaks bound smart casts in some cases that worked in K1

Generics

Issue ID	Title
KT-54309*	Deprecate use of a synthetic setter on a projected receiver
KT-57600	Forbid overriding of Java method with raw-typed parameter with generic typed parameter
KT-54663	Forbid passing possibly nullable type parameter to `in` projected DNN parameter
KT-54066	Deprecate upper bound violation in typealias constructors
KT-49404	Fix type unsoundness for contravariant captured type based on Java class
KT-61718	Forbid unsound code with self upper bounds and captured types
KT-61749	Forbid unsound bound violation in generic inner class of generic outer class
KT-62923	K2: Introduce PROJECTION_IN_IMMEDIATE_ARGUMENT_TO_SUPERTYPE for projections of outer super types of inner class
KT-63243	Report MANY_IMPL_MEMBER_NOT_IMPLEMENTED when inheriting from collection of primitives with an extra specialized implementation from another supertype
KT-60305	K2: Prohibit constructor call and inheritance on type alias that has variance modifiers in expanded type
KT-64965	Fix type hole caused by improper handling of captured types with self-upper bounds
KT-64966	Forbid generic delegating constructor calls with wrong type for generic parameter
KT-65712	Report missing upper bound violation when upper bound is captured type

Resolution

Issue ID	Title
KT-55017*	Choose Kotlin property from derived class during overload resolution with Java field from base class
KT-58260	Make invoke convention works consistently with expected desugaring
KT-62866	K2: Change qualifier resolution behavior when companion object is preferred against static scope
KT-57750	Report ambiguity error when resolving types and having the same-named classes star imported
KT-63558	K2: migrate resolution around COMPATIBILITY_WARNING
KT-51194	False negative CONFLICTING_INHERITED_MEMBERS when dependency class contained in two different versions of the same dependency
KT-37592	Property invoke of a functional type with receiver is preferred over extension function invoke
KT-51666	Qualified this: introduce/prioritize this qualified with type case
KT-54166	Confirm unspecified behavior in case of FQ name conflicts in classpath
KT-64431	K2: forbid using typealiases as qualifier in imports
KT-56520	K1/K2: incorrect work of resolve tower for type references with ambiguity at lower level

Visibility

Issue ID	Title
KT-64474*	Declare usages of inaccessible types as unspecified behavior
KT-55179	False negative PRIVATE_CLASS_MEMBER_FROM_INLINE on calling private class companion object member from internal inline function

Issue ID	Title
KT-58042	Make synthetic property invisible if equivalent getter is invisible even when overridden declaration is visible
KT-64255	Forbid accessing internal setter from a derived class in another module
KT-33917	Prohibit to expose anonymous types from private inline functions
KT-54997	Forbid implicit non-public-API accesses from public-API inline function
KT-56310	Smart casts should not affect visibility of protected members
KT-65494	Forbid access to overlooked private operator functions from public inline function
KT-65004	K1: Setter of var, which overrides protected val, is generates as public
KT-64972	Forbid overriding by private members in link-time for Kotlin/Native

Annotations

Issue ID	Title
KT-58723	Forbid annotating statements with an annotation if it has no EXPRESSION target
KT-49930	Ignore parentheses expression during `REPEATED_ANNOTATION` checking
KT-57422	K2: Prohibit use-site 'get' targeted annotations on property getters
KT-46483	Prohibit annotation on type parameter in where clause
KT-64299	Companion scope is ignored for resolution of annotations on companion object
KT-64654	K2: Introduced ambiguity between user and compiler-required annotations
KT-64527	Annotations on enum values shouldn't be copied to enum value classes

KT-63389	K2: `WRONG_ANNOTATION_TARGET` is reported on incompatible annotations of a type wrapped into `()?`
KT-63388	K2: `WRONG_ANNOTATION_TARGET` is reported on catch parameter type's annotations

Null safety

Issue ID	Title
KT-54521*	Deprecate unsafe usages of array types annotated as Nullable in Java
KT-41034	K2: Change evaluation semantics for combination of safe calls and convention operators
KT-50850	Order of supertypes defines nullability parameters of inherited functions
KT-53982	Keep nullability when approximating local types in public signatures
KT-62998	Forbid assignment of a nullable to a not-null Java field as a selector of unsafe assignment
KT-63209	Report missing errors for error-level nullable arguments of warning-level Java types

Java interoperability

Issue ID	Title
KT-53061	Forbid Java and Kotlin classes with the same FQ name in sources
KT-49882	Classes inherited from Java collections have inconsistent behavior depending on order of supertypes
KT-66324	K2: unspecified behavior in case of Java class inheritance from a Kotlin private class
KT-66220	Passing java vararg method to inline function leads to array of arrays in runtime instead of just an array
KT-66204	Allow to override internal members in K-J-K hierarchy

Properties

Issue ID	Title
KT-57555*	[LC] Forbid deferred initialization of open properties with backing field

Issue ID	Title
KT-58589	Deprecate missed MUST_BE_INITIALIZED when no primary constructor is presented or when class is local
KT-64295	Forbid recursive resolve in case of potential invoke calls on properties
KT-57290	Deprecate smart cast on base class property from invisible derived class if base class is from another module
KT-62661	K2: Missed OPT_IN_USAGE_ERROR for data class properties

Control flow

Issue ID	Title
KT-56408	Inconsistent rules of CFA in class initialization block between K1 and K2
KT-57871	K1/K2 inconsistency on if-conditional without else-branch in parenthesis
KT-42995	False negative "VAL_REASSIGNMENT" in try/catch block with initialization in scope function
KT-65724	Propagate data flow information from try block to catch and finally blocks

Enum classes

Issue ID	Title
KT-57608	Prohibit access to the companion object of enum class during initialization of enum entry
KT-34372	Report missed error for virtual inline method in enum classes
KT-52802	Report ambiguity resolving between property/field and enum entry
KT-47310	Change qualifier resolution behavior when companion property is preferred against enum entry

Functional (SAM) interfaces

Issue ID	Title
KT-52628	Deprecate SAM constructor usages which require OptIn without annotation

Issue ID	Title
KT-57014	Prohibit returning values with incorrect nullability from lambda for SAM constructor of JDK function interfaces
KT-64342	SAM conversion of parameter types of callable references leads to CCE

Companion object

Issue ID	Title
KT-54316	Out-of-call reference to companion object's member has invalid signature
KT-47313	Change (V)::foo reference resolution when V has a companion

Miscellaneous

Issue ID	Title
KT-59739*	K2/MPP reports [ABSTRACT_MEMBER_NOT_IMPLEMENTED] for inheritor in common code when the implementation is located in the actual counterpart
KT-49015	Qualified this: change behavior in case of potential label conflicts
KT-56545	Fix incorrect functions mangling in JVM backend in case of accidental clashing overload in a Java subclass
KT-62019	[LC issue] Prohibit suspend-marked anonymous function declarations in statement positions
KT-55111	OptIn: forbid constructor calls with default arguments (parameters with default values) under marker
KT-61182	Unit conversion is accidentally allowed to be used for expressions on variables + invoke resolution
KT-55199	Forbid promoting callable references with adaptations to KFunction
KT-65776	[LC] K2 breaks `false && ...` and `false || ...`
KT-65682	[LC] Deprecate `header`/`impl` keywords

Issue ID	Title
KT-45375	Generate all Kotlin lambdas via invokedynamic + LambdaMetafactory by default

Compatibility with Kotlin releases

The following Kotlin releases have support for the new K2 compiler:

Kotlin release	Stability level
2.0.0–2.4.20	Stable
1.9.20–1.9.25	Beta
1.9.0–1.9.10	JVM is Beta
1.7.0–1.8.22	Alpha

Compatibility with Kotlin libraries

If you're working with Kotlin/JVM, the K2 compiler works with libraries compiled with any version of Kotlin.

If you're working with Kotlin Multiplatform, the K2 compiler is guaranteed to work with libraries compiled with Kotlin version 1.9.20 and onwards.

Compiler plugins support

Currently, the Kotlin K2 compiler supports the following Kotlin compiler plugins:

- `all-open`
- AtomicFU
- `jvm-abi-gen`
- `js-plain-objects`
- kapt
- Lombok
- `no-arg`
- Parcelize
- Power-assert
- SAM with receiver
- Serialization

In addition, the Kotlin K2 compiler supports:

- The Jetpack Compose 1.5.0 compiler plugin and later versions.
- Kotlin Symbol Processing (KSP) since KSP2.

If you use any additional compiler plugins, check their documentation to see if they are compatible with K2.

Upgrade your custom compiler plugins

Custom compiler plugins use the plugin API, which is Experimental. As a result, the API may change at any time, so we can't guarantee backward compatibility.

The upgrade process has two paths depending on the type of custom plugin you have.

Backend-only compiler plugins

If your plugin implements only `IrGenerationExtension` extension points, the process is the same as for any other new compiler release. Check if there are any changes to the API that you use and make changes if necessary.

Backend and frontend compiler plugins

If your plugin uses frontend-related extension points, you need to rewrite the plugin using the new K2 compiler API. For an introduction to the new API, see FIR Plugin API.

If you have questions about upgrading your custom compiler plugin, join our #compiler Slack channel, and we will do our best to help you.

Share your feedback on the new K2 compiler

We would appreciate any feedback you may have!

- Report any problems you face migrating to the new K2 compiler in our issue tracker.
- Enable the Send usage statistics option to allow JetBrains to collect anonymous data about K2 usage.

Kotlin command-line compiler

Every Kotlin release ships with a standalone version of the compiler. You can download the latest version manually or via a package manager.

Installing the command-line compiler is not an essential step to use Kotlin. The common approach is to write Kotlin applications using IDEs or code editors with official Kotlin support, such as IntelliJ IDEA or Android Studio. They provide full Kotlin support right out of the box.

Learn how to get started with Kotlin in an IDE.

Install the compiler

Manual install

To install the Kotlin compiler manually:

1. Download the latest version (`kotlin-compiler-2.4.20.zip`) from GitHub Releases.
2. Unzip the standalone compiler into a directory and optionally add the `kotlinc/bin` directory to the system path. The `bin` directory contains the scripts needed to compile and run Kotlin on Windows, macOS, and Linux.

If you want to use the Kotlin command-line compiler on Windows, we recommend installing it manually.

SDKMAN!

An easier way to install Kotlin on UNIX-based systems, such as macOS, Linux, Cygwin, FreeBSD, and Solaris, is SDKMAN!. It also works in Bash and ZSH shells. Learn how to install SDKMAN!.

To install the Kotlin compiler via SDKMAN!, run the following command in the terminal:

```
sdk install kotlin
```

Homebrew

Alternatively, on macOS you can install the compiler via Homebrew:

```
brew update
brew install kotlin
```

Snap package

If you use Snap on Ubuntu 16.04 or later, you can install the compiler from the command line:

```
sudo snap install --classic kotlin
```

Create and run an application

1. Create a simple console JVM application in Kotlin that displays `"Hello, World!"`. In a code editor, create a new file called `hello.kt` with the following code:

   ```
   fun main() {
       println("Hello, World!")
   }
   ```

2. Compile the application using the Kotlin compiler:

   ```
   kotlinc hello.kt -include-runtime -d hello.jar
   ```

   - The `-d` option indicates the output path for generated class files, which may be either a directory or a **.jar** file.

- The `-include-runtime` option makes the resulting **.jar** file self-contained and runnable by including the Kotlin runtime library in it.

To see all available options, run:

```
kotlinc -help
```

3. Run the application:

```
java -jar hello.jar
```

To compile a Kotlin/Native application, use the Kotlin/Native compiler.

Compile a library

If you're developing a library to be used by other Kotlin applications, you can build the **.jar** file without including the Kotlin runtime:

```
kotlinc hello.kt -d hello.jar
```

Since binaries compiled this way depend on the Kotlin runtime, you should ensure that it is present in the classpath whenever your compiled library is used.

You can also use the `kotlinr` script to run binaries produced by the Kotlin compiler:

```
kotlinr -classpath hello.jar HelloKt
```

`HelloKt` is the main class name that the Kotlin compiler generates for the file named `hello.kt`.

To compile a Kotlin/Native library, use the Kotlin/Native compiler.

Run the REPL

Run the compiler with the `-Xrepl` compiler option to have an interactive shell. In this shell, you can type any valid Kotlin code and see the results.

Run scripts

You can use Kotlin as a scripting language. A Kotlin script is a Kotlin source file (`.kts`) with top-level executable code.

```
import java.io.File

// Get the passed in path, i.e. "-d some/path" or use the current path.
val path = if (args.contains("-d")) args[1 + args.indexOf("-d")]
           else "."

val folders = File(path).listFiles { file -> file.isDirectory() }
folders?.forEach { folder -> println(folder) }
```

To run a script, pass the `-script` option to the compiler with the corresponding script file:

```
kotlinc -script list_folders.kts -- -d <path_to_folder_to_inspect>
```

Kotlin provides experimental support for script customization, such as adding external properties, providing static or dynamic dependencies, and so on. Customizations are defined by so-called *script definitions* – annotated kotlin classes with the appropriate support code. The script filename extension is used to select the appropriate definition. Learn more about Kotlin custom scripting.

Properly prepared script definitions are detected and applied automatically when the appropriate jars are included in the compilation classpath. Alternatively, you can specify definitions manually by passing the `-script-templates` option to the compiler:

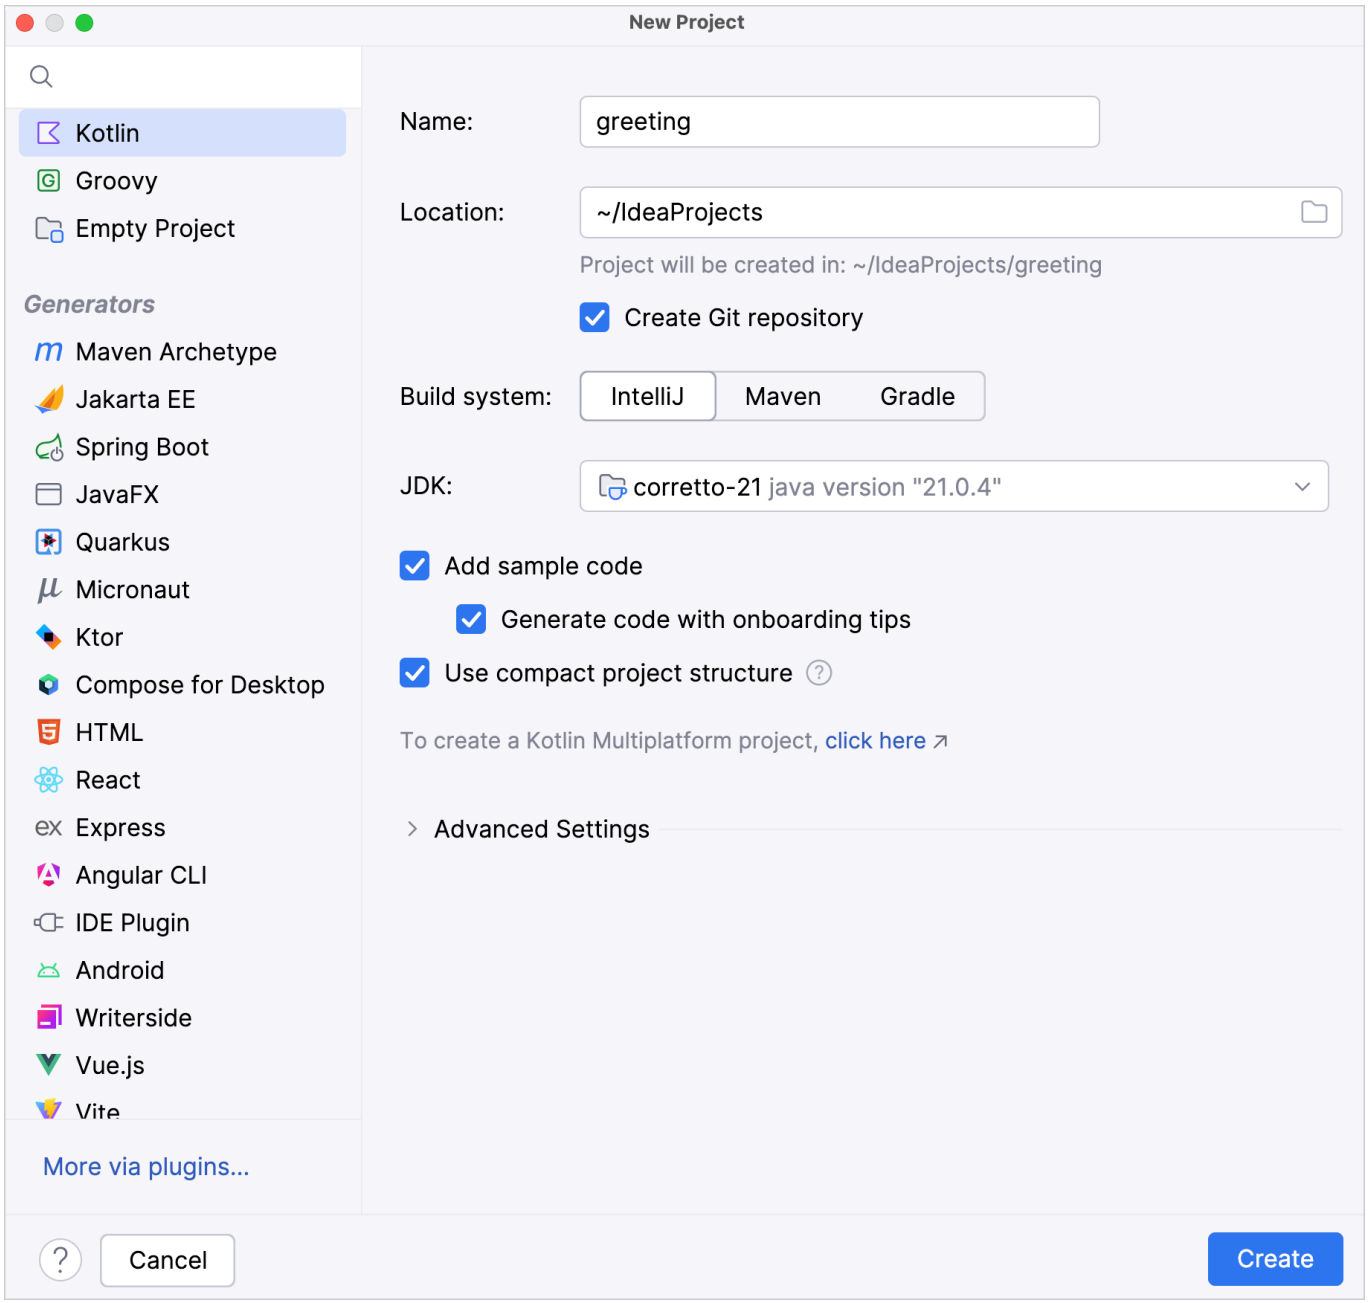
```
kotlinc -script-templates org.example.CustomScriptDefinition -script custom.script1.kts
```

For additional details, see the KEEP-75.

What's next?

Create a console application based on Kotlin/JVM.

Create a console app – tutorial



This tutorial demonstrates how to use IntelliJ IDEA for creating a console application.

To get started, first download and install the latest version of IntelliJ IDEA.

Create a project

1. In IntelliJ IDEA, select **File** | **New** | **Project**.
2. In the list on the left, select **Kotlin**.
3. Name the new project and change its location if necessary.

> Select the **Create Git repository** checkbox to place the new project under version control. You will be able to do it later at any time.

Create a console application

4. Select the **IntelliJ** build system. It's a native builder that doesn't require downloading additional artifacts.

   If you want to create a more complex project that needs further configuration, select Maven or Gradle. For Gradle, choose a language for the build script: Kotlin or Groovy.

5. From the **JDK** list, select the JDK that you want to use in your project.

   - If the JDK is installed on your computer, but not defined in the IDE, select **Add JDK** and specify the path to the JDK home directory.
   - If you don't have the necessary JDK on your computer, select **Download JDK**.

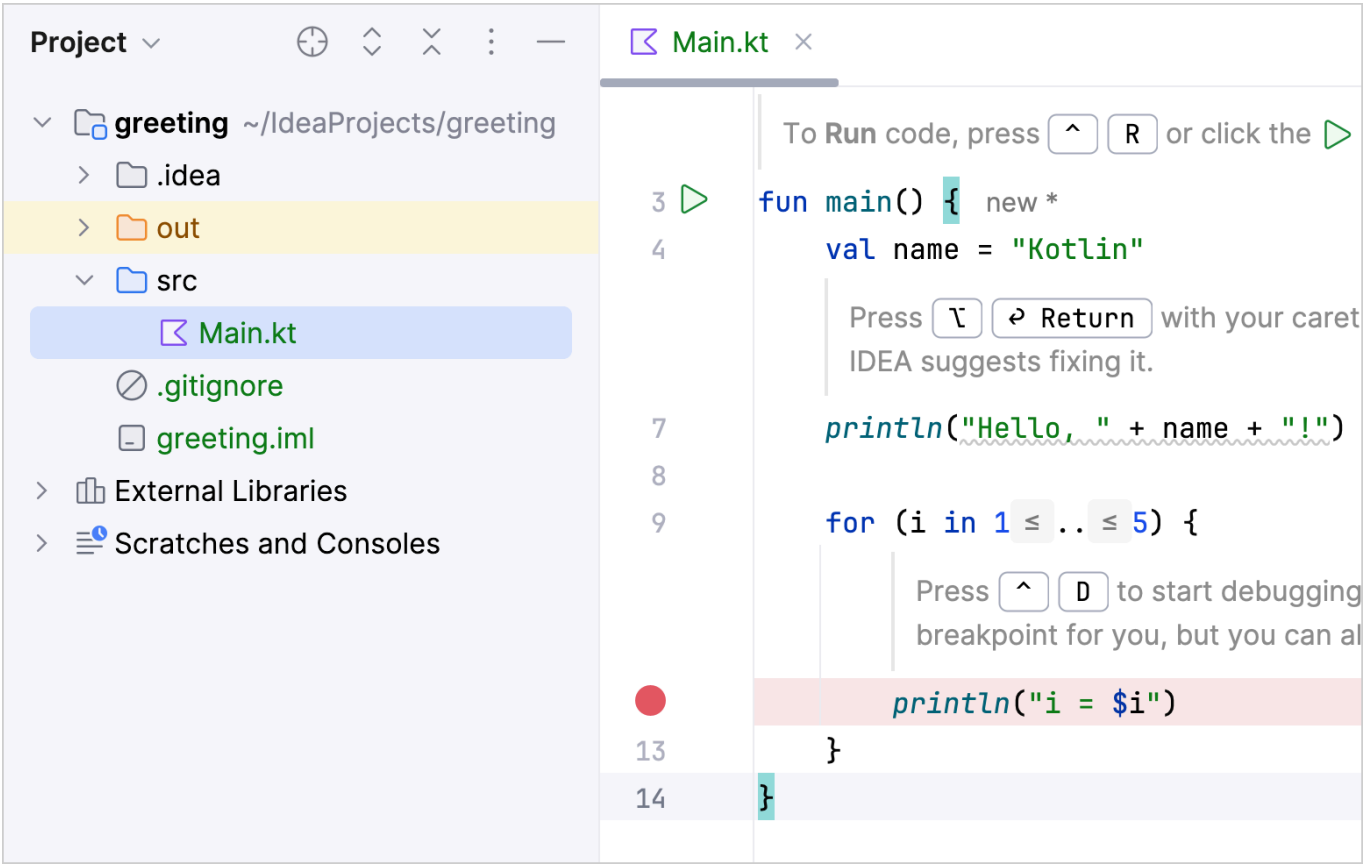
6. Enable the **Add sample code** option to create a file with a sample `"Hello World!"` application.

> You can also enable the **Generate code with onboarding tips** option to add some additional useful comments to your sample code.

7. Click **Create**.

If you chose the Gradle build system, you have in your project a build script file: `build.gradle(.kts)`. It includes the `kotlin("jvm")` plugin and dependencies required for your console application. Make sure that you use the latest version of the plugin:

Kotlin



```
plugins {
    kotlin("jvm") version "2.4.20"
    application
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.jvm' version '2.4.20'
    id 'application'
}
```

Create an application

1. Open the `Main.kt` file in `src/main/kotlin`.
   The `src` directory contains Kotlin source files and resources. The `Main.kt` file contains sample code that will print `Hello, Kotlin!` as well as several lines with values of the cycle iterator.

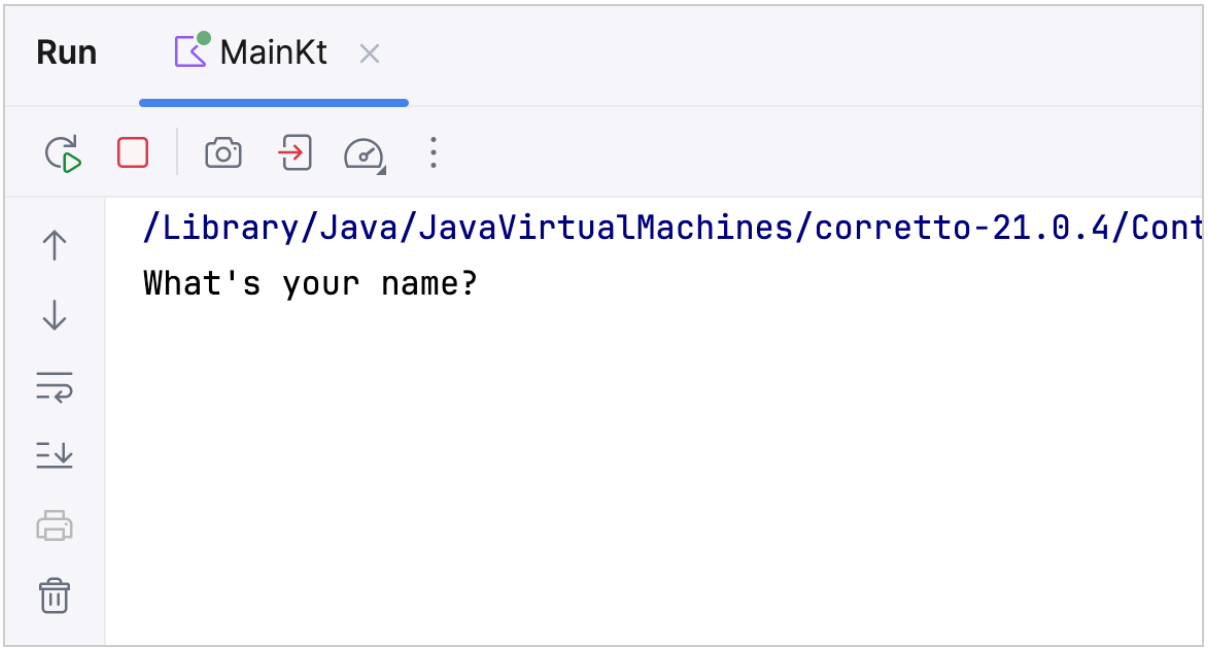
Main.kt with main fun

2. Modify the code so that it requests your name and says `Hello` to you:

   - Create an input prompt and assign to the `name` variable the value returned by the `readln()` function.
   - Let's use a string template instead of concatenation by adding a dollar sign `$` before the variable name directly in the text output like this – `$name`.

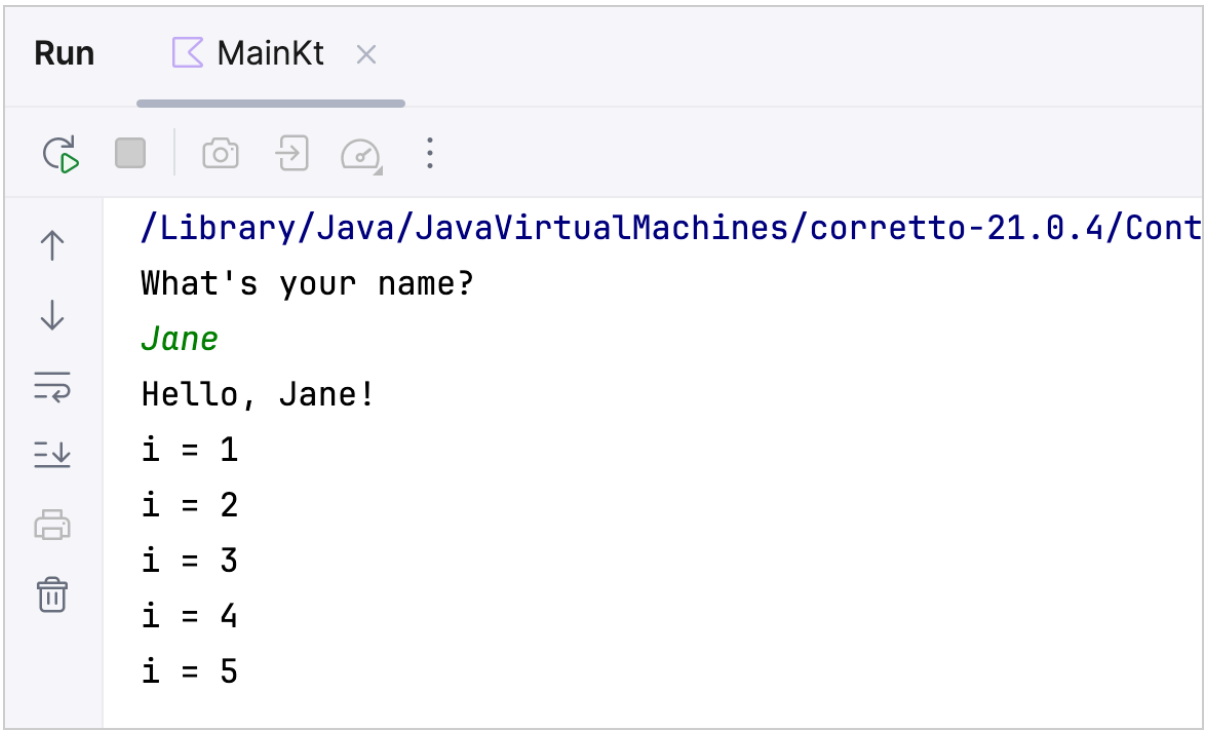
```
fun main() {
    println("What's your name?")
    val name = readln()
    println("Hello, $name!")

    // ...
}
```



Run the application

Now the application is ready to run. The easiest way to do this is to click the green **Run** icon in the gutter and select **Run 'MainKt'**.



Running a console app

You can see the result in the **Run** tool window.

Kotlin run output

Enter your name and accept the greetings from your application!

Kotlin run output

Congratulations! You have just run your first Kotlin application.

What's next?

Once you've created this application, you can start to dive deeper into Kotlin syntax:

- Take the Kotlin tour
- Install the JetBrains Academy plugin for IDEA and complete exercises from the Kotlin Koans course

Kotlin compiler options

Each release of Kotlin includes compilers for the supported targets: JVM, JavaScript, and native binaries for supported platforms.

These compilers are used by:

- The IDE, when you click the **Compile** or **Run** button for your Kotlin project.
- Gradle, when you call `gradle build` in a console or in the IDE.
- Maven, when you call `mvn compile` or `mvn test-compile` in a console or in the IDE.

You can also run Kotlin compilers manually from the command line as described in the Working with command-line compiler tutorial.

Compiler options

Kotlin compilers have a number of options for tailoring the compiling process. Compiler options for different targets are listed on this page together with a description of each one.

There are several ways to set the compiler options and their values (*compiler arguments*):

- In IntelliJ IDEA, write in the compiler arguments in the **Additional command line parameters** text box in **Settings/Preferences** | **Build, Execution, Deployment** | **Compiler** | **Kotlin Compiler**.
- If you're using Gradle, specify the compiler arguments in the `compilerOptions` property of the Kotlin compilation task. For details, see Gradle compiler options.
- If you're using Maven, specify the compiler arguments in the `<configuration>` element of the Maven plugin node. For details, see Maven.
- If you run a command-line compiler, add the compiler arguments directly to the utility call or write them into an argfile.

  For example:

  ```
  $ kotlinc hello.kt -include-runtime -d hello.jar
  ```

  On Windows, when you pass compiler arguments that contain delimiter characters (whitespace, `=`, `;`, `,`), surround these arguments with double quotes (`"`).

  ```
  $ kotlinc.bat hello.kt -include-runtime -d "My Folder\hello.jar"
  ```

Schema for compiler options

A common schema for all compiler options is published under `org.jetbrains.kotlin:kotlin-compiler-arguments-description` as a JAR artifact. This artifact includes both a code representation and a JSON equivalent of all compiler option descriptions (for non-Kotlin consumers). As well as metadata, such as the version in which each option was introduced or stabilized.

Common options

The following options are common for all Kotlin compilers.

-api-version *version*

Set the API version to control which Kotlin APIs your code can use at runtime. For example, if you use Kotlin compiler version 2.4.0 with `-api-version=2.1`, your code remains compatible with Kotlin standard library 2.1.0.

You can't set the `-api-version` value higher than the `-language-version` value.

In most cases, the API version and language version should be the same. One exception is when you develop a library for consumers who must run an older version of the Kotlin standard library. In that case, set an older API version to avoid accidentally using APIs that aren't available to those consumers.

For more information about how the API version affects compatibility, see Backward compatibility guidelines for library authors.

-help (-h)

Display usage information and exit. Only standard options are shown. To show advanced options, use `-X`.

-kotlin-home *path*

Specify a custom path to the Kotlin compiler used for the discovery of runtime libraries.

-language-version *version*

Set the language version to control which Kotlin language features are available during compilation.

For example, if you want to benefit from new compilation performance improvements without changing compiler behavior, you can use a new compiler version with an older language version. With an older language version, you can't use newer language features, but you also don't see new errors and deprecations introduced after that version. This approach is especially useful for library authors who need to preserve compatibility with older Kotlin versions. For more information, see Backward compatibility guidelines for library authors.

You can configure one of the latest three stable versions of Kotlin as the language version. For example, Kotlin 2.5.0 supports language versions as old as 2.2.

If you use an older language version, you also need to use an older API version. For more information, see -api-version version .

> Technically, you can configure a newer language version to try upcoming language features before they are stabilized. However, it's best to enable individual features by following their dedicated instructions.

-opt-in *annotation*

Enable usages of API that requires opt-in with a requirement annotation with the given fully qualified name.

-P plugin:pluginId:optionName=value

Pass an option to a Kotlin compiler plugin. Core plugins and their options are listed in the Core compiler plugins section of the documentation.

-progressive

Enable the progressive mode for the compiler.

In the progressive mode, deprecations and bug fixes for unstable code take effect immediately, instead of going through a graceful migration cycle. Code written in the progressive mode is backwards compatible; however, code written in a non-progressive mode may cause compilation errors in the progressive mode.

-script

Evaluate a Kotlin script file. When called with this option, the compiler executes the first Kotlin script (`*.kts`) file among the given arguments.

-verbose

Enable verbose logging output which includes details of the compilation process.

-version

Display the compiler version.

Experimental

-X

Display information about the advanced options and exit. These options are currently unstable: their names and behavior may be changed without notice.

Experimental

Kotlin contract options

The following options enable experimental Kotlin contract features.

-Xallow-contracts-on-more-functions

Enables contracts in additional declarations, including property accessors, specific operator functions, and type assertions on generic types.

-Xallow-condition-implies-returns-contracts

Allows using the `returnsNotNull()` function in contracts to assume a non-null return value for specified conditions.

-Xallow-holdsin-contract

Allows using the `holdsIn` keyword in contracts to assume that a boolean condition is `true` inside a lambda.

-Xallow-returns-result-of

Allows using the `returnsResultOf()` contract so that the unused return value checker can distinguish between results that can be ignored and meaningful results from higher-order functions.

Experimental

-Xallow-reified-type-in-catch

Enables support for reified `Throwable` type parameters in `catch` clauses of `inline` functions.

Experimental

-Xcollection-literals

Enables support for collection literals with brackets syntax `[]`.

Experimental

-Xcompiler-plugin-order={plugin.before>plugin.after}

Configure the running order of compiler plugins. The compiler runs `plugin.before` first, and then `plugin.after`:

You can define multiple ordering rules for three or more plugins. For example:

```
kotlinc -Xcompiler-plugin-order=plugin.first>plugin.middle
kotlinc -Xcompiler-plugin-order=plugin.middle>plugin.last
```

This results in the following running order:

1. `plugin.first`
2. `plugin.middle`
3. `plugin.last`

If a compiler plugin isn't present, the corresponding rule is ignored.

You can configure the following plugins by their IDs:

Compiler plugin	Plugin ID
`all-open`, `kotlin-spring`	`org.jetbrains.kotlin.allopen`
AtomicFU	`org.jetbrains.kotlinx.atomicfu`
Compose	`androidx.compose.compiler.plugins.kotlin`
`js-plain-objects`	`org.jetbrains.kotlinx.jspo`
`jvm-abi-gen`	`org.jetbrains.kotlin.jvm.abi`
kapt	`org.jetbrains.kotlin.kapt3`
Lombok	`org.jetbrains.kotlin.lombok`
`no-arg`, `kotlin-jpa`	`org.jetbrains.kotlin.noarg`
Parcelize	`org.jetbrains.kotlin.parcelize`
Power-assert	`org.jetbrains.kotlin.powerassert`
SAM with receiver	`org.jetbrains.kotlin.samWithReceiver`
Serialization	`org.jetbrains.kotlinx.serialization`

This running order controls only the backend of compiler plugins and not the frontend.

Experimental

-Xdata-flow-based-exhaustiveness

Enables data-flow–based exhaustiveness checks for `when` expressions.

Experimental

-Xexplicit-context-arguments

Enables explicit context arguments for context parameters.

This lets you resolve overload ambiguity by passing context arguments at the call site.

Experimental

-Xklib-ir-inliner

Configure whether intra-module inlining is enabled for Kotlin/Native, Kotlin/JS, and Kotlin/Wasm. By default, it's enabled.

The option supports the following modes:

- `disabled`: disables intra-module inlining for Kotlin/Native, Kotlin/JS, and Kotlin/Wasm.
- `full`: enables cross-module inlining.

Experimental

-Xintrinsic-const-evaluation

Enables improved compile-time constants.

Experimental

-Xname-based-destructuring

Configure how the compiler interprets destructuring declarations based on property names.

The option supports the following modes:

- `only-syntax`: enables the explicit form of name-based destructuring without changing the behavior of existing destructuring declarations.
- `name-mismatch`: reports warnings when position-based destructuring in data classes uses variable names that don't match the property names.
- `complete`: enables short-form name-based destructuring with parentheses and continues supporting position-based destructuring with square bracket syntax.

Experimental

-Xphases-to-dump-before

Set to `ExternalPackageParentPatcherLowering` to create a dump file after the IR lowering compilation stage. Configure the output directory for the Kotlin/JVM with the `-Xdump-directory` compiler option.

Experimental

-Xrepl

Activates the Kotlin REPL.

```
kotlinc -Xrepl
```

Experimental

-Xreturn-value-checker

Configure how the compiler reports ignored results:

- `disable` : disables the unused return value checker (default).
- `check` : enables the checker and reports warnings for ignored results from marked functions.
- `full` : enables the checker, treats all functions in your project as marked, and reports warnings for ignored results.

Warning management

-nowarn

Suppress all warnings during compilation.

-Werror

Treat all warnings as compilation errors.

-Wextra

Enable additional declaration, expression, and type compiler checks that emit warnings if true.

Experimental

-Xrender-internal-diagnostic-names

Prints internal diagnostic names alongside warnings. This is useful for identifying the `DIAGNOSTIC_NAME` configured for the `-Xwarning-level` option.

Experimental

-Xwarning-level

Configure the severity level of specific compiler warnings:

```
kotlinc -Xwarning-level=DIAGNOSTIC_NAME:(error|warning|disabled)
```

- `error` : raises only the specified warning to an error.
- `warning` : emits a warning for the specified diagnostic and is enabled by default.
- `disabled` : suppresses only the specified warning module-wide.

You can adjust warning reporting in your project by combining module-wide rules with specific ones:

Command	Description
`-nowarn -Xwarning-level=DIAGNOSTIC_NAME:warning`	Suppress all warnings except for the specified ones.

Command	Description
`-Werror -Xwarning-level=DIAGNOSTIC_NAME:warning`	Raise all warnings to errors except for the specified ones.
`-Wextra -Xwarning-level=DIAGNOSTIC_NAME:disabled`	Enable all additional checks except for the specified ones.

If you have many warnings to exclude from the general rules, you can list them in a separate file using `@argfile`.

You can use `-Xrender-internal-diagnostic-names` to discover the `DIAGNOSTIC_NAME`.

@argfile

Read the compiler options from the given file. Such a file can contain compiler options with values and paths to the source files. Options and paths should be separated by whitespaces. For example:

```
-include-runtime -d hello.jar hello.kt
```

To pass values that contain whitespaces, surround them with single (') or double (") quotes. If a value contains quotation marks in it, escape them with a backslash (\).

```
-include-runtime -d 'My folder'
```

You can also pass multiple argument files, for example, to separate compiler options from source files.

```
$ kotlinc @compiler.options @classes
```

If the files reside in locations different from the current directory, use relative paths.

```
$ kotlinc @options/compiler.options hello.kt
```

Kotlin/JVM compiler options

The Kotlin compiler for JVM compiles Kotlin source files into Java class files. The command-line tools for Kotlin to JVM compilation are `kotlinc` and `kotlinc-jvm`. You can also use them for executing Kotlin script files.

In addition to the common options, Kotlin/JVM compiler has the options listed below.

-classpath *path* (-cp *path*)

Search for class files in the specified paths. Separate elements of the classpath with system path separators (**;** on Windows, **:** on macOS/Linux). The classpath can contain file and directory paths, ZIP, or JAR files.

-d *path*

Place the generated class files into the specified location. The location can be a directory, a ZIP, or a JAR file.

-include-runtime

Include the Kotlin runtime into the resulting JAR file. Makes the resulting archive runnable on any Java-enabled environment.

-jdk-home *path*

Use a custom JDK home directory to include into the classpath if it differs from the default `JAVA_HOME`.

Experimental

-Xjdk-release=version

Specify the target version of the generated JVM bytecode. Limit the API of the JDK in the classpath to the specified Java version. Automatically sets `-jvm-target version`. Possible values are `1.8`, `9`, `10`, ..., `26`.

> This option is not guaranteed to be effective for each JDK distribution.

-jvm-default *mode*

Control how functions declared in interfaces are compiled to default methods on the JVM.

Mode	Description
`enable`	Generates default implementations in interfaces and includes bridge functions in subclasses and `DefaultImpls` classes. (Default)
`no-compatibility`	Generates only default implementations in interfaces, skipping compatibility bridges and `DefaultImpls` classes.
`disable`	Generates only compatibility bridges and `DefaultImpls` classes, skipping default methods.

-jvm-target *version*

Specify the target version of the generated JVM bytecode. Possible values are `1.8`, `9`, `10`, ..., `26`. The default value is `1.8`.

-java-parameters

Generate metadata for Java 1.8 reflection on method parameters.

-module-name *name* (JVM)

Set a custom name for the generated `.kotlin_module` file.

-no-jdk

Don't automatically include the Java runtime into the classpath.

-no-reflect

Don't automatically include the Kotlin reflection (`kotlin-reflect.jar`) into the classpath.

-no-stdlib (JVM)

Don't automatically include the Kotlin/JVM stdlib (`kotlin-stdlib.jar`) and Kotlin reflection (`kotlin-reflect.jar`) into the classpath.

-script-templates *classnames[,]*

Script definition template classes. Use fully qualified class names and separate them with commas (,).

Experimental

-Xdump-directory

Configure the dump file directory for the -Xphases-to-dump-before` compiler option.

Experimental

-Xjvm-expose-boxed

Generate boxed versions of all inline value classes in the module, along with boxed variants of functions that use them, making both accessible from Java. For more information, see Inline value classes in the guide to calling Kotlin from Java.

Experimental

-Xnullability-annotations

Configure how the Kotlin compiler interprets nullability annotations from specific Java packages.

For the full list of supported annotations and configuration options, see Nullability annotations.

Kotlin/JS compiler options

The Kotlin compiler for JS compiles Kotlin source files into JavaScript code. The command-line tool for Kotlin to JS compilation is `kotlinc-js` .

In addition to the common options, Kotlin/JS compiler has the options listed below.

-libraries *path*

Paths to Kotlin libraries with `.meta.js` and `.kjsm` files, separated by the system path separator.

-main *{call|noCall}*

Define whether the `main` function should be called upon execution.

-meta-info

Generate `.meta.js` and `.kjsm` files with metadata. Use this option when creating a JS library.

-module-kind {umd|commonjs|amd|plain}

The kind of JS module generated by the compiler:

- `umd` - a Universal Module Definition module
- `commonjs` - a CommonJS module
- `amd` - an Asynchronous Module Definition module
- `plain` - a plain JS module

To learn more about the different kinds of JS modules and the distinctions between them, see this article.

-no-stdlib (JS)

Don't automatically include the default Kotlin/JS stdlib into the compilation dependencies.

-output *filepath*

Set the destination file for the compilation result. The value must be a path to a `.js` file including its name.

-output-postfix *filepath*

Add the content of the specified file to the end of the output file.

-output-prefix *filepath*

Add the content of the specified file to the beginning of the output file.

-source-map

Generate the source map.

-source-map-base-dirs *path*

Use the specified paths as base directories. Base directories are used for calculating relative paths in the source map.

-source-map-embed-sources *{always|never|inlining}*

Embed source files into the source map.

-source-map-names-policy *{simple-names|fully-qualified-names|no}*

Add variable and function names that you declared in Kotlin code into the source map.

Setting	Description	Example output
`simple-names`	Variable names and simple function names are added. (Default)	`main`

Setting	Description	Example output
`fully-qualified-names`	Variable names and fully qualified function names are added.	`com.example.kjs.playground.main`
`no`	No variable or function names are added.	N/A

-source-map-prefix

Add the specified prefix to paths in the source map.

-target {es5|es2015}

Generate JS files for the specified ECMA version.

Experimental

-Xenable-implementing-interfaces-from-typescript

Allow implementing Kotlin interfaces exported with the `@JsExport` annotation from JavaScript/TypeScript.

Experimental

-Xes-long-as-bigint

Enable support for the JavaScript `BigInt` type to represent Kotlin `Long` values when compiling to modern JavaScript (ES2020).

Experimental

-Xsuspend-lambda-exporting

Allow exporting suspending lambda expressions declared in `@JsExport` declarations as JavaScript `async` functions.

Kotlin/Native compiler options

Kotlin/Native compiler compiles Kotlin source files into native binaries for the supported platforms. The command-line tool for Kotlin/Native compilation is `kotlinc-native`.

In addition to the common options, Kotlin/Native compiler has the options listed below.

-enable-assertions (-ea)

Enable runtime assertions in the generated code.

-entry *name* (-e *name*)

Specify the qualified entry point name.

-g

Enable emitting debug information. This option lowers the optimization level and should not be combined with the `-opt` option.

-generate-test-runner (-tr)

Produce an application for running unit tests from the project.

-generate-no-exit-test-runner (-trn)

Produce an application for running unit tests without an explicit process exit.

-include-binary *path* (-ib *path*)

Pack external binary within the generated klib file.

-library *path* (-l *path*)

Link with the library. To learn about using libraries in Kotlin/native projects, see Kotlin/Native libraries.

-library-version *version* (-lv *version*)

Set the library version.

-linker-option

Pass an argument to the linker during binary building. This can be used for linking against some native library.

-linker-options *args*

Pass multiple arguments to the linker during binary building. Separate arguments with whitespaces.

-list-targets

List the available hardware targets.

-manifest *path*

Provide a manifest addend file.

-module-name *name* (Native)

Specify a name for the compilation module. This option can also be used to specify a name prefix for the declarations exported to Objective-C: How do I specify a custom Objective-C prefix/name for my Kotlin framework?

-native-library *path* (-nl *path*)

Include the native bitcode library.

-no-default-libs

Disable linking user code with the prebuilt platform libraries distributed with the compiler.

-nomain

Assume the `main` entry point to be provided by external libraries.

-nopack

Don't pack the library into a klib file.

-nostdlib

Don't link with stdlib.

-opt

Enable compilation optimizations and produce a binary with better runtime performance. It's not recommended to combine it with the `-g` option, which lowers the optimization level.

-output *name* (-o *name*)

Set the name for the output file.

-produce *output* (-p *output*)

Specify output file kind:

- `program`
- `static`
- `dynamic`
- `framework`
- `library`
- `bitcode`

-repo *path* (-r *path*)

Library search path. For more information, see Library search sequence.

-target *target*

Set the hardware target. To see the list of available targets, use the `-list-targets` option.

Experimental

-Xccall-mode

Enable the new interoperability mode for C or Objective-C libraries imported via cinterop.

Experimental

-Xoverride-konan-properties=min.version.*

Configure lower supported versions of Apple targets than the Kotlin defaults. For example:

```
kotlinc -Xoverride-konan-properties=minVersion.ios=14.0
kotlinc -Xoverride-konan-properties=minVersion.macos=11.0
kotlinc -Xoverride-konan-properties=minVersion.tvos=14.0
kotlinc -Xoverride-konan-properties=minVersion.watchos=7.0
```

Compiler execution strategy

The *Kotlin compiler execution strategy* defines where the Kotlin compiler runs. Build tools such as Gradle or Maven configure the strategy.

There are two compiler execution strategies:

Strategy	Where the Kotlin compiler runs	Other characteristics and notes
Kotlin daemon	Inside its own daemon process	*The default and fastest strategy* in Gradle and Maven. The daemon process can be shared between different build system processes and multiple parallel compilations.
In process	Inside the build tool's process	The simplest strategy from the perspective of memory management, but it's less isolated from other logic running in the same process because it shares state, such as JVM system properties.

Configure in Gradle

You can define the Kotlin compiler execution strategy using one of the following properties:

- The `kotlin.compiler.execution.strategy` Gradle property.
- The `compilerExecutionStrategy` compile task property.

Use the Gradle property

The possible values for the `kotlin.compiler.execution.strategy` property are:

- `daemon` (default)
- `in-process`

Set the `kotlin.compiler.execution.strategy` property in `gradle.properties`:

```
kotlin.compiler.execution.strategy=in-process
```

Use the compile task property

The `compilerExecutionStrategy` task property takes priority over the `kotlin.compiler.execution.strategy` Gradle property.

The possible values for the `compilerExecutionStrategy` task property are:

- `DAEMON` (default)
- `IN_PROCESS`

Set the `compilerExecutionStrategy` task property in your build scripts:

Kotlin

```
import org.jetbrains.kotlin.gradle.tasks.CompileUsingKotlinDaemon
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilerExecutionStrategy

// ...

tasks.withType<CompileUsingKotlinDaemon>().configureEach {
    compilerExecutionStrategy.set(KotlinCompilerExecutionStrategy.IN_PROCESS)
}
```

Groovy

```
import org.jetbrains.kotlin.gradle.tasks.CompileUsingKotlinDaemon
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilerExecutionStrategy

// ...

tasks.withType(CompileUsingKotlinDaemon)
        .configureEach {
            compilerExecutionStrategy = KotlinCompilerExecutionStrategy.IN_PROCESS
        }
```

Fallback strategy

If communication with the Kotlin daemon fails, the compiler falls back to the "In process" strategy.

When this fallback happens, Gradle prints the following warning in the build output:

```
Failed to compile with Kotlin daemon: java.lang.RuntimeException: Could not connect to Kotlin compile
daemon
[exception stacktrace]
Using fallback strategy: Compile without Kotlin daemon
Try ./gradlew --stop if this issue persists.
```

A silent fallback can consume a lot of system resources or lead to non-deterministic builds. For more information, see this YouTrack issue.

To prevent fallback, use the `kotlin.daemon.useFallbackStrategy` Gradle property. The default value is `true`. When set to `false`, builds fail if there are problems with the daemon's startup or communication. Declare this property in `gradle.properties`:

```
kotlin.daemon.useFallbackStrategy=false
```

There is also a `useDaemonFallbackStrategy` property in Kotlin compile tasks. If you use both properties, the `useDaemonFallbackStrategy` property takes priority.

Kotlin

```
tasks {
    compileKotlin {
        useDaemonFallbackStrategy.set(false)
    }
}
```

Groovy

```
tasks.named("compileKotlin").configure {
    useDaemonFallbackStrategy = false
}
```

If there is not enough memory to run the compilation, the logs show a related message.

Configure in Maven

By default, Maven uses the Kotlin daemon compiler execution strategy. To switch to the "in process" strategy, set the following property in your `pom.xml` file:

```
<properties>
    <kotlin.compiler.daemon>false</kotlin.compiler.daemon>
</properties>
```

Compiler plugins

Compiler plugins hook into the compilation process to analyze or change code while it's being compiled, without modifying the compiler itself. For example, they can annotate code or generate new code to make it compatible with other frameworks or APIs.

This page explains the Kotlin compiler plugins available to you and what you can do if none of them suits your use case.

The Kotlin team maintains the following compiler plugins:

Plugin	Description
All-open	Automatically makes annotated classes and their members `open` so frameworks can extend them at runtime.
AtomicFU	Transforms atomic operations into efficient, platform-specific implementations for lock-free concurrency.
DataFrame	Generates typed APIs that let you work with a `DataFrame` in a safe, Kotlin-friendly way.

Plugin	Description
`jvm-abi-gen`	Generates Application Binary Interface (ABI) JARs.
`js-plain-objects`	Exposes Kotlin classes as plain JavaScript objects to improve interop with JS tooling and libraries.
kapt	Runs Java annotation processors on Kotlin code and generates additional source files.
Lombok	Enables Kotlin code to understand and use code generated by Lombok annotations in Java sources.
`no-arg`	Generates no-argument constructors for annotated classes to support frameworks that require them.
Power-assert	Enhances assertion failures by showing detailed values for each part of an expression.
SAM with receiver	Allows SAM interfaces to use lambdas with receivers for a more DSL-like syntax.
Serialization	Generates code that serializes and deserializes Kotlin objects without reflection.

The Android team at Google maintains:

Plugin	Description
Compose compiler Gradle plugin	Integrates the Compose compiler with Gradle to enable declarative UI features and Compose-specific optimizations.
Parcelize plugin	Generates `Parcelable` implementations automatically so you can pass Kotlin objects between Android components.

If you need to adapt the compilation process in a way that these plugins don't cover, first check whether you can use the Kotlin Symbol Processing (KSP) API or an external linter such as Android lint. You can browse our Kotlin Slack or reach out and ask for advice about your use case.

If you *still* can't find what you need, you can create a custom compiler plugin. Use this approach only as a last resort, because the Kotlin compiler plugin API is **unstable**. If you create a custom compiler plugin, you need to invest significant ongoing effort to maintain it, since each new compiler release introduces breaking changes.

All-open compiler plugin

Kotlin has classes and their members `final` by default, which makes it inconvenient to use frameworks and libraries such as Spring AOP that require classes to be `open`. The `all-open` compiler plugin adapts Kotlin to the requirements of those frameworks and makes classes annotated with a specific annotation and their members open without the explicit `open` keyword.

For instance, when you use Spring, you don't need all the classes to be open, but only classes annotated with specific annotations like `@Configuration` or `@Service`. The `all-open` plugin allows you to specify such annotations.

Kotlin provides `all-open` plugin support both for Gradle and Maven with the complete IDE integration.

For Spring, you can use the `kotlin-spring` compiler plugin.

Gradle

Add the plugin in your `build.gradle(.kts)` file:

Kotlin

```
plugins {
    kotlin("plugin.allopen") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.plugin.allopen" version "2.4.20"
}
```

Then specify the list of annotations that will make classes open:

Kotlin

```
allOpen {
    annotation("com.my.Annotation")
    // annotations("com.another.Annotation", "com.third.Annotation")
}
```

Groovy

```
allOpen {
    annotation("com.my.Annotation")
    // annotations("com.another.Annotation", "com.third.Annotation")
}
```

If the class (or any of its superclasses) is annotated with `com.my.Annotation`, the class itself and all its members will become open.

It also works with meta-annotations:

```
@com.my.Annotation
annotation class MyFrameworkAnnotation

@MyFrameworkAnnotation
class MyClass // will be all-open
```

`MyFrameworkAnnotation` is annotated with the all-open meta-annotation `com.my.Annotation`, so it becomes an all-open annotation as well.

Maven

Add the plugin in your `pom.xml` file:

```
<plugin>
    <artifactId>kotlin-maven-plugin</artifactId>
    <groupId>org.jetbrains.kotlin</groupId>
    <version>${kotlin.version}</version>

    <configuration>
        <compilerPlugins>
            <!-- Or "spring" for the Spring support -->
            <plugin>all-open</plugin>
        </compilerPlugins>

        <pluginOptions>
            <!-- Each annotation is placed on its own line -->
            <option>all-open:annotation=com.my.Annotation</option>
            <option>all-open:annotation=com.their.AnotherAnnotation</option>
        </pluginOptions>
    </configuration>

    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-allopen</artifactId>
            <version>${kotlin.version}</version>
        </dependency>
    </dependencies>
</plugin>
```

Please refer to the Gradle section for the detailed information about how all-open annotations work.

Spring support

If you use Spring, you can enable the `kotlin-spring` compiler plugin instead of specifying Spring annotations manually. The `kotlin-spring` is a wrapper on top of `all-open`, and it behaves exactly the same way.

Add the `spring` plugin in your `build.gradle(.kts)` file:

Kotlin

```
plugins {
    id("org.jetbrains.kotlin.plugin.spring") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.plugin.spring" version "2.4.20"
}
```

In Maven, the `spring` plugin is provided by the `kotlin-maven-allopen` plugin dependency, so to enable it in your `pom.xml` file:

```
<compilerPlugins>
    <plugin>spring</plugin>
</compilerPlugins>

<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlin</groupId>
        <artifactId>kotlin-maven-allopen</artifactId>
        <version>${kotlin.version}</version>
    </dependency>
</dependencies>
```

The plugin specifies the following annotations:

- `@Component`
- `@Async`
- `@Transactional`
- `@Cacheable`
- `@SpringBootTest`

Thanks to meta-annotations support, classes annotated with `@Configuration`, `@Controller`, `@RestController`, `@Service` or `@Repository` are automatically opened since these annotations are meta-annotated with `@Component`.

Of course, you can use both `kotlin-allopen` and `kotlin-spring` in the same project.

If you generate the project template by the start.spring.io service, the `kotlin-spring` plugin will be enabled by default.

Command-line compiler

All-open compiler plugin JAR is available in the binary distribution of the Kotlin compiler. You can attach the plugin by providing the path to its JAR file using the `-Xplugin` kotlinc option:

```
-Xplugin=$KOTLIN_HOME/lib/allopen-compiler-plugin.jar
```

You can specify all-open annotations directly, using the `annotation` plugin option, or enable the *preset*:

```
# The plugin option format is: "-P plugin:<plugin id>:<key>=<value>".
# Options can be repeated.

-P plugin:org.jetbrains.kotlin.allopen:annotation=com.my.Annotation
-P plugin:org.jetbrains.kotlin.allopen:preset=spring
```

Presets that available for the `all-open` plugin are: `spring`, `micronaut`, and `quarkus`.

kapt compiler plugin

The kapt compiler plugin allows you to use existing Java annotation processors in Kotlin and works with both Maven and Gradle. It generates stub files from Kotlin source code and then runs the Java annotation processors on those stubs.

This enables Java-based annotation processing in your Kotlin projects for libraries like MapStruct and Data Binding.

> kapt is not supported in the IntelliJ build system. To re-run annotation processing in IntelliJ IDEA, launch the build from the **Maven** tool window.

Set up the plugin

You can configure the kapt plugin for Gradle, Maven, or use it from the command line.

Gradle

To use kapt in Gradle, follow these steps:

1. Apply the `kapt` Gradle plugin in your build script file `build.gradle(.kts)`:

Kotlin

```
plugins {
    kotlin("kapt") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.kapt" version "2.4.20"
}
```

2. Add the respective dependencies using the `kapt` configuration in the `dependencies {}` block:

Kotlin

```
dependencies {
    kapt("groupId:artifactId:version")
}
```

Groovy

```
dependencies {
    kapt 'groupId:artifactId:version'
}
```

3. If you previously used the Android support for annotation processors, replace usages of the `annotationProcessor` configuration with `kapt`. If your project contains Java classes, the kapt plugin processes them as well.

   If you use annotation processors for your `androidTest` or `test` sources, the respective `kapt` configurations are named `kaptAndroidTest` and `kaptTest`. Note that `kaptAndroidTest` and `kaptTest` extend `kapt`, so you can provide the `kapt` dependency, and it will be available both for production sources and tests.

Maven

You can set up kapt using either the `<extensions>` option to simplify setup or manually to get full control over kapt's execution.

Automatic configuration

You can simplify kapt configuration by enabling the `<extensions>` option for the Kotlin Maven plugin. In this case, you don't need to manually set up kapt's `<execution>` section with goals or source directories.

To automatically configure kapt, set the `<extensions>` option to `true` for the `kotlin-maven-plugin` in your `pom.xml` build file:

```
<plugin>
    <groupId>org.jetbrains.kotlin</groupId>
    <artifactId>kotlin-maven-plugin</artifactId>
    <version>${kotlin.version}</version>
    <extensions>true</extensions>
    <configuration>
        <annotationProcessorPaths>
            <!-- Specify your annotation processors here -->
            <annotationProcessorPath>
                <groupId>org.mapstruct</groupId>
                <artifactId>mapstruct-processor</artifactId>
                <version>1.6.3</version>
            </annotationProcessorPath>
        </annotationProcessorPaths>
    </configuration>
</plugin>
```

For more information on the `<extensions>` option, see Automatic configuration.

Manual configuration

To manually set up kapt in your Kotlin Maven project, add an execution of the `kapt` goal from `kotlin-maven-plugin` before the `compile` execution:

```
<execution>
    <id>kapt</id>
    <goals>
        <goal>kapt</goal>
    </goals>
    <configuration>
        <sourceDirs>
            <sourceDir>src/main/kotlin</sourceDir>
            <sourceDir>src/main/java</sourceDir>
        </sourceDirs>
        <annotationProcessorPaths>
            <!-- Specify your annotation processors here -->
            <annotationProcessorPath>
                <groupId>org.mapstruct</groupId>
                <artifactId>mapstruct-processor</artifactId>
                <version>1.6.3</version>
            </annotationProcessorPath>
        </annotationProcessorPaths>
    </configuration>
</execution>
```

To configure the annotation processing mode, set the `aptMode` option in the `<configuration>` block. For example:

```
<configuration>
   ...
   <aptMode>stubs</aptMode>
</configuration>
```

CLI

kapt is available as a standalone CLI tool in the binary distribution of the Kotlin compiler.

To run kapt from the command line, use:

```
kapt <options> <source files>
```

For example:

```
kapt -Kapt-mode=stubsAndApt \
  -Kapt-sources=build/kapt/sources \
  -Kapt-classes=build/kapt/classes \
  -Kapt-stubs=build/kapt/stubs \
  -Kapt-classpath=lib/ap.jar \
  -Kapt-classpath=lib/anotherAp.jar \
  src/main/kotlin
```

- See the full list of kapt-specific compiler options.
- You can also pass all valid Kotlin compiler options. Run `kotlinc -help` to see them.

Configure annotation processors

kapt provides options to control how annotation processors are discovered, organized, and executed, including managing the processor classpath, inheriting processors from shared configurations, and keeping javac-specific processors active.

For more configuration options, such as passing options to annotation processors and javac, see Annotation processor configuration.

Configure processor classpath and discovery

You can disable the discovery of annotation processors that aren't included in kapt's processor path. This excludes unnecessary annotation processors from the compile classpath.

Gradle

Gradle uses compile avoidance to skip annotation processing during project rebuild, improving incremental build times with kapt. Particularly, annotation processing is skipped when:

- The project's source files are unchanged.
- The changes in dependencies are ABI-compatible. For example, when only function bodies change.

However, compile avoidance can't be used for annotation processors discovered on the compile classpath, since changes in their internal implementation require running the annotation processing tasks, even if the processors' ABI remains unchanged.

That's why we don't recommend using annotation processors from the compile classpath. To exclude these processors from kapt processing, add the `kapt.include.compile.classpath` property to your `gradle.properties` file:

```
# gradle.properties
kapt.include.compile.classpath=false
```

With the option set to `false`, annotation processor dependencies that aren't included in the processor path (the `kapt*` configurations) are excluded from kapt processing.

Maven

To exclude annotation processors that aren't included in the kapt's processor path, set the `includeCompileClasspath` option to `false` in the `<execution>` section of the kapt plugin:

```
<execution>
    <id>kapt</id>
    <goals>
        <goal>kapt</goal>
    </goals>
    <configuration>
        <includeCompileClasspath>false</includeCompileClasspath>
        <sourceDirs>...</sourceDirs>
        <annotationProcessorPaths>...</annotationProcessorPaths>
    </configuration>
</execution>
```

Alternatively, you can use the `kapt.include.compile.classpath` property in the `<properties>` section of your `pom.xml`:

```
<properties>
    <kapt.include.compile.classpath>false</kapt.include.compile.classpath>
</properties>
```

With the option set to `false`, annotation processors that aren't included in the `<annotationProcessorPaths>` section are excluded from kapt processing.

If the `includeCompileClasspath` option isn't set and kapt detects an annotation processor on the compile classpath that isn't explicitly defined in the processor path, you'll see a deprecation warning:

```
[WARNING] Annotation processors discovery from compile classpath is deprecated.
Set 'kapt.include.compile.classpath=false' to disable discovery.
```

To see the list of annotation processors that aren't included on the kapt classpath, run the build with the `--info` log level option.

Inherit annotation processors from superconfigurations

You can define a common set of annotation processors in a separate Gradle configuration as a superconfiguration and extend it further in kapt-specific configurations for your subprojects.

As an example, for a subproject using MapStruct, in your `build.gradle(.kts)` file, use the following configuration:

```
val commonAnnotationProcessors by configurations.creating
configurations.named("kapt") { extendsFrom(commonAnnotationProcessors) }

dependencies {
    implementation("org.mapstruct:mapstruct:1.6.3")
    commonAnnotationProcessors("org.mapstruct:mapstruct-processor:1.6.3")
}
```

In this example, the `commonAnnotationProcessors` Gradle configuration is the common superconfiguration for annotation processing that you want to be used for all your projects. You use the `extendsFrom()` method to add `commonAnnotationProcessors` as a superconfiguration. kapt sees that the `commonAnnotationProcessors` Gradle configuration has a dependency on the MapStruct annotation processor. Therefore, kapt includes the MapStruct annotation processor in its configuration for annotation processing.

Keep Java compiler's annotation processors

By default, kapt runs all annotation processors and disables annotation processing by javac. However, you may need javac to run some annotation processors, such as Lombok.

In the Gradle build file, use the option `keepJavacAnnotationProcessors`:

```
kapt {
    keepJavacAnnotationProcessors = true
}
```

If you use Maven, configure the plugin explicitly. See this example of setting up the Lombok compiler plugin.

Optimize kapt builds

kapt offers several Gradle-specific strategies to reduce annotation processing time, including running tasks in parallel, leveraging the build cache, caching processor classloaders, and using incremental annotation processing.

For more options that affect build behavior, such as error type correction, stub metadata stripping, and compile classpath scanning, see Behavioral options.

Run kapt tasks in parallel

kapt uses the Gradle Worker API to run annotation processing tasks. Using the Worker API lets Gradle run independent annotation processing tasks from a single project in parallel, which in some cases significantly decreases the execution time.

If you set the custom JDK version in the Kotlin Gradle plugin, kapt task workers use only the `processIsolation()` mode.

If you want to provide additional JVM arguments for a kapt worker process, use the input `kaptProcessJvmArgs` of the `KaptWithoutKotlincTask`:

Kotlin

```
tasks.withType<org.jetbrains.kotlin.gradle.internal.KaptWithoutKotlincTask>()
    .configureEach {
        kaptProcessJvmArgs.add("-Xmx512m")
    }
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.internal.KaptWithoutKotlincTask.class)
    .configureEach {
        kaptProcessJvmArgs.add('-Xmx512m')
    }
```

Use Gradle build cache safely

Gradle caches kapt annotation processing tasks by default. However, annotation processors can run arbitrary code. This may result in unnecessary transformations of task inputs into outputs, or accessing and modifying files that Gradle doesn't track.

When annotation processors used in the build can't be properly cached, you can disable caching to prevent false-positive hits for kapt tasks. To do this, use the `useBuildCache` property in the build script:

```
kapt {
    useBuildCache = false
}
```

Experimental

Cache annotation processors' classloaders

Caching for annotation processors' classloaders helps kapt perform faster if you run many Gradle tasks consecutively.

To enable this feature, use the following properties in your `gradle.properties` file:

```
# gradle.properties
#
# Any positive value enables caching
# Use the same value as the number of modules that use kapt
kapt.classloaders.cache.size=5

# Disable for caching to work
kapt.include.compile.classpath=false
```

If you run into any problems with caching for annotation processors, disable caching for them:

```
# Specify annotation processors' full names to disable caching for them
kapt.classloaders.cache.disableForProcessors=[annotation processors full names]
```

If you encounter any issues with the feature, we would appreciate your feedback in YouTrack.

Use incremental annotation processing

With Gradle, kapt supports incremental annotation processing by default so that only the changed files are re-processed.

Currently, incremental annotation processing works only if:

- Incremental compilation is enabled.
- All annotation processors in the build are incremental.

To disable incremental annotation processing, add this line to your `gradle.properties` file:

```
kapt.incremental.apt=false
```

Currently, incremental annotation processing for kapt isn't supported in Maven or the CLI.

Analyze performance

kapt provides built-in diagnostics to help you understand annotation processing performance, including per-processor execution time reports and generated file counts to identify unused processors.

For more diagnostic options, such as file read history for debugging incremental processing and memory leak detection, see Diagnostics and statistics options.

Measure the performance of annotation processors

To get performance statistics on the annotation processors execution, use the `showProcessorStats` option. An example output:

```
Kapt Annotation Processing performance report:
com.example.processor.TestingProcessor: total: 133 ms, init: 36 ms, 2 round(s): 97 ms, 0 ms
com.example.processor.AnotherProcessor: total: 100 ms, init: 6 ms, 1 round(s): 93 ms
```

You can dump this report to a file with the `dumpProcessorStats` option. For example, the following CLI command runs kapt and dumps the statistics to the `ap-perf-report.file` file:

```
kapt -Kapt-mode=stubsAndApt \
  -Kapt-classpath=processor/build/libs/processor.jar \
  -Kapt-dump-processor-stats=ap-perf-report.file \
  sample/src/main/
```

Track the number of generated files

The kapt plugin can report statistics on the number of generated files for each annotation processor.

This helps track whether any unused annotation processors are included in the build. You can use the generated report to find modules that trigger unnecessary annotation processors and update the modules to avoid that.

To enable statistics reporting:

1. In your Gradle build file, set the `showProcessorStats` option to `true`:

   ```
   // build.gradle(.kts)
   kapt {
       showProcessorStats = true
   }
   ```

2. In your `gradle.properties` file, set the `verbose` compiler option to `true`:

   ```
   # gradle.properties
   kapt.verbose=true
   ```

The statistics appear in the logs with the `info` level. You can see the `Annotation processor stats:` line followed by statistics on the execution time of each annotation processor. After these lines, there is the `Generated files report:` line followed by statistics on the number of generated files for each annotation processor. For example:

```
[INFO] Annotation processor stats:
[INFO] org.mapstruct.ap.MappingProcessor: total: 290 ms, init: 1 ms, 3 round(s): 289 ms, 0 ms, 0 ms
[INFO] Generated files report:
[INFO] org.mapstruct.ap.MappingProcessor: total sources: 2, sources per round: 2, 0, 0
```

Currently, tracking the number of generated files with the `showProcessorStats` and `verbose` compiler options isn't supported in Maven or the CLI.

Generate Kotlin sources

kapt can generate Kotlin sources. To do that, write the generated Kotlin source files to the specified directory using `processingEnv.options["kapt.kotlin.generated"]`. Kotlin source files are then compiled together with the main sources.

kapt doesn't support multiple rounds of annotation processing for the generated Kotlin files.

Compiler options

Annotation processor configuration

Option	Description	How to set up
`aptMode`	Controls the execution of kapt workflow stages: • `stubsAndApt` generates stubs and runs annotation processing (default) • `stubs` only generates Java stubs from Kotlin • `apt` only runs annotation processors (assumes stubs already exist)	Gradle: not directly available; Gradle runs stubs and apt as separate tasks Maven: `<aptMode>stubsAndApt</aptMode>` CLI: `-Kapt-mode=stubsAndApt`

`classpath`	Classpath entries where annotation processors are discovered.	Gradle:
		`dependencies { kapt("com.example:processor:1.0") }`
		Maven:
		`<annotationProcessorPaths> <annotationProcessorPath>...</annotationProcessorPath> </annotationProcessorPaths>`
		CLI: `-Kapt-classpath=lib/my-processor.jar`

`processors`	Comma-separated fully qualified class	Gradle:

Option	Description	How to set up

	names of processors to run, bypassing discovery.	`kapt { annotationProcessor("com.example.MyProcessor") }`
		Maven:
		`<annotationProcessors><annotationProcessor>com.example.MyProcessor</annotationProcessor></annotationProcessors>`
		CLI: `-Kapt-processors=com.example.MyProcessor`

`apOption`	Key-value options passed to annotation processors.	Gradle:
		`kapt { arguments { arg("room.schemaLocation", "$projectDir/schemas") } }`
		Maven:
		`<annotationProcessorArgs><annotationProcessorArg>room.schemaLocation=/schemas</annotationProcessorArg></annotationProcessorArgs>`
		CLI: `-Kapt-options:room.schemaLocation=/schemas`

`javacOption`	Key-value options passed to the Java compiler.	Gradle:
		`kapt { javacOptions { option("-source", "11") } }`
		Maven:
		`<javacOptions><javacOption>-source=11</javacOption></javacOptions>`
		CLI: `-Kapt-javac-option:-source=11`

`processIncrementally`	Enables incremental annotation processing; only reprocesses	Gradle: `# gradle.properties kapt.incremental.apt=true` Maven: currently not supported

Option	Description	How to set up
	files affected by changes.	CLI: currently not supported

Output directory options

Option	Description	How to set up
`sources`	Directory where annotation processors generate `.java` source files.	Gradle: set automatically to `build/generated/source/kapt/main` Maven: set automatically to `target/generated-sources/kapt/` CLI: `-Kapt-sources=build/kapt/sources`
`classes`	Directory for `.class` files compiled from generated sources.	Gradle: managed automatically Maven: managed automatically CLI: `-Kapt-classes=build/kapt/classes`
`stubs`	Directory for Java stub files generated from Kotlin sources, used as input to annotation processors.	Gradle: managed automatically Maven: managed automatically CLI: `-Kapt-stubs=build/kapt/stubs`
`incrementalData`	Stores state for incremental builds.	Gradle: managed automatically Maven: currently not supported CLI: currently not supported

Behavioral options

Option	Description	How to set up
`correctErrorTypes`	By default, kapt replaces every unknown type (including types for the generated classes) with `NonExistentClass`. You can enable error type interference in stubs to replace unresolved	Gradle: `kapt { correctErrorTypes = true }` Maven:

Option	Description	How to set up
	error types with types from generated sources. `false` by default	`<correctErrorTypes>true</correctErrorTypes>` CLI: `-Kapt-correct-error-types=true`
`dumpDefaultParameterValues`	Includes default parameter initializers as field values in generated stubs. `false` by default	Gradle: `kapt { dumpDefaultParameterValues = true }` Maven: not available CLI: `-Kapt-dump-default-parameter-values=true`

`mapDiagnosticLocations`	Maps error messages from stub files back to their original Kotlin source locations.
	`false` by default
		Gradle:
		`kapt { mapDiagnosticLocations = true }`
		Maven:
		`<mapDiagnosticLocations>true</mapDiagnosticLocations>`
		CLI: `-Kapt-map-diagnostic-locations=true`

`strict`	Turns stub generation incompatibilities into errors instead of warnings. `false` by default	Gradle: `kapt { strictMode = true }` Maven: not available CLI: `-Kapt-strict=true`
`stripMetadata`	Removes `@kotlin.Metadata` annotations from generated stubs, reducing stub size and hiding Kotlin-specific info from processors. `false` by default	Gradle: `kapt { stripMetadata = true }` Maven: not available CLI: `-Kapt-strip-metadata=true`
`verbose`	Enables verbose kapt logging. `false` by default	Gradle:

Option	Description	How to set up

		`# gradle.properties`
		`kapt.verbose=true`
		
		Maven: currently not supported
		
		CLI: currently not supported

`infoAsWarnings`	Promotes info-level kapt messages to warnings. `false` by default	Gradle: not directly available Maven: currently not supported CLI: currently not supported

`includeCompileClasspath`	Scans the compile classpath for annotation processors. Set to `false` for reproducibility.
	
	`true` by default
		Gradle:
		`kapt {`
		`includeCompileClasspath = false`
		`}`
		
		Maven:
		`<includeCompileClasspath>false</includeCompileClasspath>`
		
		CLI: currently not supported

Diagnostics and statistics options

Option	Description	How to set up

`showProcessorStats`	Prints per-processor execution time to stdout.	Gradle:
		`kapt {`
		`showProcessorStats = true`
		`}`
		
		Maven: not available
		
		CLI: `-Kapt-show-processor-stats=true`

`dumpProcessorStats`	Writes processor timing stats to a file.	Gradle: not available Maven: not available CLI: `-Kapt-dump-processor-stats=build/kapt-stats.txt`

Option	Description	How to set up
`dumpFileReadHistory`	Writes a list of files read by processors to a file, useful for incremental annotation processor debugging.	Gradle: not available Maven: not available CLI: `-Kapt-dump-file-read-history=build/kapt-reads.txt`
`detectMemoryLeaks`	Memory leak detection mode: `none`, `default`, or `paranoid`.	Gradle: `kapt { detectMemoryLeaks = "paranoid" }` Maven: currently not supported CLI: currently not supported

What's next

- Use kapt with the MapStruct annotation processor
- See how to migrate from kapt to KSP

Lombok compiler plugin

The Kotlin Lombok compiler plugin allows the generation and use of Java's Lombok declarations by Kotlin code in the same mixed Java/Kotlin module. If you call such declarations from another module, then you don't need to use this plugin for the compilation of that module.

The Lombok compiler plugin cannot replace Lombok, but it helps Lombok work in mixed Java/Kotlin modules. Thus, you still need to configure Lombok as usual when using this plugin. Learn more about how to configure the Lombok compiler plugin.

Supported annotations

The plugin supports the following annotations:

- `@Getter`, `@Setter`
- `@Builder`, `@SuperBuilder`
- `@NoArgsConstructor`, `@RequiredArgsConstructor`, and `@AllArgsConstructor`
- `@Data`
- `@With`
- `@Value`

We're continuing to work on this plugin. To find out the detailed current state, visit the Lombok compiler plugin's README.

Currently, we don't have plans to support the `@Tolerate` annotation. However, we can consider this if you vote for the @Tolerate issue in YouTrack.

Kotlin compiler ignores Lombok annotations if you use them in Kotlin code.

Gradle

Apply the `kotlin-plugin-lombok` Gradle plugin in the `build.gradle(.kts)` file:

Kotlin

```
plugins {
    kotlin("plugin.lombok") version "2.4.20"
    id("io.freefair.lombok") version "9.5.0"
}
```

Groovy

```
plugins {
    id 'org.jetbrains.kotlin.plugin.lombok' version '2.4.20'
    id 'io.freefair.lombok' version '9.5.0'
}
```

See this test project with examples of the Lombok compiler plugin in use.

Using the Lombok configuration file

If you use a Lombok configuration file `lombok.config`, you need to set the file's path so that the plugin can find it. The path must be relative to the module's directory. For example, add the following code to your `build.gradle(.kts)` file:

Kotlin

```
kotlinLombok {
    lombokConfigurationFile(file("lombok.config"))
}
```

Groovy

```
kotlinLombok {
    lombokConfigurationFile file("lombok.config")
}
```

See this test project with examples of the Lombok compiler plugin and `lombok.config` in use.

Maven

To use the Lombok compiler plugin, add the plugin `lombok` to the `compilerPlugins` section and the dependency `kotlin-maven-lombok` to the `dependencies` section. If you use a Lombok configuration file `lombok.config`, provide a path to it to the plugin in the `pluginOptions`. Add the following lines to the `pom.xml` file:

```
<plugin>
    <groupId>org.jetbrains.kotlin</groupId>
    <artifactId>kotlin-maven-plugin</artifactId>
    <version>${kotlin.version}</version>
    <configuration>
        <compilerPlugins>
            <plugin>lombok</plugin>
        </compilerPlugins>
        <pluginOptions>
            <option>lombok:config=${project.basedir}/lombok.config</option>
        </pluginOptions>
    </configuration>
    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-lombok</artifactId>
            <version>${kotlin.version}</version>
        </dependency>
        <dependency>
            <groupId>org.projectlombok</groupId>
            <artifactId>lombok</artifactId>
            <version>1.18.20</version>
            <scope>provided</scope>
        </dependency>
    </dependencies>
</plugin>
```

See this test project example of the Lombok compiler plugin and `lombok.config` in use.

Using with kapt

By default, the kapt compiler plugin runs all annotation processors and disables annotation processing by javac. To run Lombok along with kapt, set up kapt to keep javac's annotation processors working.

If you use Gradle, add the option to the `build.gradle(.kts)` file:

```
kapt {
    keepJavacAnnotationProcessors = true
}
```

In Maven, use the following settings to launch Lombok with Java's compiler:

```
<plugin>
    <groupId>org.apache.maven.plugins</groupId>
    <artifactId>maven-compiler-plugin</artifactId>
    <version>3.5.1</version>
    <configuration>
        <source>1.8</source>
        <target>1.8</target>
        <annotationProcessorPaths>
            <annotationProcessorPath>
                <groupId>org.projectlombok</groupId>
                <artifactId>lombok</artifactId>
                <version>${lombok.version}</version>
            </annotationProcessorPath>
        </annotationProcessorPaths>
    </configuration>
</plugin>
```

The Lombok compiler plugin works correctly with kapt if annotation processors don't depend on the code generated by Lombok.

Look through the test project examples of kapt and the Lombok compiler plugin in use:

- Using Gradle.
- Using Maven

Command-line compiler

Lombok compiler plugin JAR is available in the binary distribution of the Kotlin compiler. You can attach the plugin by providing the path to its JAR file using the `Xplugin` kotlinc option:

```
-Xplugin=$KOTLIN_HOME/lib/lombok-compiler-plugin.jar
```

If you want to use the `lombok.config` file, replace `<PATH_TO_CONFIG_FILE>` with a path to your `lombok.config`:

```
# The plugin option format is: "-P plugin:<plugin id>:<key>=<value>".
# Options can be repeated.

-P plugin:org.jetbrains.kotlin.lombok:config=<PATH_TO_CONFIG_FILE>
```

No-arg compiler plugin

The *no-arg* compiler plugin generates an additional zero-argument constructor for classes with a specific annotation.

The generated constructor is synthetic, so it can't be directly called from Java or Kotlin, but it can be called using reflection.

This allows the Java Persistence API (JPA) to instantiate a class, although it doesn't have the zero-parameter constructor from Kotlin or Java point of view (see the description of `kotlin-jpa` plugin below).

In your Kotlin file

Add new annotations to mark the code that needs a zero-argument constructor:

```
package com.my

annotation class Annotation
```

Gradle

Add the plugin using Gradle's plugins DSL:

Kotlin

```
plugins {
    kotlin("plugin.noarg") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.plugin.noarg" version "2.4.20"
}
```

Then specify the list of no-arg annotations that must lead to generating a no-arg constructor for the annotated classes:

```
noArg {
    annotation("com.my.Annotation")
}
```

Enable `invokeInitializers` option if you want the plugin to run the initialization logic from the synthetic constructor. By default, it is disabled.

```
noArg {
    invokeInitializers = true
}
```

Maven

```
<plugin>
    <artifactId>kotlin-maven-plugin</artifactId>
    <groupId>org.jetbrains.kotlin</groupId>
    <version>${kotlin.version}</version>

    <configuration>
        <compilerPlugins>
            <!-- Or "jpa" for JPA support -->
            <plugin>no-arg</plugin>
        </compilerPlugins>

        <pluginOptions>
            <option>no-arg:annotation=com.my.Annotation</option>
            <!-- Call instance initializers in the synthetic constructor -->
            <!-- <option>no-arg:invokeInitializers=true</option> -->
        </pluginOptions>
    </configuration>

    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-noarg</artifactId>
            <version>${kotlin.version}</version>
        </dependency>
    </dependencies>
</plugin>
```

JPA support

As with the `kotlin-spring` plugin wrapped on top of `all-open`, `kotlin-jpa` is wrapped on top of `no-arg`. The plugin specifies `@Entity`, `@Embeddable`, and `@MappedSuperclass` *no-arg* annotations automatically.

Add the plugin using the Gradle plugins DSL:

Kotlin

```
plugins {
    kotlin("plugin.jpa") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.plugin.jpa" version "2.4.20"
}
```

In Maven, enable the `jpa` plugin:

```
<compilerPlugins>
    <plugin>jpa</plugin>
</compilerPlugins>
```

Command-line compiler

Add the plugin JAR file to the compiler plugin classpath and specify annotations or presets:

```
-Xplugin=$KOTLIN_HOME/lib/noarg-compiler-plugin.jar
-P plugin:org.jetbrains.kotlin.noarg:annotation=com.my.Annotation
-P plugin:org.jetbrains.kotlin.noarg:preset=jpa
```

Experimental

Power-assert compiler plugin

The Kotlin Power-assert compiler plugin improves the debugging experience by providing detailed failure messages with contextual information. It simplifies the process of writing tests by automatically generating intermediate values in failure messages. It helps you understand why a test failed without needing complex assertion libraries.

This is an example message provided by the plugin:

```
Incorrect length
assert(hello.length == world.substring(1, 4).length) { "Incorrect length" }
       |     |      |  |     |               |
       |     5      |  |     "orl"           3
       "Hello"      |  "world!"
                    false
```

The Power-assert plugin key features:

- **Enhanced error messages**: The plugin captures and displays the values of variables and sub-expressions within the assertion to clearly identify the cause of failure.
- **Runtime library**: The library provides the `@PowerAssert` annotation and the `CallExplanation` class. They make Power-assert capable functions more discoverable and easier to configure by integrating them directly with the compiler plugin transformations.
- **Simplified testing**: Automatically generates informative failure messages, reducing the need for complex assertion libraries.
- **Support for multiple functions**: By default, it transforms `assert()` function calls but can also transform other functions, such as `require()`, `check()`, and `assertTrue()`.

Apply the plugin

Gradle

To enable the Power-assert plugin, configure your `build.gradle(.kts)` file as follows:

Kotlin

```kotlin
// build.gradle.kts
plugins {
    kotlin("multiplatform") version "2.4.20"
    kotlin("plugin.power-assert") version "2.4.20"
}
```

Groovy

```groovy
// build.gradle
plugins {
    id 'org.jetbrains.kotlin.multiplatform' version '2.4.20'
    id 'org.jetbrains.kotlin.plugin.power-assert' version '2.4.20'
}
```

The Power-assert plugin provides several options to customize its behavior:

- **`functions`** lists the fully qualified paths to functions that the Power-assert plugin transforms when they're called. If not specified, the plugin transforms only `kotlin.assert()` calls.
- **`compilationFilter`** controls which Kotlin compilations the Power-assert plugin is applied to. You can create your own custom filter or use the predefined options:
  - `PowerAssertCompilationFilter.TESTS` applies to all test source sets (default).
  - `PowerAssertCompilationFilter.ALL` applies to all source sets.

> The `compilationFilter` option has replaced the deprecated `includedSourceSets`, which listed Gradle source sets that the Power-assert plugin transforms. These two options are mutually exclusive: if `includedSourceSets` is specified, `compilationFilter` is ignored.

To customize the behavior, add the `powerAssert {}` block to your build script file:

Kotlin

```kotlin
// build.gradle.kts
powerAssert {
    functions = listOf("kotlin.assert", "kotlin.test.assertTrue", "kotlin.test.assertEquals",
"kotlin.test.assertNull")
    compilationFilter = PowerAssertCompilationFilter {
        it.name in setOf("commonMain", "jvmMain", "jsMain", "nativeMain")
    }
}
```

Groovy

```
// build.gradle
powerAssert {
    functions = ["kotlin.assert", "kotlin.test.assertTrue", "kotlin.test.assertEquals",
"kotlin.test.assertNull"]
    compilationFilter = PowerAssertCompilationFilter {
        it.name in ["commonMain", "jvmMain", "jsMain", "nativeMain"]
    }
}
```

Since the plugin is Experimental, you will see warnings every time you build your app. To exclude these warnings, add this `@OptIn` annotation before declaring the `powerAssert {}` block:

```
import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

@OptIn(ExperimentalKotlinGradlePluginApi::class)
powerAssert {
    ...
}
```

Maven

To enable the Power-assert compiler plugin in a Maven project, update the `<plugin>` section of `kotlin-maven-plugin` in the `pom.xml` file:

```
<build>
    <plugins>
        <plugin>
            <artifactId>kotlin-maven-plugin</artifactId>
            <groupId>org.jetbrains.kotlin</groupId>
            <version>2.4.20</version>
            <executions>
                <execution>
                    <id>compile</id>
                    <phase>process-sources</phase>
                    <goals>
                        <goal>compile</goal>
                    </goals>
                </execution>
                <execution>
                    <id>test-compile</id>
                    <phase>process-test-sources</phase>
                    <goals>
                        <goal>test-compile</goal>
                    </goals>
                </execution>
            </executions>

            <configuration>
                <!-- Specify the Power-assert plugin -->
                <compilerPlugins>
                    <plugin>power-assert</plugin>
                </compilerPlugins>
            </configuration>

            <!-- Add the Power-assert plugin dependency -->
            <dependencies>
                <dependency>
                    <groupId>org.jetbrains.kotlin</groupId>
                    <artifactId>kotlin-maven-power-assert</artifactId>
                    <version>2.4.20</version>
                </dependency>
            </dependencies>
        </plugin>
    </plugins>
</build>
```

You can customize which functions the Power-assert plugin transforms by using the `function` option. For example, you can include `kotlin.test.assertTrue()`, `kotlin.test.assertEquals()`, and others. If not specified, only `kotlin.assert()` calls are transformed by default.

Specify this option in the `<configuration>` section of `kotlin-maven-plugin`:

```
<configuration>
    <!-- Specify the functions to transform -->
    <pluginOptions>
        <option>power-assert:function=kotlin.assert</option>
        <option>power-assert:function=kotlin.test.assertTrue</option>
        <option>power-assert:function=kotlin.test.AssertEquals</option>
    </pluginOptions>
</configuration>
```

Use the Power-assert plugin

This section provides examples of using the Power-assert compiler plugin.

See the complete code of the build script file `build.gradle.kts` or `pom.xml` for all these examples:

Gradle (Kotlin)

```
// build.gradle.kts

import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

plugins {
    kotlin("multiplatform") version "2.4.20"
    kotlin("plugin.power-assert") version "2.4.20"
}

group = "com.example"
version = "1.0-SNAPSHOT"

repositories {
    mavenCentral()
}

dependencies {
    testImplementation(kotlin("test"))
}

tasks.test {
    useJUnitPlatform()
}

@OptIn(ExperimentalKotlinGradlePluginApi::class)
powerAssert {
    functions = listOf("kotlin.assert", "kotlin.test.assertEquals", "kotlin.test.assertTrue",
"kotlin.test.assertNull", "kotlin.require", "com.example.AssertScope.assert")
}
```

Gradle (Groovy)

```
// build.gradle
plugins {
    id 'org.jetbrains.kotlin.multiplatform' version '2.4.20'
    id 'org.jetbrains.kotlin.plugin.power-assert' version '2.4.20'
}

group = 'com.example'
version = '1.0-SNAPSHOT'

repositories {
    mavenCentral()
}

dependencies {
    testImplementation 'org.jetbrains.kotlin:kotlin-test'
}

test {
    useJUnitPlatform()
}

powerAssert {
    functions = [
            'kotlin.assert',
            'kotlin.test.assertEquals',
            'kotlin.test.assertTrue',
            'kotlin.test.assertNull',
            'kotlin.require',
            'com.example.AssertScope.assert'
    ]
}
```

Maven

```
<!-- pom.xml -->

                <executions>
                    <execution>
                        <id>compile</id>
                        <phase>compile</phase>
                        <goals>
                            <goal>compile</goal>
                        </goals>
                    </execution>
                    <execution>
                        <id>test-compile</id>
                        <phase>test-compile</phase>
                        <goals>
                            <goal>test-compile</goal>
                        </goals>
                    </execution>
                </executions>

                <configuration>
                    <compilerPlugins>
                        <plugin>power-assert</plugin>
                    </compilerPlugins>

                    <pluginOptions>
                        <option>power-assert:function=kotlin.assert</option>
                        <option>power-assert:function=kotlin.require</option>
                        <option>power-assert:function=kotlin.test.assertTrue</option>
                        <option>power-assert:function=kotlin.test.assertEquals</option>
```

```
                        <option>power-assert:function=kotlin.test.assertNull</option>
                        <option>power-assert:function=com.example.AssertScope.assert</option>
                    </pluginOptions>
                </configuration>

                <dependencies>
                    <dependency>
                        <groupId>org.jetbrains.kotlin</groupId>
                        <artifactId>kotlin-maven-power-assert</artifactId>
                        <version>2.4.20</version>
                    </dependency>
                </dependencies>

            </plugin>
            <plugin>
                <artifactId>maven-surefire-plugin</artifactId>
                <version>2.22.2</version>
            </plugin>
            <plugin>
                <artifactId>maven-failsafe-plugin</artifactId>
                <version>2.22.2</version>
            </plugin>
            <plugin>
                <groupId>org.codehaus.mojo</groupId>
                <artifactId>exec-maven-plugin</artifactId>
                <version>1.6.0</version>
                <configuration>
                    <mainClass>MainKt</mainClass>
                </configuration>
            </plugin>
        </plugins>
    </build>

    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-test-junit5</artifactId>
            <version>2.4.20</version>
            <scope>test</scope>
        </dependency>
        <dependency>
            <groupId>org.junit.jupiter</groupId>
            <artifactId>junit-jupiter</artifactId>
            <version>5.10.0</version>
            <scope>test</scope>
        </dependency>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-stdlib</artifactId>
            <version>2.4.20</version>
        </dependency>
    </dependencies>
</project>
```

`@PowerAssert`-annotated functions

If a function is annotated with `@PowerAssert`, the Power-assert plugin transforms calls to it automatically. You don't need to register the function in your build configuration.

You can add `@PowerAssert` annotations when declaring assertion functions yourself, or use libraries that support Power-assert and provide annotated functions.

To get detailed failure messages, call the function with the Power-assert plugin enabled in your project:

```
import kotlin.test.Test

data class Mascot(val name: String)

class SampleTest {

    @Test
    fun testAnnotatedFunction() {
        val subject: Any? = Mascot(name = "Unknown")
        // If assertThat() is annotated with @PowerAssert in the library,
        // the plugin transforms this call automatically
        assertThat(subject) {
            require(subject is Mascot)
            check(subject.name == "Kodee")
        }
    }
}
```

The plugin provides detailed failure messages with intermediate expression values:

```
check(subject.name == "Kodee")
      |       |    |
      |       |    false
      |       "Unknown"
      Mascot(name=Unknown)
```

Assert function

Consider the following test with the `assert()` function:

```
import kotlin.test.Test

class SampleTest {

    @Test
    fun testFunction() {
        val hello = "Hello"
        val world = "world!"
        assert(hello.length == world.substring(1, 4).length) { "Incorrect length" }
    }
}
```

If you run the `testFunction()` test with the Power-assert plugin enabled, you get the explicit failure message:

```
Incorrect length
assert(hello.length == world.substring(1, 4).length) { "Incorrect length" }
       |     |      |  |     |               |
       |     5      |  |     "orl"           3
       "Hello"      |  "world!"
                    false
```

To get a more complete error message, always inline the variable into the test function parameters. Consider the following test function:

```
class ComplexExampleTest {

    data class Person(val name: String, val age: Int)

    @Test
    fun testComplexAssertion() {
        val person = Person("Alice", 10)
        val isValidName = person.name.startsWith("A") && person.name.length > 3
        val isValidAge = person.age in 21..28
        assert(isValidName && isValidAge)
    }
}
```

The output of the executed code doesn't provide enough information to find the cause of the problem:

```
assert(isValidName && isValidAge)
       |              |
       true           false
```

Inline the variable into the `assert()` function:

```
class ComplexExampleTest {

    data class Person(val name: String, val age: Int)

    @Test
    fun testComplexAssertion() {
        val person = Person("Alice", 10)
        assert(person.name.startsWith("A") && person.name.length > 3 && person.age > 20 && person.age
< 29)
    }
}
```

After execution, you get more explicit information about what went wrong:

```
assert(person.name.startsWith("A") && person.name.length > 3 && person.age > 20 && person.age < 29)
       |      |    |                 |      |    |      |      |      |   |
       |      |    true              |      |    5      true   |      10  false
       |      "Alice"                |      "Alice"            Person(name=Alice, age=10)
       Person(name=Alice, age=10)    Person(name=Alice, age=10)
```

Beyond assert function

The Power-assert plugin can transform various functions beyond `assert` which is transformed by default. Functions like `require()`, `check()`, `assertTrue()`, `assertEqual()` and others can also be transformed, if they have a form that allows taking a `String` or `() -> String` value as the last parameter.

Before using a new function in a test, add the function to your build file. For example, the `require()` function:

Gradle (Kotlin)

```kotlin
// build.gradle.kts
import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

@OptIn(ExperimentalKotlinGradlePluginApi::class)
powerAssert {
    functions = listOf("kotlin.assert", "kotlin.require")
}
```

Gradle (Groovy)

```groovy
powerAssert {
    functions = [
            'kotlin.assert',
            'kotlin.require'
    ]
}
```

Maven

```xml
<!-- pom.xml -->
<configuration>
    <pluginOptions>
        <option>power-assert:function=kotlin.assert</option>
        <option>power-assert:function=kotlin.require</option>
    </pluginOptions>
</configuration>
```

After adding the function, you can use it in your tests:

```kotlin
class RequireExampleTest {

    @Test
    fun testRequireFunction() {
        val value = ""
        require(value.isNotEmpty()) { "Value should not be empty" }
    }
}
```

The output for this example uses the Power-assert plugin to provide detailed information about the failed test:

```
Value should not be empty
require(value.isNotEmpty()) { "Value should not be empty" }
        |     |
        ""    false
```

The message shows the intermediate values that lead to the failure, making it easier to debug.

Soft assertions

The Power-assert plugin supports soft assertions, which do not immediately fail the test but instead collect assertion failures and report them at the end of the test run. This can be useful when you want to see all assertion failures in a single run without stopping at the first failure.

To enable soft assertions, implement the way you will collect error messages:

```
fun <R> assertSoftly(block: AssertScope.() -> R): R {
    val scope = AssertScopeImpl()
    val result = scope.block()
    if (scope.errors.isNotEmpty()) {
        throw AssertionError(scope.errors.joinToString("\n"))
    }
    return result
}

interface AssertScope {
    fun assert(assertion: Boolean, message: (() -> String)? = null)
}

class AssertScopeImpl : AssertScope {
    val errors = mutableListOf<String>()
    override fun assert(assertion: Boolean, message: (() -> String)?) {
        if (!assertion) {
            errors.add(message?.invoke() ?: "Assertion failed")
        }
    }
}
```

Add these functions to your build file to make them available for the Power-assert plugin:

Gradle (Kotlin)

```
// build.gradle.kts
import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

@OptIn(ExperimentalKotlinGradlePluginApi::class)
powerAssert {
    functions = listOf("kotlin.assert", "kotlin.test.assert", "com.example.AssertScope.assert")
}
```

Gradle (Groovy)

```
powerAssert {
    functions = [
            'kotlin.assert',
            'kotlin.test.assert',
            'com.example.AssertScope.assert'
    ]
}
```

Maven

```
<!-- pom.xml -->
<configuration>
    <pluginOptions>
        <option>power-assert:function=kotlin.assert</option>
        <option>power-assert:function=kotlin.require</option>
        <option>power-assert:function=com.example.AssertScope.assert</option>
    </pluginOptions>
</configuration>
```

You should specify the full name of the package where you declare the `AssertScope.assert()` function.

After that, you could use it in your test code:

```
// Import the assertSoftly() function
import com.example.assertSoftly

class SoftAssertExampleTest1 {

    data class Employee(val name: String, val age: Int, val salary: Int)

    @Test
    fun `test employees data`() {
        val employees = listOf(
            Employee("Alice", 30, 60000),
            Employee("Bob", 45, 80000),
            Employee("Charlie", 55, 40000),
            Employee("Dave", 150, 70000)
        )

        assertSoftly {
            for (employee in employees) {
                assert(employee.age < 100) { "${employee.name} has an invalid age: ${employee.age}" }
                assert(employee.salary > 50000) { "${employee.name} has an invalid salary:
${employee.salary}" }
            }
        }
    }
}
```

In the output, all the `assert()` function error messages will be printed one after another:

```
Charlie has an invalid salary: 40000
assert(employee.salary > 50000) { "${employee.name} has an invalid salary: ${employee.salary}" }
       |        |      |
       |        40000  false
       Employee(name=Charlie, age=55, salary=40000)

Dave has an invalid age: 150
assert(employee.age < 100) { "${employee.name} has an invalid age: ${employee.age}" }
       |        |   |
       |        150 false
       Employee(name=Dave, age=150, salary=70000)
```

Add support for Power-assert to your library

If you are a library author, you can add out-of-the-box Power-assert support to your library using the `@PowerAssert` annotation and the `CallExplanation` class from the Power-assert runtime library.

The `@PowerAssert` annotation

The `@PowerAssert` annotation marks a function as Power-assert capable. If users of your library have the Power-assert compiler plugin in their projects and make calls to your annotated functions, the calls are automatically transformed without additional build configuration.

To add support for Power-assert to your library:

1. In your build file, apply the Power-assert plugin.
2. For Maven, add the Power-assert runtime library as a dependency:

```
<!-- pom.xml -->
<dependencies>
    <dependency>
        <groupId>org.jetbrains.kotlin</groupId>
        <artifactId>kotlin-power-assert-runtime</artifactId>
        <version>2.4.20</version>
    </dependency>
</dependencies>
```

   For Gradle, this dependency is automatically added with the Power-assert compiler plugin.

3. Annotate your assertion functions with `@PowerAssert`:

```
import kotlin.powerassert.PowerAssert
import kotlin.powerassert.toDefaultMessage
import kotlin.contracts.ExperimentalContracts
import kotlin.contracts.contract

@OptIn(ExperimentalContracts::class)
@PowerAssert
fun powerAssert(condition: Boolean, @PowerAssert.Ignore message: String? = null) {
    contract { returns() implies condition }
    if (!condition) {
        val explanation = PowerAssert.explanation
            ?: fail(message)

        val equalityErrors = buildList {
            for (expression in explanation.expressions) {
                if (expression is EqualityExpression && expression.value == false) {
                    add(expression)
                }
            }
        }

        val failureMessage = buildString {
            if (message?.isNotBlank() == true) appendLine(message)
            append(explanation.toDefaultMessage())
        }

        fail(failureMessage, equalityErrors)
    }
}
```

- The `PowerAssert.explanation` property provides access to the `CallExplanation` object containing the call site information.
- The `toDefaultMessage()` function renders the standard Power-assert failure message.
- The `@PowerAssert.Ignore` annotation on the `message` parameter excludes it from the failure message.

The compiler plugin detects the `@PowerAssert` annotation and transforms calls to the function at compile time.

For a complete example, see the `kotlin-test-power-assert` project.

The `CallExplanation` class

The `CallExplanation` class provides detailed information about the call site, including intermediate expression values. This enables dynamic message rendering for assertion failures and better integration with external tools.

When a function in your library is annotated with `@PowerAssert` and the compiler plugin is applied, the transformation is performed automatically at each call site. The `PowerAssert.explanation` property provides access to the `CallExplanation` object inside the function body.

The `PowerAssert.explanation` property can return `null` if the annotated function is called from Java, from a project where the Power-assert plugin is not applied, or via reflection.

Here is an example of how to use `CallExplanation` inside `@PowerAssert`-annotated functions to extract source code information and build custom failure messages:

```
package kotlinx.test.fluent

import kotlin.powerassert.PowerAssert
import kotlin.contracts.ExperimentalContracts
import kotlin.contracts.contract

@PowerAssert
fun AssertScope<*>.check(condition: Boolean) {
    if (!condition) {
        val explanation = PowerAssert.explanation
        val message = if (explanation == null) null else {
            val conditionArg = explanation.arguments.last()!!
            val source = explanation.source.substring(conditionArg.startOffset,
conditionArg.endOffset)
            "Condition failed: $source"
        }
        collect(message, explanation)
    }
}

@OptIn(ExperimentalContracts::class)
@PowerAssert
fun AssertScope<*>.require(condition: Boolean) {
    contract { returns() implies condition }
    if (!condition) {
        val explanation = PowerAssert.explanation
        val message = if (explanation == null) null else {
            val conditionArg = explanation.arguments.last()!!
            val source = explanation.source.substring(conditionArg.startOffset,
conditionArg.endOffset)
            "Condition failed: $source"
        }
        fail(message, explanation)
    }
}
```

In this example, the `check()` function collects failures for later reporting, while the `require()` function fails immediately. Both functions use `CallExplanation` to extract the source code of the failed condition and include it in the failure message.

For a complete example, see the `fluent-assert` project.

What's next

Look through our sample projects:

- A simple project with the plugin enabled
- A more complex project with multiple source sets
- Example collection for experimenting with runtime library features

SAM-with-receiver compiler plugin

The *sam-with-receiver* compiler plugin makes the first parameter of the annotated Java "single abstract method" (SAM) interface method a receiver in Kotlin. This conversion only works when the SAM interface is passed as a

Kotlin lambda, both for SAM adapters and SAM constructors (see the SAM conversions documentation for more details).

Here is an example:

```
public @interface SamWithReceiver {}

@SamWithReceiver
public interface TaskRunner {
    void run(Task task);
}
```

```
fun test(context: TaskContext) {
    val runner = TaskRunner {
        // Here 'this' is an instance of 'Task'

        println("$name is started")
        context.executeTask(this)
        println("$name is finished")
    }
}
```

Gradle

The usage is the same to all-open and no-arg, except the fact that sam-with-receiver does not have any built-in presets, and you need to specify your own list of special-treated annotations.

Kotlin

```
plugins {
    kotlin("plugin.sam.with.receiver") version "2.4.20"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.plugin.sam.with.receiver" version "2.4.20"
}
```

Then specify the list of SAM-with-receiver annotations:

```
samWithReceiver {
    annotation("com.my.SamWithReceiver")
}
```

Maven

```
<plugin>
    <artifactId>kotlin-maven-plugin</artifactId>
    <groupId>org.jetbrains.kotlin</groupId>
    <version>${kotlin.version}</version>

    <configuration>
        <compilerPlugins>
            <plugin>sam-with-receiver</plugin>
        </compilerPlugins>

        <pluginOptions>
            <option>
                sam-with-receiver:annotation=com.my.SamWithReceiver
            </option>
        </pluginOptions>
    </configuration>

    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-sam-with-receiver</artifactId>
            <version>${kotlin.version}</version>
        </dependency>
    </dependencies>
</plugin>
```

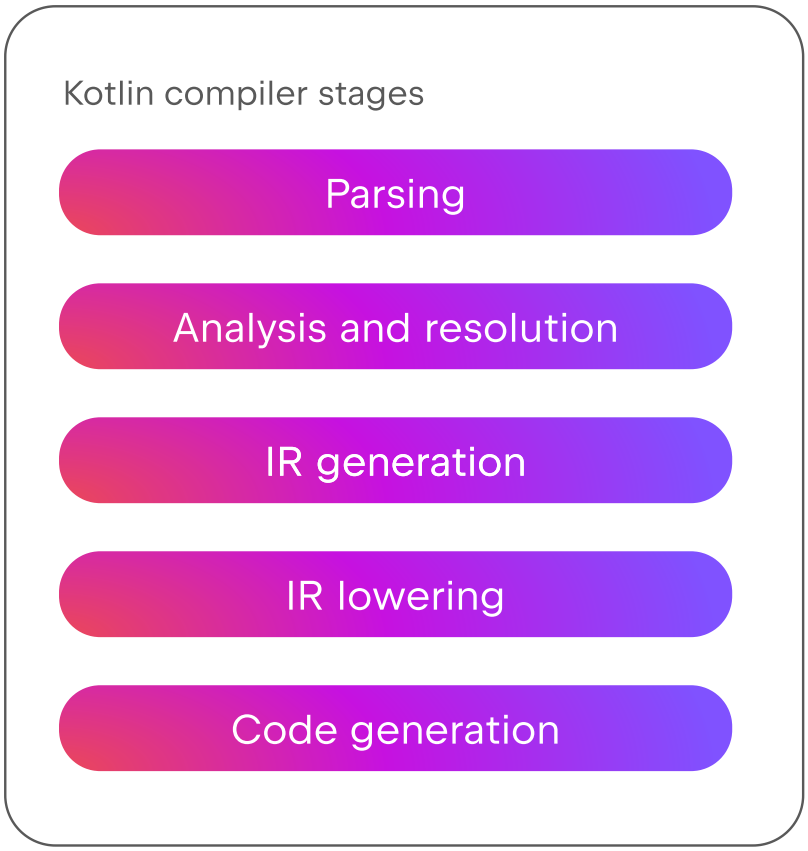
Command-line compiler

Add the plugin JAR file to the compiler plugin classpath and specify the list of sam-with-receiver annotations:

```
-Xplugin=$KOTLIN_HOME/lib/sam-with-receiver-compiler-plugin.jar
-P plugin:org.jetbrains.kotlin.samWithReceiver:annotation=com.my.SamWithReceiver
```

Custom compiler plugins

The Kotlin compiler plugin API is unstable and introduces breaking changes in every release.



Compiler plugins hook into the compilation process to analyze or change code while it's being compiled, without modifying the compiler itself. For example, they can annotate code or generate new code to make it compatible with other frameworks or APIs.

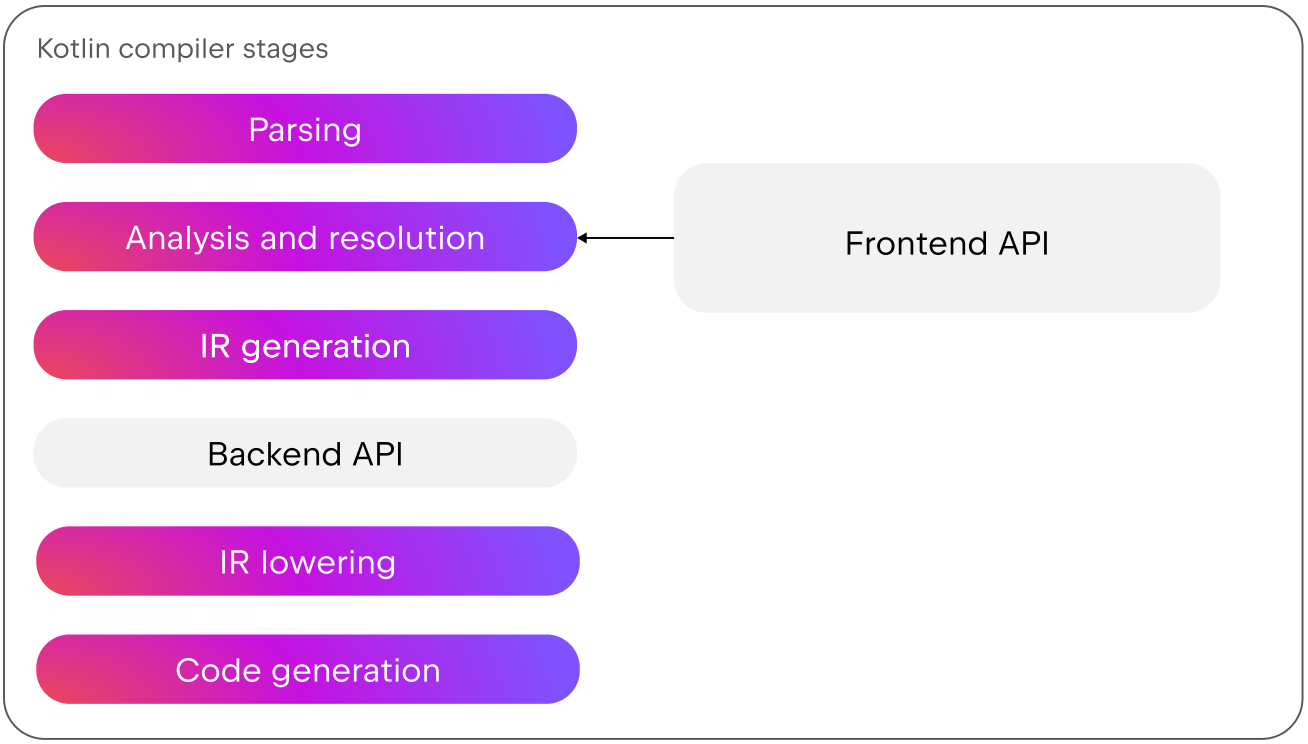
Before you create your own custom compiler plugin, check the list of available compiler plugins to see if one is already available that suits your use case.

You can also check whether you can use the Kotlin Symbol Processing (KSP) API or an external linter such as Android lint to achieve your goals.

If you *still* can't find what you need, you can create a custom compiler plugin. Be aware that the Kotlin compiler plugin API is **unstable**. You need to invest significant ongoing effort to maintain it, since each new compiler release introduces breaking changes.

The Kotlin compiler and compiler plugins

Kotlin compiler stages



The Kotlin compiler:

1. Parses the source code and turns it into a structured syntax tree.
2. Analyzes and resolves the code by determining what it means, resolving names, checking types, and enforcing visibility rules.
3. Generates an Intermediate Representation (IR), a data structure that acts as a bridge between source code and machine code.
4. Progressively lowers the IR into simpler forms.
5. Translates the lowered IR into target-specific output, such as JVM bytecode, JavaScript, or native machine code.

Plugins can affect the initial compiler stages through the frontend API, changing how the compiler resolves code. For example, a plugin can add annotations or introduce new methods without bodies, or change visibility modifiers. These changes are visible in the IDE.

Plugins can also affect the later stages through the backend API, modifying the behavior of declarations. These changes appear in the binaries produced after compilation completes.

In practice, compiler plugins affect the stages from analysis and resolution through code generation, covering both frontend and backend. For example, the frontend part generates declarations, and the backend part adds bodies for those declarations.

Kotlin compiler stages with plugins

The Kotlin serialization plugin is a good example. The plugin's frontend part adds a companion object and a serializer function, as well as checks to prevent name conflicts. The backend part implements the desired serialization behavior through `KSerializer` objects.

Kotlin compiler plugin template

To start writing a custom compiler plugin, you can use the Kotlin compiler plugin template. You then register extension points from the frontend and backend plugin APIs.

Currently, you can develop custom compiler plugins only with Gradle.

Frontend plugin API

The frontend plugin API, also known as frontend intermediate representation (FIR), has the following specialized extension points to customize resolution:

Extension name	Description
`FirAdditionalCheckersExtension`	Adds custom compiler checkers.
`FirDeclarationGenerationExtension`	Generates new declarations.
`FirExtensionSessionComponent`	Registers custom components in the `FirSession` to be used by other parts of the plugin.

Extension name	Description
`FirFunctionTypeKindExtension`	Defines new families of functional types.
`FirMetadataSerializerPlugin`	Reads and writes information to declaration metadata.
`FirStatusTransformerExtension`	Modifies declaration status attributes such as visibility or modality.
`FirSupertypeGenerationExtension`	Adds new supertypes to an existing class.
`FirTypeAttributeExtension`	Adds special attributes to certain types based on their type annotations.

IDE integration

Resolution changes affect IDE behavior such as code highlighting and suggestions, so it's important that your plugin is compatible with the IDE. Each version of IntelliJ IDEA and Android Studio includes a development version of the Kotlin compiler. This version is specific to the IDE and is not binary compatible with the released Kotlin compiler. As a result, when you update your IDE, you also need to update your compiler plugin to keep it working. For this reason, community plugins aren't loaded by default.

To ensure that your custom compiler plugin works with different IDE versions, test it against each IDE version and fix any issues you find.

Supporting multiple IDE versions could become easier if a devkit for Kotlin compiler plugins were available. If you're interested in this feature, share your feedback in our issue tracker.

Backend plugin API

> Backend plugin development is difficult to do correctly without degrading IDE or debugger performance, so be careful and conservative with your changes.

The backend plugin API, also known as IR, has a single extension point: `IrGenerationExtension`. Use this extension point and override the `generate()` function to add bodies to declarations already generated by the frontend or change existing declaration bodies.

Changes made through this extension point are **not checked** by the compiler. You must ensure that your changes don't break the compiler's expectations at this stage. For example, you might accidentally introduce an invalid type, an incorrect function reference, or a reference outside the correct scope.

Explore backend plugin code

You can explore the Kotlin serialization plugin code to see what backend plugin compiler code looks like in practice. For example, `SerializableCompanionIrGenerator.kt` fills in missing bodies for key serializer members. One example is the `generateChildSerializersGetter()` function, which collects a list of `KSerializer` expressions and returns them in an array.

Check your backend plugin code for problems

You can check for problems in your backend plugin code in three ways:

1. **Verify the IR**

   Build the IR tree and enable the `Xverify-ir` compiler option. This option has a performance impact on compilation speed, so use it only during testing.

2. **Dump and compare IR output**

   Create a dump file after the IR lowering compilation stage with the `-Xphases-to-dump-before=ExternalPackageParentPatcherLowering` compiler option. For the JVM backend, configure the dump directory with the `-Xdump-directory=<your-file-directory>` compiler option. Write the expected code manually, generate another dump file, and compare the two to see if there are differences.

3. **Debug the compiler code**

   In the `convertToIr.kt` file, add breakpoints in the `convertToIrAndActualize()` function and run the compiler in debug mode to get more detailed information during compilation.

Test your plugin

Once you implement your plugin, test it thoroughly. The Kotlin compiler plugin template is already set up to use the Kotlin compiler test framework. You can add tests in the following directories:

- `compiler-plugin/testData`
- `compiler-plugin/testData/box` for code generation tests
- `compiler-plugin/testData/diagnostics` for diagnostic tests

When a test runs, the framework:

1. Parses the test source file. For example, `anotherBoxTest.kt`
2. Builds the FIR and IR for each file.
3. Writes these as textual dump files. For example, `anotherBoxTest.fir.txt` and `anotherBoxTest.fir.ir.txt` .
4. Compares these files with previously created files, if they exist.

You can use these files to check if any changes in the generated diff weren't intended. If there are no problems, the new dump files become your latest *golden* files: an approved and trusted source that you can compare future changes against.

Get help

If you run into issues developing a custom compiler plugin, reach out in Kotlin Slack in the #compiler channel. We can't promise a solution but we will try to help if we can.

Compose compiler migration guide

The Compose compiler is supplemented by a Gradle plugin, which simplifies setup and offers easier access to compiler options. When applied with the Android Gradle plugin (AGP), this Compose compiler plugin will override the coordinates of the Compose compiler supplied automatically by AGP.

The Compose compiler has been merged into the Kotlin repository since Kotlin 2.0.0. This helps smooth the migration of your projects to Kotlin 2.0.0 and later, as the Compose compiler ships simultaneously with Kotlin and will always be compatible with Kotlin of the same version.

To use the new Compose compiler plugin in your project, apply it for each module that uses Compose. Read on for details on how to migrate a Jetpack Compose project. For a Compose Multiplatform project, refer to the multiplatform migration guide.

Migrating a Jetpack Compose project

When migrating to Kotlin 2.0.0 or newer from 1.9, you should adjust your project configuration depending on the way you deal with the Compose compiler. We recommend using the Kotlin Gradle plugin and the Compose compiler Gradle plugin to automate configuration management.

Managing the Compose compiler with Gradle plugins

For Android modules:

1. Add the Compose compiler Gradle plugin to the Gradle version catalog:

```
[versions]
# ...
kotlin = "2.4.20"

[plugins]
# ...
org-jetbrains-kotlin-android = { id = "org.jetbrains.kotlin.android", version.ref = "kotlin" }
compose-compiler = { id = "org.jetbrains.kotlin.plugin.compose", version.ref = "kotlin" }
```

> If you're using AGP 9.0.0 or later, you no longer need the `org-jetbrains-kotlin-android` plugin because the AGP has built-in Kotlin support.

2. Add the Gradle plugin to the root `build.gradle.kts` file:

```
plugins {
    // ...
    alias(libs.plugins.compose.compiler) apply false
}
```

3. Apply the plugin to every module that uses Jetpack Compose:

```
plugins {
    // ...
    alias(libs.plugins.compose.compiler)
}
```

4. If you are using compiler options for the Jetpack Compose compiler, set them in the `composeCompiler {}` block. See the list of compiler options for reference.

5. If you reference Compose compiler artifacts directly, you can remove these references and let the Gradle plugins take care of things.

Using Compose compiler without Gradle plugins

If you are not using Gradle plugins to manage the Compose compiler, update any direct references to old Maven artifacts in your project:

- Change `androidx.compose.compiler:compiler` to `org.jetbrains.kotlin:kotlin-compose-compiler-plugin-embeddable`
- Change `androidx.compose.compiler:compiler-hosted` to `org.jetbrains.kotlin:kotlin-compose-compiler-plugin`

What's next

- See Google's announcement about the Compose compiler moving to the Kotlin repository.
- If you are using Jetpack Compose to build an Android app, check out our guide on how to make it multiplatform.

Compose compiler options DSL

The Compose compiler Gradle plugin offers a DSL for various compiler options. You can use it to configure the compiler in the `composeCompiler {}` block of the `build.gradle.kts` file for the module you're applying the plugin to.

There are two kinds of options you can specify:

- General compiler settings, which can be disabled or enabled as needed in any given project.
- Feature flags that enable or disable new and experimental features, which should eventually become part of the baseline.

You can find the list of available general settings and the list of supported feature flags in the Compose compiler Gradle plugin API reference.

Here's an example configuration:

```
composeCompiler {
    includeSourceInformation = true

    featureFlags = setOf(
        ComposeFeatureFlag.StrongSkipping.disabled(),
        ComposeFeatureFlag.OptimizeNonSkippingGroups
    )
}
```

The Gradle plugin provides defaults for several Compose compiler options that were only specified manually before Kotlin 2.0. If you have any of them set up with `freeCompilerArgs`, for example, Gradle reports a duplicate options error.

Purpose and use of feature flags

Feature flags are organized into a separate set of options to minimize changes to top-level properties as new flags are continuously rolled out and deprecated.

To enable a feature flag that is disabled by default, specify it in the set, for example:

```
featureFlags = setOf(ComposeFeatureFlag.OptimizeNonSkippingGroups)
```

To disable a feature flag that is enabled by default, call the `disabled()` function on it, for example:

```
featureFlags = setOf(ComposeFeatureFlag.StrongSkipping.disabled())
```

If you are configuring the Compose compiler directly, use the following syntax to pass feature flags to it:

```
-P plugin:androidx.compose.compiler.plugins.kotlin:featureFlag=<flag name>
```

See the list of supported feature flags in the Compose compiler Gradle plugin API reference.

Kotlin Symbol Processing API

Kotlin Symbol Processing (KSP) is a source code generation framework for Kotlin. With the KSP API, you can create processors that generate code based on annotations in your source code.

KSP aims to simplify the creation of lightweight compiler plugins. Its well-defined API hides compiler changes, so you don't need to spend much effort maintaining your processors. However, this approach comes with trade-offs. For example, KSP-based processors can't examine expressions or statements, and they can't modify the source code.

Typical use cases for KSP-based plugins include:

- Dependency injection (Dagger)
- Serialization (Moshi)
- Database management (Room)

To learn how to create your first KSP-based processor, see the KSP quickstart.

Overview

The KSP API processes Kotlin programs idiomatically. KSP understands Kotlin-specific features, such as extension functions, declaration-site variance, and local functions. It also models types explicitly and provides basic type checking, such as equivalence and assign-compatibility.

The API models Kotlin program structures at the symbol level according to Kotlin grammar. When KSP-based plugins process source programs, constructs like classes, class members, functions, and associated parameters are accessible for the processors, while things like `if` blocks and `for` loops are not.

Conceptually, KSP is similar to KType in Kotlin reflection. The API allows processors to navigate from class declarations to corresponding types with specific type arguments and vice versa. You can also substitute type arguments, specify variances, apply star projections, and mark nullabilities of types.

Another way to think of KSP is as a preprocessor framework of Kotlin programs. By considering KSP-based plugins as *symbol processors*, or simply *processors*, the data flow in a compilation can be described in the following steps:

1. Processors read and analyze source programs and resources.
2. Processors generate code or other forms of output.

3. The Kotlin compiler compiles the source programs together with the generated code.

Unlike a full-fledged compiler plugin, processors cannot modify the code. A compiler plugin that changes language semantics can sometimes be very confusing. KSP avoids that by treating the source programs as read-only.

You can also get an overview of KSP in this video:

Watch video online.

How KSP looks at source files

Most processors navigate through the various program structures of the input source code. Before diving into usage of the API, let's see at how a file might look from KSP's point of view:

```
KSFile
  packageName: KSName
  fileName: String
  annotations: List<KSAnnotation>  (File annotations)
  declarations: List<KSDeclaration>
    KSClassDeclaration // class, interface, object
      simpleName: KSName
      qualifiedName: KSName
      containingFile: String
      typeParameters: KSTypeParameter
      parentDeclaration: KSDeclaration
      classKind: ClassKind
      primaryConstructor: KSFunctionDeclaration
      superTypes: List<KSTypeReference>
      // contains inner classes, member functions, properties, etc.
      declarations: List<KSDeclaration>
    KSFunctionDeclaration // top level function
      simpleName: KSName
      qualifiedName: KSName
      containingFile: String
      typeParameters: KSTypeParameter
      parentDeclaration: KSDeclaration
      functionKind: FunctionKind
      extensionReceiver: KSTypeReference?
      returnType: KSTypeReference
      parameters: List<KSValueParameter>
      // contains local classes, local functions, local variables, etc.
      declarations: List<KSDeclaration>
    KSPropertyDeclaration // global variable
      simpleName: KSName
      qualifiedName: KSName
      containingFile: String
      typeParameters: KSTypeParameter
      parentDeclaration: KSDeclaration
      extensionReceiver: KSTypeReference?
      type: KSTypeReference
      getter: KSPropertyGetter
        returnType: KSTypeReference
      setter: KSPropertySetter
        parameter: KSValueParameter
```

This view lists common things that are declared in the file: classes, functions, properties, and so on.

SymbolProcessorProvider: the entry point

KSP expects an implementation of the `SymbolProcessorProvider` interface to instantiate `SymbolProcessor`:

```
interface SymbolProcessorProvider {
    fun create(environment: SymbolProcessorEnvironment): SymbolProcessor
}
```

While `SymbolProcessor` is defined as:

```
interface SymbolProcessor {
    fun process(resolver: Resolver): List<KSAnnotated> // Let's focus on this
    fun finish() {}
    fun onError() {}
}
```

A `Resolver` provides `SymbolProcessor` with access to compiler details such as symbols. A processor that finds all top-level functions and non-local functions in top-level classes might look something like the following:

```
class HelloFunctionFinderProcessor : SymbolProcessor() {
    // ...
    val functions = mutableListOf<KSFunctionDeclaration>()
    val visitor = FindFunctionsVisitor()

    override fun process(resolver: Resolver) {
        resolver.getAllFiles().forEach { it.accept(visitor, Unit) }
    }

    inner class FindFunctionsVisitor : KSVisitorVoid() {
        override fun visitClassDeclaration(classDeclaration: KSClassDeclaration, data: Unit) {
            classDeclaration.getDeclaredFunctions().forEach { it.accept(this, Unit) }
        }

        override fun visitFunctionDeclaration(function: KSFunctionDeclaration, data: Unit) {
            functions.add(function)
        }

        override fun visitFile(file: KSFile, data: Unit) {
            file.declarations.forEach { it.accept(this, Unit) }
        }
    }
    // ...

    class Provider : SymbolProcessorProvider {
        override fun create(environment: SymbolProcessorEnvironment): SymbolProcessor = TODO()
    }
}
```

Supported libraries

The table includes a list of popular libraries on Android and their various stages of support for KSP:

Library	Status
Room	Officially supported
Moshi	Officially supported
RxHttp	Officially supported
Kotshi	Officially supported
Lyricist	Officially supported
Lich SavedState	Officially supported
gRPC Dekorator	Officially supported
EasyAdapter	Officially supported
Koin Annotations	Officially supported
Glide	Officially supported
Micronaut	Officially supported
Epoxy	Officially supported
Paris	Officially supported
Auto Dagger	Officially supported
SealedX	Officially supported
Ktorfit	Officially supported

Library	Status
Mockative	Officially supported
Kotest	Officially supported
DeeplinkDispatch	Supported via airbnb/DeepLinkDispatch#323
Dagger	Alpha
Motif	Alpha
Hilt	In progress
Auto Factory	Not yet supported

Getting started with KSP

In this guide, you will learn:

- How to add KSP-based annotation processors to your project.
- How to create your own annotation processor with the KSP API.
- Where to find the code generated by the processor.

Add a KSP-based processor to your project

To use an external processor in your project, add KSP to the `plugins {}` block in your `build.gradle(.kts)` file. If the processor is only needed in a specific module, add it to that module's `build.gradle(.kts)` file instead:

Kotlin

```
// build.gradle.kts

plugins {
    kotlin("jvm") version "2.4.20"
    id("com.google.devtools.ksp") version "2.3.10"
}
```

Groovy

```
// build.gradle

plugins {
    id 'org.jetbrains.kotlin.jvm' version '2.4.20'
```

```
    id 'com.google.devtools.ksp' version '2.3.10'
}
```

To find the latest version of KSP, check the GitHub Releases.

In the top-level `dependencies {}` block, add the processor you want to use. This example uses Moshi, but the approach is the same for other processors:

Kotlin

```
// build.gradle.kts

dependencies {
    ksp("com.squareup.moshi:moshi-kotlin-codegen:1.15.2")
}
```

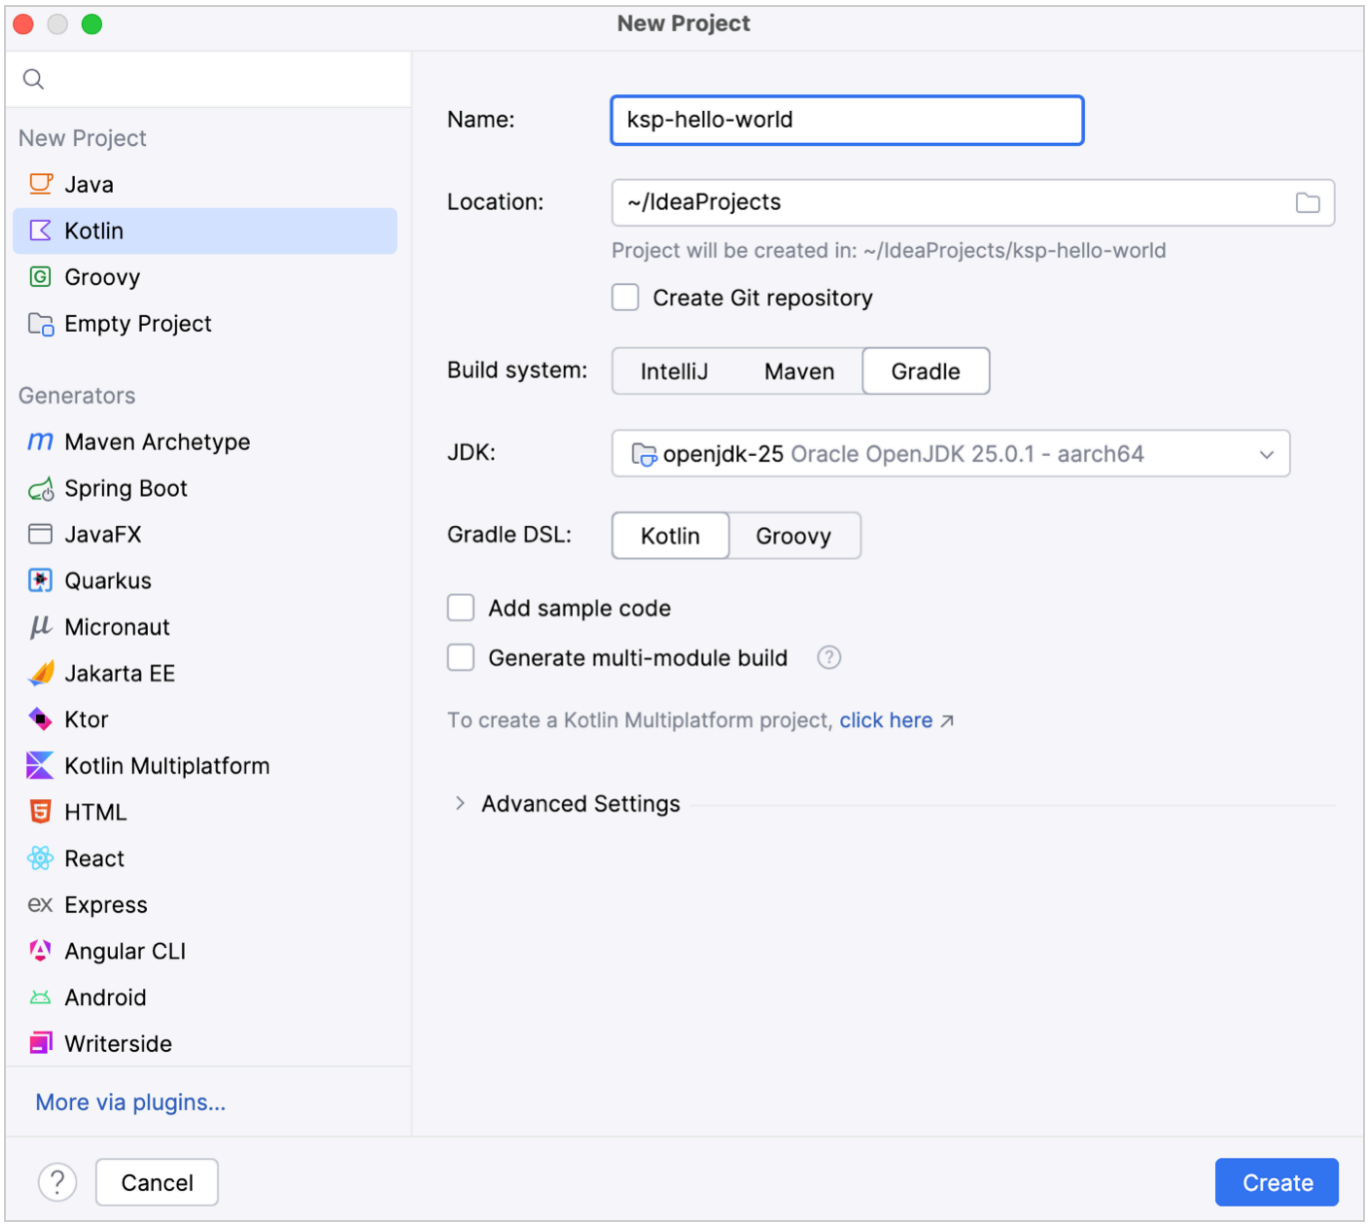
Groovy

```
// build.gradle

dependencies {
    ksp 'com.squareup.moshi:moshi-kotlin-codegen:1.15.2'
}
```

The `ksp(...)` configuration applies the processor only to application sources. To process test sources, add the processor with the `kspTest(...)` configuration.

The `ksp(...)` configuration is available only in single-platform projects. To learn how to configure processors for individual Kotlin Multiplatform targets and compilations, see KSP with Kotlin Multiplatform.



Create your own processor

By following these steps you will create a simple annotation processor that will generate a `helloWorld()` function. While not very useful in practice, it demonstrates the basics of creating your own processors and annotations.

Add KSP to the project

Create a new Kotlin project and add the KSP plugin:

1. In IntelliJ IDEA, select **File** | **New** | **Project**.
2. In the list on the left, choose **Kotlin**.
3. Choose **Gradle** as the build system and click **Create**.

Creating a new project

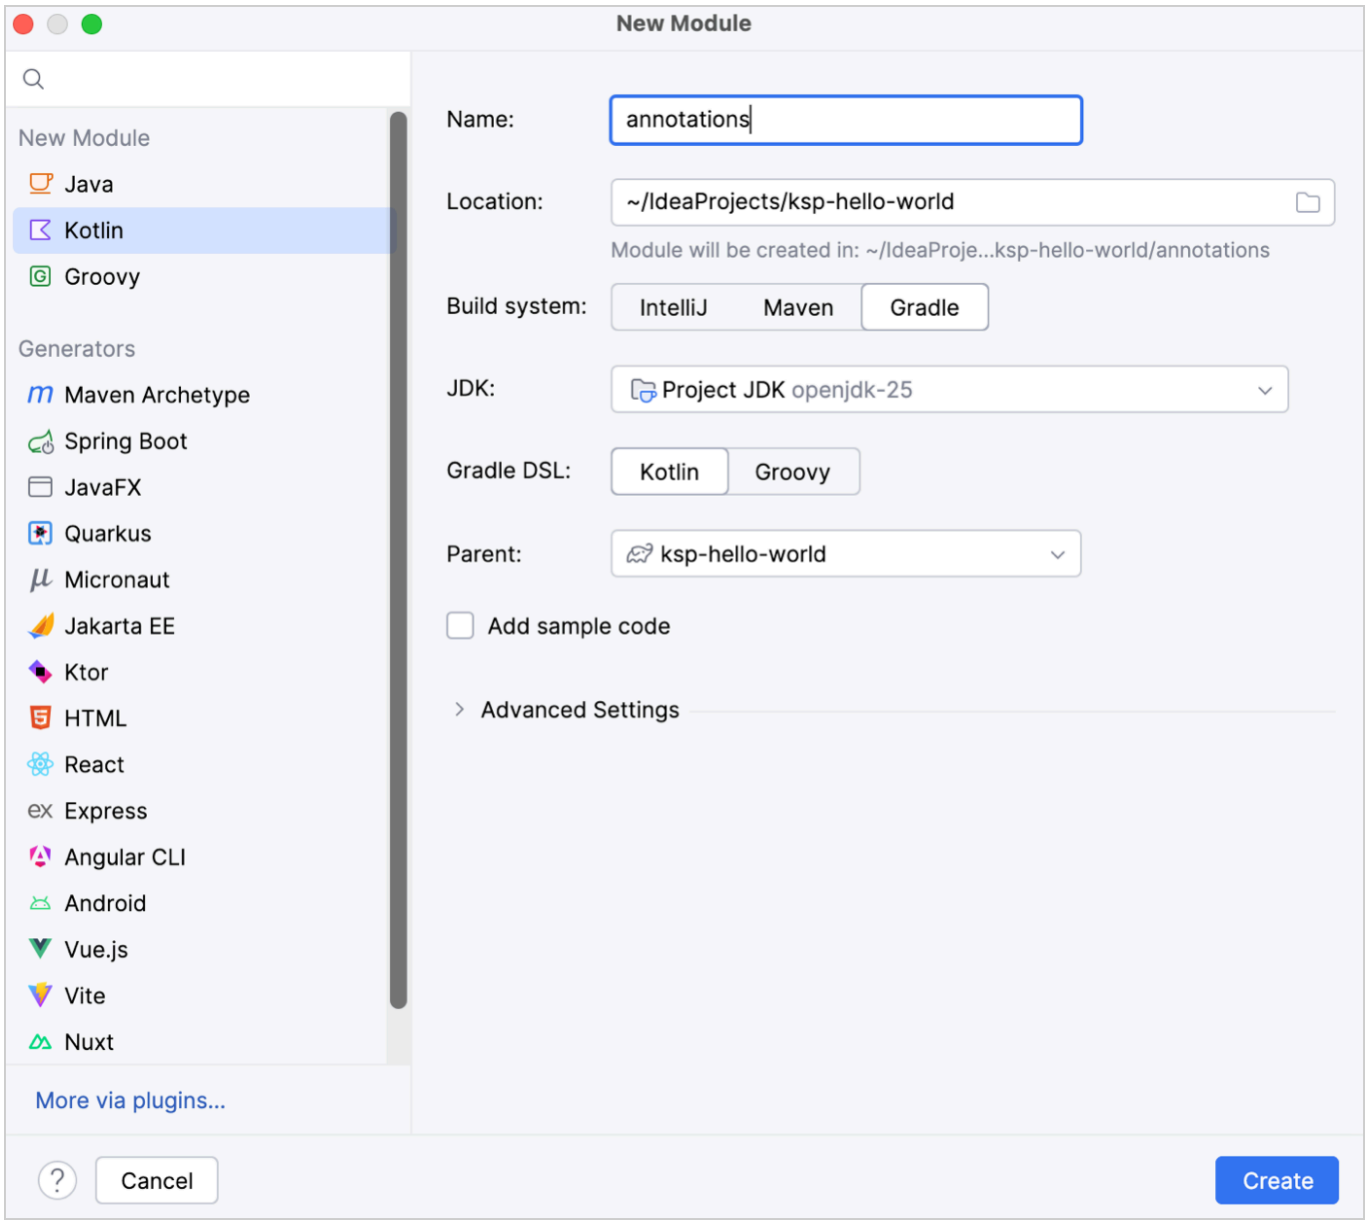
4. Add the KSP plugin to the `build.gradle(.kts)` file:

Kotlin

```kotlin
// build.gradle.kts

plugins {
    kotlin("jvm") version "2.4.20"
    id("com.google.devtools.ksp") version "2.3.10" apply false
}
```

Groovy



```
// build.gradle

plugins {
    id 'org.jetbrains.kotlin.jvm' version '2.4.20'
    id 'com.google.devtools.ksp' version '2.3.10' apply false
}
```

Create an annotation

Create a new module at the root of the project and declare an annotation:

1. Select **File** | **New** | **Module**.
2. In the list on the left, select **Kotlin**.
3. Specify the following fields and click **create**:
   - **Name**: annotations
   - **Build system**: Gradle

Creating a new module

4. In the module, create a `HelloWorldAnnotation.kt` file and declare an annotation called `HelloWorldAnnotation`:

```
// annotations/src/main/kotlin/com/example/annotations/HelloWorldAnnotation.kt

package com.example.annotations

annotation class HelloWorldAnnotation
```

Create and register a processor

1. Create another module at the root of the project called **processor**.
2. Add the KSP API and the annotation you declared as dependencies in the module's `build.gradle(.kts)` file:

Kotlin

```kotlin
// processor/build.gradle.kts

plugins {
    kotlin("jvm")
}

dependencies {
    implementation(project(":annotations"))
    implementation("com.google.devtools.ksp:symbol-processing-api:2.3.6")
}
```

Groovy

```groovy
// processor/build.gradle

plugins {
    id 'org.jetbrains.kotlin.jvm'
}

dependencies {
    implementation project ':annotations'
    implementation 'com.google.devtools.ksp:symbol-processing-api:2.3.6'
}
```

3. In the processor module, create a new `HelloWorldProcessor.kt` file and add the following code:

```kotlin
// processor/src/main/kotlin/HelloWorldProcessor.kt

class HelloWorldProcessor(val codeGenerator: CodeGenerator) : SymbolProcessor {
    // 1️⃣ process() function
    override fun process(resolver: Resolver): List<KSAnnotated> {
        resolver
            .getSymbolsWithAnnotation("com.example.annotations.HelloWorldAnnotation")
            .filter { it.validate() }
            .filterIsInstance<KSFunctionDeclaration>()
            .forEach { it.accept(HelloWorldVisitor(), Unit) }

        return emptyList()
    }

    // 2️⃣ Visitor
    inner class HelloWorldVisitor : KSVisitorVoid() {
        override fun visitFunctionDeclaration(function: KSFunctionDeclaration, data: Unit) {
            createNewFileFrom(function).use { file ->
                file.write(
                    """
                        fun helloWorld(): Unit {
                            println("Hello world from function generated by KSP")
                        }
                    """.trimIndent()
                )
            }
        }
    }

    // 3️⃣ createNewFileFrom() function
    private fun createNewFileFrom(function: KSFunctionDeclaration): OutputStream {
        return codeGenerator.createNewFile(
            dependencies = createDependencyOn(function),
            packageName = "",
            fileName = "GeneratedHelloWorld"
        )
    }

    // 3️⃣ createDependencyOn() function
    private fun createDependencyOn(function: KSFunctionDeclaration): Dependencies {
        return Dependencies(aggregating = false, function.containingFile!!)
    }
}

// Utility function for writing string to OutputStream
fun OutputStream.write(string: String): Unit {
    this.write(string.toByteArray())
}
```

Add the imports that are suggested by the IDE. Make sure to import the `Resolver` and `Dependencies` classes from `com.google.devtools.ksp.processing`. Alternatively, copy these lines at the top of `HelloWorldProcessor.kt`:

```
// processor/src/main/kotlin/HelloWorldProcessor.kt

import com.google.devtools.ksp.processing.CodeGenerator
import com.google.devtools.ksp.processing.Dependencies
import com.google.devtools.ksp.processing.Resolver
import com.google.devtools.ksp.processing.SymbolProcessor
import com.google.devtools.ksp.symbol.KSAnnotated
import com.google.devtools.ksp.symbol.KSFunctionDeclaration
import com.google.devtools.ksp.symbol.KSVisitorVoid
import com.google.devtools.ksp.validate
import java.io.OutputStream
```

Let's go through the code:

- 1️⃣ The `process()` function contains the main logic of the processor. It gets all symbols annotated with `HelloWorldAnnotation` and calls `HelloWorldVisitor` for each one.

  The `process()` function returns a list of unprocessed symbols to process in a later round. In this example, it safely returns `emptyList()`. For more information, see Multiple round processing.

- 2️⃣ Processors traverse KSP's view of the Kotlin abstract syntax tree (AST) using visitors. Inside the `HelloWorldPocessor` class, the `HelloWorldVisitor` class is the visitor. Since the `HelloWorldAnnotation` is only used on a function, only `visitFunctionDeclaration()` is overridden.

  > ℹ️ `KSVisitorVoid` is one of the visitor classes provided by KSP that you can override and adapt. You can also create your own visitor by implementing the `KSVisitor<D, R>` interface.

- 3️⃣ `createNewFileFrom()` creates the file where KSP generates code. `createDependencyOn()` makes the output file depend on the source file where the annotation is used.

  > ℹ️ To learn more about how KSP creates and manages files, visit the source code for the `CodeGenerator` interface

4. Create a `HelloWorldProcessorProvider.kt` file. In it, declare a `HelloWorldProcessorProvider` class which inherits from `SymbolProcessorProvider`:

```
// processor/src/main/kotlin/HelloWorldProcessorProvider.kt

import com.google.devtools.ksp.processing.SymbolProcessor
import com.google.devtools.ksp.processing.SymbolProcessorEnvironment
import com.google.devtools.ksp.processing.SymbolProcessorProvider

class HelloWorldProcessorProvider : SymbolProcessorProvider {
    override fun create(environment: SymbolProcessorEnvironment): SymbolProcessor {
        return HelloWorldProcessor(environment.codeGenerator)
    }
}
```

5. Register the processor provider. In the `resources/META-INF/services` directory, create a `com.google.devtools.ksp.processing.SymbolProcessorProvider` file and add the provider's fully qualified name:

```
## processor/src/main/resources/META-
INF/services/com.google.devtools.ksp.processing.SymbolProcessorProvider

HelloWorldProcessorProvider
```

Use your processor

Now you are ready to test your processor. Follow these steps to create a client module and have your processor generate code based on an annotated element:

1. Create a module called `app` at the root of your project.
2. In the module's `build.gradle(.kts)` file:
   - Add the KSP plugin to the `plugins {}` block.
   - Add your processor and annotation to the `dependencies {}` block.

   For example:

Kotlin

```
// app/build.gradle.kts

plugins {
    kotlin("jvm")
    id("com.google.devtools.ksp")
}

dependencies {
    implementation(project(":annotations"))
    ksp(project(":processor"))
}
```

Groovy

```
// app/build.gradle

plugins {
    id 'com.google.devtools.ksp'
}

dependencies {
    implementation project (':annotations')
    ksp project (':processor')
}
```

3. In the project-level `settings.gradle(.kts)` file, ensure that all the submodules were automatically included:

Kotlin

```
// settings.gradle.kts

include("annotations")
include("app")
include("processor")
```

Groovy

```
// settings.gradle

include 'processor'
include 'annotations'
include 'app'
```

4. In the `app` module, create a `Main.kt` file and add the following code:

```
// app/src/main/kotlin/Main.kt

import com.example.annotations.HelloWorldAnnotation

@HelloWorldAnnotation
fun main() {
    helloWorld()
}
```

> The `main()` function calls `helloWorld()`, even though this function does not exist yet. Your IDE highlights `helloWorld()` as an undefined reference. This is expected: KSP generates the `helloWorld()` function when you build and run the project.

5. Run the program. You see the output of the `helloWorld()` function in your console:

```
Hello world from function generated by KSP
```

KSP generates code in the `GeneratedHelloWorld.kt` file:

```
app/build/generated/ksp/main/kotlin/GeneratedHelloWorld.kt
```

Explore the project structure

Your project's final file structure should look like this:

```
.
├── app
│   ├── build.gradle.kts
│   └── src
│       └── main
│           └── kotlin
│               └── Main.kt
├── annotations
│   ├── build.gradle.kts
│   └── src
│       └── main
│           └── kotlin
│                               └── com
│                       └── example
│                                               └── annotations
│                                                       └── HelloWorldAnnotation.kt
├── processor
│   ├── build.gradle.kts
│   └── src
│       └── main
│           ├── kotlin
│           │   ├── HelloWorldProcessor.kt
│           │   └── HelloWorldProcessorProvider.kt
│           └── resources/META-INF/services
│                               └── com.google.devtools.ksp.processing.SymbolProcessorProvider
├── build.gradle.kts
└── settings.gradle.kts
```

You might have additional files and directories.

- Find more complex, real-world examples in the KSP repository.
- Browse the list of KSP supported libraries.

Migrate from kapt to KSP

In this guide, you will learn how to migrate your annotation processors from kapt to KSP so that your project can take full advantage of Kotlin features and improve build performance.

kapt (Kotlin Annotation Processing Tool) is a useful tool that lets you use Java annotation processors in Kotlin. It works by translating Kotlin source code into Java "stubs" and then running the annotation processors on those stubs. However, this process is expensive, significantly increases build time, and loses some Kotlin-specific features in translation.

In contrast, KSP (Kotlin Symbol Processing) is an alternative to kapt designed specifically for Kotlin. KSP understands all Kotlin features and analyzes the source code directly, reducing build time.

Before you begin, check whether the processors in your project support KSP. See the list of supported libraries or consult their documentation.

KSP and kapt can run alongside each other, so you can migrate your project in stages, one library or module at a time.

Add the KSP plugin to your project

Add KSP to the `plugins {}` block in the project-level `build.gradle(.kts)` file:

Kotlin

```
plugins {
    id("com.google.devtools.ksp") version "2.3.10" apply false
}
```

Groovy

```
plugins {
    id 'com.google.devtools.ksp' version '2.3.10' apply false
}
```

To find the latest version of KSP, check the GitHub Releases.

Update your processor

Find the module that uses the processor you want to migrate. In the module's `build.gradle(.kts)` file:

1. Add KSP to the `plugins {}` block:

   Kotlin

   ```
   plugins {
       id("com.google.devtools.ksp")
   }
   ```

   Groovy

   ```
   plugins {
       id 'com.google.devtools.ksp'
   }
   ```

2. In the `dependencies {}` block, replace `kapt` with `ksp`:

Kotlin

```
dependencies {
    implementation("com.google.dagger:dagger:2.48")
    // kapt("com.google.dagger:dagger-compiler:2.48")

    // KSP processor dependency:
    ksp("com.google.dagger:dagger-compiler:2.48")
}
```

Groovy

```
dependencies {
    implementation 'com.google.dagger:dagger:2.48'
    // kapt 'com.google.dagger:dagger-compiler:2.48'

    // KSP processor dependency:
    ksp 'com.google.dagger:dagger-compiler:2.48'
}
```

For most libraries, this replacement is enough. Check each library's documentation to see if you need to make any additional changes.

Remove the kapt plugin

After migrating all your processors to KSP, you can safely remove the kapt plugin from all build files:

Kotlin

```
plugins {
   // Delete this line:
    id("org.jetbrains.kotlin.kapt")
}
```

Groovy

```
plugins {
    // Delete this line:
    id 'org.jetbrains.kotlin.kapt'
}
```

Delete any leftover kapt configurations if you have them.

KSP examples

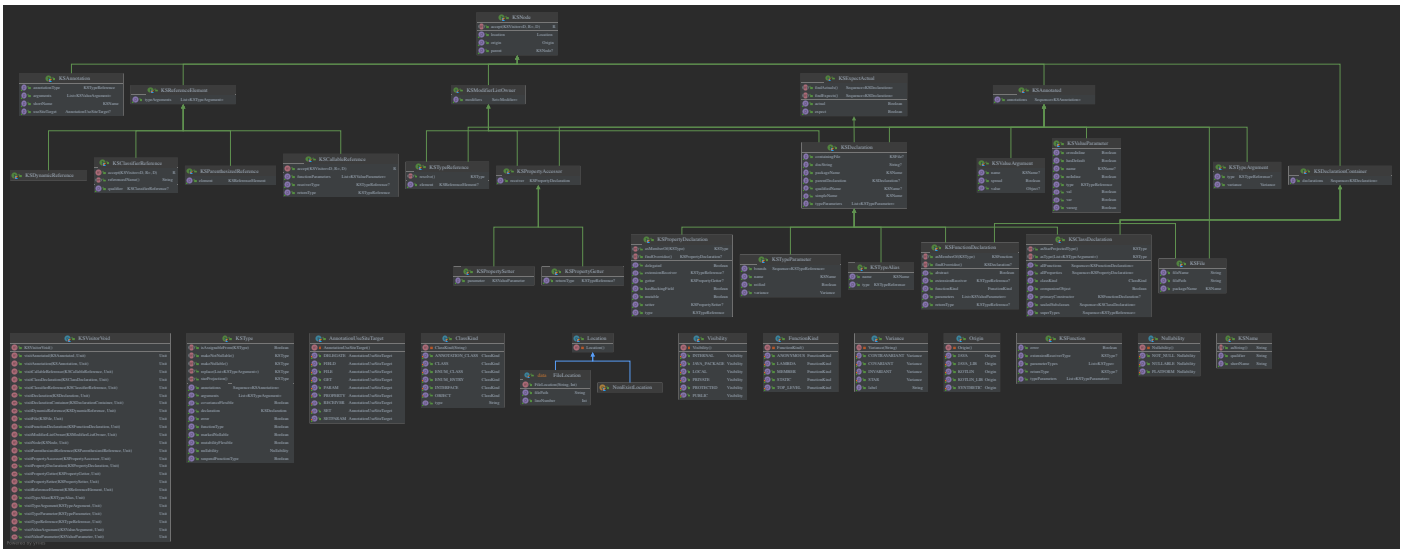
Get all member functions

```
fun KSClassDeclaration.getDeclaredFunctions(): Sequence<KSFunctionDeclaration> =
    declarations.filterIsInstance<KSFunctionDeclaration>()
```

Check whether a class or function is local

```
fun KSDeclaration.isLocal(): Boolean =
    parentDeclaration ≠ null && parentDeclaration !is KSClassDeclaration
```

Find the actual class or interface declaration that the type alias points to



```
fun KSTypeAlias.findActualType(): KSClassDeclaration {
    val resolvedType = this.type.resolve().declaration
    return if (resolvedType is KSTypeAlias) {
        resolvedType.findActualType()
    } else {
        resolvedType as KSClassDeclaration
    }
}
```

Collect suppressed names in a file annotation

```
// @file:kotlin.Suppress("Example1", "Example2")
fun KSFile.suppressedNames(): Sequence<String> = annotations
    .filter {
        it.shortName.asString() == "Suppress" &&
        it.annotationType.resolve().declaration.qualifiedName?.asString() == "kotlin.Suppress"
    }.flatMap {
        it.arguments.flatMap {
            (it.value as Array<String>).toList()
        }
    }
```

How KSP models Kotlin code

You can find the API definition in the KSP GitHub repository. The diagram shows an overview of how Kotlin is modeled in KSP:

class diagram

> See the full-sized diagram.

Type and resolution

The resolution takes most of the cost of the underlying API implementation. So type references are designed to be resolved by processors explicitly (with a few exceptions). When a *type* (such as `KSFunctionDeclaration.returnType` or `KSAnnotation.annotationType`) is referenced, it is always a `KSTypeReference`, which is a `KSReferenceElement` with annotations and modifiers.

```
interface KSFunctionDeclaration : ... {
  val returnType: KSTypeReference?
  // ...
}

interface KSTypeReference : KSAnnotated, KSModifierListOwner {
  val type: KSReferenceElement
}
```

A `KSTypeReference` can be resolved to a `KSType`, which refers to a type in Kotlin's type system.

A `KSTypeReference` has a `KSReferenceElement`, which models Kotlin's program structure: namely, how the reference is written. It corresponds to the `type` element in Kotlin's grammar.

A `KSReferenceElement` can be a `KSClassifierReference` or `KSCallableReference`, which contains a lot of useful information without the need for resolution. For example, `KSClassifierReference` has `referencedName`, while `KSCallableReference` has `receiverType`, `functionArguments`, and `returnType`.

If the original declaration referenced by a `KSTypeReference` is needed, it can usually be found by resolving to `KSType` and accessing through `KSType.declaration`. Moving from where a type is mentioned to where its class is defined looks like this:

```
val ksType: KSType = ksTypeReference.resolve()
val ksDeclaration: KSDeclaration = ksType.declaration
```

Type resolution is costly and therefore has explicit form. Some of the information obtained from resolution is already available in `KSReferenceElement`. For example, `KSClassifierReference.referencedName` can filter out

a lot of elements that are not interesting. You should resolve type only if you need specific information from `KSDeclaration` or `KSType`.

`KSTypeReference` pointing to a function type has most of its information in its element. Although it can be resolved to the family of `Function0`, `Function1`, and so on, these resolutions don't bring any more information than `KSCallableReference`. One use case for resolving function type references is dealing with the identity of the function's prototype.

Java annotation processing to KSP reference

Program elements

Java	Closest facility in KSP	Notes
`AnnotationMirror`	`KSAnnotation`	
`AnnotationValue`	`KSValueArguments`	
`Element`	`KSDeclaration` / `KSDeclarationContainer`	
`ExecutableElement`	`KSFunctionDeclaration`	
`PackageElement`	`KSFile`	KSP doesn't model packages as program elements
`Parameterizable`	`KSDeclaration`	
`QualifiedNameable`	`KSDeclaration`	
`TypeElement`	`KSClassDeclaration`	
`TypeParameterElement`	`KSTypeParameter`	
`VariableElement`	`KSValueParameter` / `KSPropertyDeclaration`	

Types

KSP requires explicit type resolution, so some functionalities in Java can only be carried out by `KSType` and the corresponding elements before resolution.

Java	Closest facility in KSP	Notes
`ArrayType`	`KSBuiltIns.arrayType`	
`DeclaredType`	`KSType` / `KSClassifierReference`	
`ErrorType`	`KSType.isError`	
`ExecutableType`	`KSType` / `KSCallableReference`	
`IntersectionType`	`KSType` / `KSTypeParameter`	
`NoType`	`KSType.isError`	N/A in KSP
`NullType`		N/A in KSP
`PrimitiveType`	`KSBuiltIns`	Not exactly same as primitive type in Java
`ReferenceType`	`KSTypeReference`	
`TypeMirror`	`KSType`	
`TypeVariable`	`KSTypeParameter`	
`UnionType`	N/A	Kotlin has only one type per catch block. `UnionType` is also not observable by even Java annotation processors
`WildcardType`	`KSType` / `KSTypeArgument`	

Misc

Java	Closest facility in KSP	Notes
`Name`	`KSName`	
`ElementKind`	`ClassKind` / `Function Kind`	
`Modifier`	`Modifier`	
`NestingKind`	`ClassKind` / `Function Kind`	
`AnnotationValueVisitor`		
`ElementVisitor`	`KSVisitor`	
`AnnotatedConstruct`	`KSAnnotated`	
`TypeVisitor`		
`TypeKind`	`KSBuiltIns`	Some can be found in builtins, otherwise check `KSClassDeclaration` for `DeclaredType`
`ElementFilter`	`Collection.filterIsInstance`	
`ElementKindVisitor`	`KSVisitor`	
`ElementScanner`	`KSTopDownVisitor`	
`SimpleAnnotationValueVisitor`		Not needed in KSP
`SimpleElementVisitor`	`KSVisitor`	
`SimpleTypeVisitor`		
`TypeKindVisitor`		

Java	Closest facility in KSP	Notes
`Types`	`Resolver` / `utils`	Some of the `utils` are also integrated into symbol interfaces
`Elements`	`Resolver` / `utils`	

Details

See how functionalities of Java annotation processing API can be carried out by KSP.

AnnotationMirror

Java	KSP equivalent
`getAnnotationType`	`ksAnnotation.annotationType`
`getElementValues`	`ksAnnotation.arguments`

AnnotationValue

Java	KSP equivalent
`getValue`	`ksValueArgument.value`

Element

Java	KSP equivalent
`asType`	`ksClassDeclaration.asType(...)` is available for `KSClassDeclaration` only. Type arguments need to be supplied.
`getAnnotation`	To be implemented
`getAnnotationMirrors`	`ksDeclaration.annotations`
`getEnclosedElements`	`ksDeclarationContainer.declarations`
`getEnclosingElements`	`ksDeclaration.parentDeclaration`

Java	KSP equivalent
`getKind`	Type check and cast following `ClassKind` or `FunctionKind`
`getModifiers`	`ksDeclaration.modifiers`
`getSimpleName`	`ksDeclaration.simpleName`

ExecutableElement

Java	KSP equivalent
`getDefaultValue`	To be implemented
`getParameters`	`ksFunctionDeclaration.parameters`
`getReceiverType`	`ksFunctionDeclaration.parentDeclaration`
`getReturnType`	`ksFunctionDeclaration.returnType`
`getSimpleName`	`ksFunctionDeclaration.simpleName`
`getThrownTypes`	Not needed in Kotlin
`getTypeParameters`	`ksFunctionDeclaration.typeParameters`
`isDefault`	Check whether parent declaration is an interface or not
`isVarArgs`	`ksFunctionDeclaration.parameters.any { it.isVarArg }`

Parameterizable

Java	KSP equivalent
`getTypeParameters`	`ksFunctionDeclaration.typeParameters`

QualifiedNameable

Java	KSP equivalent
`getQualifiedName`	`ksDeclaration.qualifiedName`

TypeElement

Java	KSP equivalent
`getEnclosedElements`	`ksClassDeclaration.declarations`
`getEnclosingElement`	`ksClassDeclaration.parentDeclaration`

`getInterfaces`	`// Should be able to do without resolution`
	`ksClassDeclaration.superTypes`
	`.map { it.resolve() }`
	`.filter { (it?.declaration as? KSClassDeclaration)?.classKind == ClassKind.INTERFACE }`

`getNestingKind`	Check `KSClassDeclaration.parentDeclaration` and `inner` modifier
`getQualifiedName`	`ksClassDeclaration.qualifiedName`
`getSimpleName`	`ksClassDeclaration.simpleName`

`getSuperclass`	`// Should be able to do without resolution`
	`ksClassDeclaration.superTypes`
	`.map { it.resolve() }`
	`.filter { (it?.declaration as? KSClassDeclaration)?.classKind == ClassKind.CLASS }`

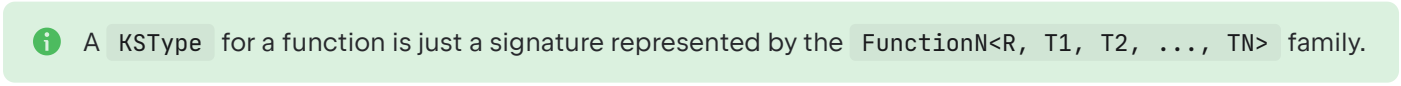
`getTypeParameters`	`ksClassDeclaration.typeParameters`

TypeParameterElement

Java	KSP equivalent
`getBounds`	`ksTypeParameter.bounds`
`getEnclosingElement`	`ksTypeParameter.parentDeclaration`
`getGenericElement`	`ksTypeParameter.parentDeclaration`

VariableElement

Java	KSP equivalent
`getConstantValue`	To be implemented
`getEnclosingElement`	`ksValueParameter.parentDeclaration`
`getSimpleName`	`ksValueParameter.simpleName`



ArrayType

Java	KSP equivalent
`getComponentType`	`ksType.arguments.first()`

DeclaredType

Java	KSP equivalent
`asElement`	`ksType.declaration`
`getEnclosingType`	`ksType.declaration.parentDeclaration`
`getTypeArguments`	`ksType.arguments`

ExecutableType

A `KSType` for a function is just a signature represented by the `FunctionN<R, T1, T2, ..., TN>` family.

Java	KSP equivalent
`getParameterTypes`	`ksType.declaration.typeParameters`, `ksFunctionDeclaration.parameters.map { it.type }`
`getReceiverType`	`ksFunctionDeclaration.parentDeclaration.asType(...)`
`getReturnType`	`ksType.declaration.typeParameters.last()`
`getThrownTypes`	Not needed in Kotlin

Java	KSP equivalent
`getTypeVariables`	`ksFunctionDeclaration.typeParameters`

IntersectionType

Java	KSP equivalent
`getBounds`	`ksTypeParameter.bounds`

TypeMirror

Java	KSP equivalent
`getKind`	Compare with types in `KSBuiltIns` for primitive types, `Unit` type, otherwise declared types

TypeVariable

Java	KSP equivalent
`asElement`	`ksType.declaration`
`getLowerBound`	To be decided. Only needed if capture is provided and explicit bound checking is needed.
`getUpperBound`	`ksTypeParameter.bounds`

WildcardType

Java	KSP equivalent
`getExtendsBound`	`if (ksTypeArgument.variance == Variance.COVARIANT) ksTypeArgument.type else null`
`getSuperBound`	`if (ksTypeArgument.variance == Variance.CONTRAVARIANT) ksTypeArgument.type else null`

Elements

Java	KSP equivalent
`getAllAnnotationMirrors`	`KSDeclarations.annotations`
`getAllMembers`	`getAllFunctions` , `getAllProperties` is to be implemented
`getBinaryName`	To be decided, see Java Specification
`getConstantExpression`	There is constant value, not expression
`getDocComment`	To be implemented
`getElementValuesWithDefaults`	To be implemented
`getName`	`resolver.getKSNameFromString`
`getPackageElement`	Package not supported, while package information can be retrieved. Operation on package is not possible for KSP
`getPackageOf`	Package not supported
`getTypeElement`	`Resolver.getClassDeclarationByName`
`hides`	To be implemented
`isDeprecated`	`KsDeclaration.annotations.any { it.annotationType.resolve()!!.declaration.qualifiedName!!.asString() == Deprecated::class.qualifiedName }`
`overrides`	`KSFunctionDeclaration.overrides` / `KSPropertyDeclaration.overrides` (member function of respective class)
`printElements`	KSP has basic `toString()` implementation on most classes

Types

Java	KSP equivalent
`asElement`	`ksType.declaration`
`asMemberOf`	`resolver.asMemberOf`
`boxedClass`	Not needed
`capture`	To be decided
`contains`	`KSType.isAssignableFrom`
`directSuperTypes`	`(ksType.declaration as KSClassDeclaration).superTypes`
`erasure`	`ksType.starProjection()`
`getArrayType`	`ksBuiltIns.arrayType.replace(...)`
`getDeclaredType`	`ksClassDeclaration.asType`
`getNoType`	`ksBuiltIns.nothingType` / `null`
`getNullType`	Depending on the context, `KSType.markNullable` could be useful
`getPrimitiveType`	Not needed, check for `KSBuiltins`
`getWildcardType`	Use `Variance` in places expecting `KSTypeArgument`
`isAssignable`	`ksType.isAssignableFrom`
`isSameType`	`ksType.equals`
`isSubsignature`	`functionTypeA == functionTypeB` / `functionTypeA == functionTypeB.starProjection()`
`isSubtype`	`ksType.isAssignableFrom`
`unboxedType`	Not needed

Incremental processing

KSP supports incremental processing: KSP reprocesses a file only when one or more of its dependencies change. This avoids unnecessary reprocessing and therefore reduces compilation time.

Incremental processing is enabled by default. You can disable it when troubleshooting or when you need to force a full rebuild. To disable it, add the following line to your `gradle.properties` file:

```
ksp.incremental=false
```

Dirty files

A file is considered *dirty* (needing to be reprocessed) if it is either directly modified by a developer or indirectly affected by changes in other dirty files.

To determine which sources are dirty, KSP relies on processors, which associate generated outputs with their corresponding input sources. KSP uses these associations to identify the sources that must be reprocessed when a change occurs.

KSP requires only a minimal set of root sources. Processors use these sources as entry points to navigate the code structure.

A root source is a source file whose symbols are obtained directly from any of the following methods:

- `Resolver.getAllFiles()`
- `Resolver.getSymbolsWithAnnotation()`
- `Resolver.getClassDeclarationByName()`
- `Resolver.getDeclarationsFromPackage()`

A processor can obtain additional symbols from other source files by resolving information from a root source. KSP automatically tracks these dependencies.

When generating an output, the processor must declare the root sources that contribute to that output. KSP uses those root sources and their tracked dependencies to determine when the output needs to be regenerated.

Use the `CodeGenerator` interface to create output files and associate inputs with outputs. For more information, see `CodeGenerator.kt` in the source code.

Aggregating and isolating outputs

KSP classifies generated outputs into two types: aggregating and isolating.

Unlike Gradle annotation processing, KSP applies the categorization to individual outputs rather than entire processors.

Aggregating

Aggregating outputs can be affected by changes in any source file, except for removals that do not impact other files.

Any input change triggers a rebuild of all aggregating outputs and reprocessing of all corresponding registered, new, or modified source files.

For example, an output that collects all symbols with a particular annotation is aggregating.

Isolating

Isolating outputs depend only on their specified sources.

Changes to other sources do not affect the output. Multiple source files can be associated with a single output.

For example, a generated class that is dedicated to an interface it implements is isolating.

Dirtiness propagation

KSP propagates dirtiness in the following ways:

1. By **resolution tracing**: Type resolution is the only way to traverse from one file to another. When a processor resolves a type reference (explicitly or implicitly), KSP considers dependencies between the file containing the reference and any file that defines a symbol affecting that resolution. As a result, a change in a resolved symbol may mark the referencing file as dirty.
2. By **input-output correspondence**: If a source file is changed or affected, all other source files that share generated outputs with it are also marked as affected. This groups related files into equivalence classes based on shared outputs.

> Rules (1) and (2) can trigger each other repeatedly. For example, rule (1) can trigger rule (2), which can then trigger rule (1) again.

Implementation

Dependencies are determined by the many-to-many relationship between input and output files.

This is how KSP determines which files need to be reprocessed:

- If an input file is changed, it will always be reprocessed.

  Why? If an input is changed, new information can be introduced. Processors need to run again with the input.

- If an input file is changed and is associated with an output, then all other input files associated with the same output will also be reprocessed. This happens repeatedly until there is no new dirty file.

  Why? An output is made out of a set of inputs. Processors may need all the inputs to regenerate the output.

- If an unchanged input file isn't associated with any aggregating outputs, it won't be reprocessed.

  Why? This file can't affect any outputs because it is unchanged and isn't associated with an aggregating output. It won't be reprocessed unless one of the above rules applies.

For example, consider a project with the following structure:

```
.
├── src
│   ├── sourceA.kt
│   └── sourceB.kt
└── generated
    ├── outputA
    └── outputB
```

A processor:

1. reads `sourceA`.

2. generates `outputA`.
3. reads `sourceB`.
4. generates `outputB`.

When `sourceA` changes:

- If `outputB` is aggregating, KSP reprocesses both `sourceA` and `sourceB`.
- If `outputB` is isolating, KSP reprocesses `sourceA` only.

If `sourceC` is added:

- If `outputB` is aggregating, KSP reprocesses `sourceC` and `sourceB`.
- If `outputB` is isolating, KSP reprocesses only `sourceC`.

If either `sourceA` or `sourceB` is removed, KSP doesn't need to reprocess any files.

Example processor

The following project contains classes `A` and `B`, where `A` extends `B`:

```
// A.kt
@Interesting
class A : B()

// B.kt
open class B

// Example1Processor.kt
class Example1Processor : SymbolProcessor {
   override fun process(resolver: Resolver) {
       val declA = resolver.getSymbolsWithAnnotation("Interesting").first() as KSClassDeclaration
       val declB = declA.superTypes.first().resolve().declaration
       // B.kt isn't required, because it can be deduced as a dependency by KSP
       val dependencies = Dependencies(aggregating = true, declA.containingFile!!)
       // outputForA.kt
       val outputName = "outputFor${declA.simpleName.asString()}"
       // outputForA depends on A.kt and B.kt
       val output = codeGenerator.createNewFile(dependencies, "com.example", outputName, "kt")
       output.write("// $declA : $declB\n".toByteArray())
       output.close()
   }
   // ...
}
```

To generate `outputForA`, the processor:

1. gets A by calling `Resolver.getSymbolsWithAnnotation`.
2. gets B by calling `KSClassDeclaration.superTypes` on A.

KSP tracks this relationship through resolution tracing and automatically records `B` as a dependency of `A`. Therefore, you don't need to explicitly declare `B.kt` as a dependency of `outputForA`.

Reporting bugs

If you encounter any error that occurs only when incremental processing is enabled, create an issue in the GitHub repository and attach the relevant log files.

1. Enable incremental processing logs by adding the following line to `gradle.properties`:

   ```
   ksp.incremental.log=true
   ```

2. Perform a clean build that completes successfully.
3. Save the generated log files by copying them to another location:
   - `build/kspCaches/<source set>/logs/kspDirtySet.log`
   - `build/kspCaches/<source set>/logs/kspSourceToOutputs.log`
4. Modify a source file that triggers the issue and run the build again.
5. Attach the log files from both the successful build and the build that reproduces the issue to the GitHub issue.

Visualizing the symbol dependency graph

To help debug incremental processing, KSP can generate a Graphviz DOT file that visualizes the symbol dependency graph starting from a specified symbol.

Enable incremental logging and specify the fully qualified name of the symbol to use as the starting point for visualizing the graph:

```
ksp.incremental.log=true
ksp.incremental.log.graph.origin=<fully-qualified-name>
```

If you're using KSP from the command line, add the following options:

```
-incremental-log=true -incremental-log.graph.origin=<fully-qualified-name>
```

The DOT file is generated in the `logs` directory.

Multiple-round processing

KSP supports multiple-round processing, or processing files over multiple rounds. The output from each processing round is used as additional input in each subsequent round.

To use multiple-round processing, return deferred symbols from `SymbolProcessor.process()` as a `List<KSAnnotated>`. KSP processes these symbols in the next round.

To defer invalid symbols, filter them with `KSAnnotated.validate()`, for example:

```
override fun process(resolver: Resolver): List<KSAnnotated> {
    val symbols = resolver.getSymbolsWithAnnotation("com.example.annotation.Builder")
    val result = symbols.filter { !it.validate() }
    symbols
        .filter { it is KSClassDeclaration && it.validate() }
        .map { it.accept(BuilderVisitor(), Unit) }
    return result
}
```

Multiple-round processing ends when an entire round generates no new files. If deferred symbols remain unprocessed, KSP logs an error for each processor with remaining deferred symbols.

Deferring symbols to the next round

Processors can defer symbols to a later round when additional information is required from other processors. A processor can continue deferring a symbol across multiple rounds until the required information becomes available. Once the information is available, the processor can process the symbol.

Defer symbols only when:

- Additional information is required before the symbol can be processed.
- The symbol originates from source code.

> Never defer symbols from the classpath. KSP filters out classpath symbols automatically.

For example, a processor that generates a builder for an annotated class might require all constructor parameter types to resolve to concrete types. In the first round, one of the parameter types might not be resolvable. In a later round, it can become resolvable because of files generated in the meantime. The processor can then process the class.

Validating symbols

Validation is a convenient way to determine whether to defer a symbol to a later round. A processor should define the information required to process a symbol correctly.

> Validation often requires type resolution, which can be expensive. Check only the information required to process the symbol.

Default validation behavior might not be suitable for all use cases. To customize validation, use `KSValidateVisitor` and provide a `predicate` lambda that selects the symbols to validate.

When implementing custom validation, use `KSType.isError` to determine whether a type is valid. If `isError` is `true`, KSP could not resolve the type. Use this information to decide whether to defer processing to a later round.

Accessing files and symbols

Both newly generated files and existing files are accessible through a `Resolver`.

KSP provides two APIs for accessing files:

- `Resolver.getAllFiles()` returns a list of both previously existing and newly generated files.
- `Resolver.getNewFiles()` returns only the files generated in the previous round.

Use `Resolver.getSymbolsWithAnnotation()` as the primary entry point for obtaining relevant symbols.

In each round, `Resolver.getSymbolsWithAnnotation()` returns only symbols from newly generated files and symbols deferred from the previous round. This helps avoid unnecessary reprocessing.

Processor instantiation

KSP creates a processor instance only once. You can store information in the processor instance and reuse it across multiple rounds.

However, not all KSP symbols can be reused across rounds. Symbol resolution results can change when processors generate new files, which can affect the validity of previously resolved symbols.

> Use only the `Resolver` instance passed to the processor in the current round. Do not store a `Resolver` and reuse it across rounds.

Error and exception handling

Errors

A processor reports an error by calling `KSPLogger.error()`.

When a processor reports an error, KSP calls `SymbolProcessor.onError()` instead of `SymbolProcessor.finish()`. Processing stops after the current round completes.

Other processors continue processing normally during that round. KSP handles errors only after all processors finish the current round.

Exceptions

KSP distinguishes between exceptions thrown by KSP and exceptions thrown by processors. Both types terminate processing immediately and are logged as errors through `KSPLogger`.

> Report exceptions thrown by KSP to the KSP developers for investigation. Create an issue in the KSP issue tracker.

At the end of a round in which an error or exception occurs, KSP calls `SymbolProcessor.onError()` on all processors. `SymbolProcessor` provides a default no-op implementation of `onError()`. Override this method to implement custom error-handling logic.

KSP with Kotlin Multiplatform

Here you'll learn how to use Kotlin Symbol Processing (KSP) in a Kotlin Multiplatform project. For a quick start, see an example of a multiplatform project with several targets using KSP in the source repository. The processor in this example generates a `Foo` class used by the project.

Add KSP to a multiplatform project

In the `build.gradle.kts` file of the client module (the module that uses the processor), add the appropriate KSP processor dependency for each target that requires symbol processing:

```
dependencies {
  add("ksp<Target>", <processor>)
}
```

- `<Target>` is one of the targets used in your multiplatform project.

  > For a full list of targets, see Multiplatform Gradle DSL reference and Kotlin/Native supported targets.

- `<processor>` is a Gradle project path. It can be:
  - a specific directory in your project that contains the logic for your symbol processor:

    ```
    add("kspJvm", project(":local-processor"))
    ```

  - an external processor such as Room:

    ```
    add("kspJvm", "androidx.room:room-compiler:2.6.1")
    ```

> Since KSP 2, the catch-all `ksp(...)` configuration is deprecated. Configure each target explicitly to avoid running processors where they are not needed.

Use multiple processors in a single target

You can add more than one processor to a target:

Kotlin

```
add("kspAndroid", project(":test-processor"))
add("kspAndroid", "androidx.room:room-compiler:2.6.1")
```

Groovy

```
add('kspAndroid', project(':test-processor'))
add('kspAndroid', 'androidx.room:room-compiler:2.6.1')
```

Use the same processor in multiple targets

You can add the same processor to more than one target:

Kotlin

```
add("kspIosX64", project(":test-processor"))
add("kspIosArm64", project(":test-processor"))
add("kspIosSimulatorArm64", project(":test-processor"))
```

Groovy

```
add('kspIosX64', project(':test-processor'))
add('kspIosArm64', project(':test-processor'))
add('kspIosSimulatorArm64', project(':test-processor'))
```

If you have many iOS targets, you can avoid repetition by looping:

Kotlin

```
kotlin.targets.filter { it.name.startsWith("ios") }.forEach { target →
    add(
        "ksp${target.name.replaceFirstChar { it.uppercaseChar() }}",
        project(":test-processor")
    )
}
```

Groovy

```
kotlin.targets.filter { it.name.startsWith("ios") }.forEach { target →
    add(
        "ksp${target.name.replaceFirstChar { it.uppercaseChar() }}",
        project(":test-processor")
    )
}
```

Configure KSP for test compilations

To run KSP during test compilation, add the processor to the corresponding test configurations:

Kotlin

```
add("kspJvmTest", project(":test-processor"))
add("kspJsTest", project(":test-processor"))
add("kspIosX64Test", project(":test-processor"))
```

Groovy

```
add('kspJvmTest', project(':test-processor'))
add('kspJsTest', project(':test-processor'))
add('kspIosX64Test', project(':test-processor'))
```

For Android host and device tests, KSP derives configuration names from the corresponding source set names:

Kotlin

```
add("kspAndroidHostTest", project(":test-processor"))
add("kspAndroidDeviceTest", project(":test-processor"))
```

Groovy

```
add('kspAndroidHostTest', project(':test-processor'))
add('kspAndroidDeviceTest', project(':test-processor'))
```

Find KSP configuration names

KSP derives configuration names from the Kotlin Multiplatform source sets. To view the complete list of KSP configurations for a module, run:

```
./gradlew :<your-module-name>:dependencies | grep ksp
```

Look for the configuration names that correspond to your target source sets.

Compilation and processing

In a multiplatform project, Kotlin creates a separate compilation for each target and source set, such as `main` and `test`. For each Kotlin compilation task with one or more configured KSP processors, KSP creates a corresponding symbol processing task.

The example project defines six targets. Each target has `main` and `test` compilations, resulting in the following compilation and symbol processing tasks:

- **JVM**: `jvmMain` and `jvmTest`
- **JS**: `jsMain` and `jsTest`
- **LinuxX64**: `linuxX64Main` and `linuxX64Test`
- **AndroidNativeX64**: `androidNativeX64Main` and `androidNativeX64Test`
- **AndroidNativeArm64**: `androidNativeArm64Main` and `androidNativeArm64Test`
- **MingwX64**: `mingwX64Main` and `mingwX64Test`

In the example's `workload/build.gradle.kts` file, KSP dependencies are declared for the following configurations:

- `kspJvm` and `kspJvmTest`
- `kspJs` and `kspJsTest`
- `kspAndroidNativeX64` and `kspAndroidNativeX64Test`
- `kspAndroidNativeArm64` and `kspAndroidNativeArm64Test`
- `kspLinuxX64`
- `kspMingwX64`

KSP creates a symbol processing task for each configuration where a KSP dependency is declared. In this example, the project creates at least 12 Kotlin compilation tasks and 10 symbol processing tasks. The remaining compilations don't have corresponding KSP tasks because KSP isn't configured for them.

Running KSP from the command line

Most projects use KSP through the Gradle plugin, which runs KSP automatically during compilation. You can use KSP from the command line but it's normally only used when you're integrating with other build systems, developing processors, testing, or debugging.

Since KSP is a JVM application, use the `java` command to launch KSP from the command line. Provide the classpath and any necessary arguments:

```
java -cp <classpath> <mainclass> <options> <processor>
```

Argument	Description
`<classpath>`	Path to KSP runtime JARs and their dependencies.
`<mainclass>`	One of the platform-specific KSP entry points.
`<options>`	Command-line options for KSP.
`<processor>`	Path to the processor JAR.

Classpath

Unlike the Gradle plugin, the `java` command doesn't resolve dependencies automatically. You must provide the KSP runtime JARs and their dependencies on the classpath.

Download `artifacts.zip` from the KSP release page. The archive contains the required KSP JAR files:

- `symbol-processing-aa-2.3.10.jar`
- `symbol-processing-common-deps-2.3.10.jar`
- `symbol-processing-api-2.3.10.jar`

You must also include the following runtime dependencies from the Maven Repository:

- `kotlin-stdlib-2.4.20.jar`
- `kotlinx-coroutines-core-jvm-1.11.0.jar`

Main class

Because KSP is a JVM application, you must specify the main class to launch. KSP provides a different entry point for each supported platform:

Entry point	Platforms
`KSPJvmMain`	Kotlin/JVM and Android
`KSPJsMain`	Kotlin/JS
`KSPNativeMain`	Kotlin/Native targets, such as iOS, macOS, Linux, and Windows.
`KSPCommonMain`	Common compilations in Kotlin Multiplatform projects.

When launching KSP with `java`, specify the fully qualified class name. For example:

```
java -cp <classpath> com.google.devtools.ksp.cmdline.KSPJvmMain <options> <processor>
```

The following example uses `KSPJvmMain` to run KSP for a JVM target:

```
java -cp \
symbol-processing-aa-2.3.10.jar:symbol-processing-common-deps-2.3.10.jar:symbol-processing-api-
2.3.10.jar:kotlin-stdlib-2.3.20.jar:kotlinx-coroutines-core-jvm-1.10.2.jar \
com.google.devtools.ksp.cmdline.KSPJvmMain \
-language-version=2.0 \
-api-version=2.0 \
-jvm-target=11 \
-module-name=main \
-source-roots=project_dir/src/kotlin/main \
-project-base-dir=project_dir/ \
-output-base-dir=project_dir/build/ \
-caches-dir=project_dir/build/caches/ \
-class-output-dir=project_dir/build/out/main/classes \
-kotlin-output-dir=project_dir/build/out/main/kotlin/ \
-java-output-dir=project_dir/build/out/main/java/ \
-resource-output-dir=project_dir/build/out/main/res/ \
path/to/processor.jar
```

Options

KSP requires the following options when running from the command line:

Option	Description
`-language-version=<version>`	The Kotlin language version used in the project.
`-api-version=<version>`	The Kotlin API version.
`-jvm-target=<version>`	The target JVM version.
`-module-name=<name>`	The module name.
`-source-roots=<paths>`	The source root directories. Use a colon-separated list for multiple directories.
`-project-base-dir=<path>`	The project root directory.
`-output-base-dir=<path>`	The base directory for KSP output.
`-caches-dir=<path>`	The directory for KSP caches.
`-java-output-dir=<path>`	The directory for generated Java files.
`-class-output-dir=<path>`	The directory for generated class files.

Option	Description
`-kotlin-output-dir=<path>`	The directory for generated Kotlin files.
`-resource-output-dir=<path>`	The directory for generated resources.
`<processor>`	The processor classpath.

Other useful options

- `-libraries=<path>` : The classpath used to resolve dependencies referenced by the source files. Typically the module's compile classpath.
- `-jdk-home=<path>` : The JDK home directory. Use when the processor resolves Java symbols and requires access to the Java standard library.
- `-friends=<path>` : The classpath of the current module's friend modules. This is typically the module's friend classpath. For more information, see Friend modules.

> KSP also supports the `-Dksp.logging` JVM system property, which sets the logging level. Valid values are `error` , `warn` or `warning` , `info` , and `debug` . The default value is `warn` . KSP treats unsupported values as `warn` .

To see the full list of options, run the following command:

```
java -cp <classpath> <mainclass> -h
```

KSP FAQ

Why KSP?

KSP has several advantages over kapt:

- It is faster.
- The API is more fluent for Kotlin users.
- It supports multiple round processing on generated Kotlin sources.
- It is being designed with multiplatform compatibility in mind.

Why is KSP faster than kapt?

kapt has to parse and resolve every type reference in order to generate Java stubs, whereas KSP resolves references on-demand. Delegating to javac also takes time.

Additionally, KSP's incremental processing model has a finer granularity than just isolating and aggregating. It finds more opportunities to avoid reprocessing everything. Also, because KSP traces symbol resolutions

dynamically, a change in a file is less likely to pollute other files and therefore the set of files to be reprocessed is smaller. This is not possible for kapt because it delegates processing to javac.

Is KSP Kotlin-specific?

KSP can process Java sources as well. The API is unified, meaning that when you parse a Java class and a Kotlin class, you get a unified data structure in KSP.

How to upgrade KSP?

KSP has API and implementation. The API rarely changes and is backward compatible: there can be new interfaces, but old interfaces never change. The implementation is tied to a specific compiler version. With the new release, the supported compiler version can change.

Processors only depend on API and therefore are not tied to compiler versions. However, users of processors need to bump KSP version when bumping the compiler version in their project. Otherwise, the following error will occur:

```
ksp-a.b.c is too old for kotlin-x.y.z. Please upgrade ksp or downgrade kotlin-gradle-plugin
```

Users of processors don't need to bump processor's version because processors only depend on API.

For example, some processor is released and tested with KSP 1.0.1, which depends strictly on Kotlin 1.6.0. To make it work with Kotlin 1.6.20, the only thing you need to do is bump KSP to a version (for example, KSP 1.1.0) that is built for Kotlin 1.6.20.

Can I use a newer KSP implementation with an older Kotlin compiler?

If the language version is the same, Kotlin compiler is supposed to be backward compatible. Bumping Kotlin compiler should be trivial most of the time. If you need a newer KSP implementation, please upgrade the Kotlin compiler accordingly.

How often do you update KSP?

KSP tries to follow Semantic Versioning as close as possible. With KSP version `major.minor.patch`,

- `major` is reserved for incompatible API changes. There is no pre-determined schedule for this.
- `minor` is reserved for new features. This is going to be updated approximately quarterly.
- `patch` is reserved for bug fixes and new Kotlin releases. It's updated roughly monthly.

Usually a corresponding KSP release is available within a couple of days after a new Kotlin version is released, including the pre-releases (Beta or RC).

Besides Kotlin, are there other version requirements for libraries?

Here is a list of requirements for libraries/infrastructures:

- Android Gradle Plugin 7.1.3+
- Gradle 6.8.3+

What is KSP's future roadmap?

The following items have been planned:

- Support new Kotlin compiler
- Improve support for multiplatform. For example, running KSP on a subset of targets/sharing computations between targets.
- Improve performance. There are a bunch of optimizations to be done!
- Keep fixing bugs.

Please feel free to reach out to us in the #ksp channel in Kotlin Slack (get an invite) if you would like to discuss any ideas. Filing GitHub issues/feature requests or pull requests are also welcome!

Kotlin roadmap

Last modified on August 2026

Next update February 2027

Welcome to the Kotlin roadmap! Get a sneak peek into the priorities of the JetBrains team.

Key priorities

The goal of this roadmap is to give you the big picture. Here's a list of our key focus areas – the most important directions we are focused on delivering:

- **Language evolution**: keep Kotlin concise and expressive, prioritizing ergonomics and safety over ceremony.
- **Kotlin Multiplatform**: become the foundation for modern cross-platform apps through a solid iOS experience, mature web targets, and reliable IDE tooling.
- **Staying agnostic**: support developers no matter their tools or targets.
- **Experience of third-party ecosystem authors:** simplify the development and publication process for Kotlin libraries, tools, and frameworks.

Kotlin roadmap by subsystem

If you have any questions or feedback about the roadmap or the items on it, feel free to post them to YouTrack tickets or in the #kotlin-roadmap channel of Kotlin Slack (request an invite).

Subsystem	In focus now
Language	See the full list of Kotlin language features and proposals or follow the YouTrack issue for upcoming language features
Compiler	• 🆕 Promote Kotlin/Wasm to Stable • 🆕 Improve KAPT performance to be comparable with Java APT •

Subsystem	In focus now
	Stabilize overload resolution by lambda return type • Support K2 multiplatform incremental compilation of common code • New JVM reflection: Investigation, prototype and implementation • Kotlin/Wasm: Switch the `wasm-wasi` target of libraries to WASI Preview 2 • Kotlin/Wasm: Support the Component Model
Multiplatform	• 🆕 Improved rendering reliability and future-proof GPU support via Graphite in Skiko • 🆕 Xcode integration for Kotlin/Native debugger • 🆕 Swift Export: from Alpha to Beta • 🆕 Make Native Text Input default in Compose Multiplatform for iOS • 🆕 Native compiler caches in release mode • Unify inline semantics between stable Kotlin targets • Kotlin/JS: Improve onboarding materials for Kotlin/JS • Kotlin/JS: Compile to the modern JavaScript • Kotlin/JS: Extend possibilities for exporting Kotlin declarations to JavaScript • Enable incremental compilation of klib artifacts by default
Tooling	• 🆕 Streamline the Kotlin-on-Maven onboarding with a unified compiler-plugins bundle • 🆕 Xcode integration for Kotlin/Native debugger • 🆕 Enable Native tasks parallelization without configuration cache enabled • 🆕 Kotlin Toolchain: a single entry point into Kotlin • Kotlin/Native debugger health and performance improvements • Support for importing Swift Package Manager packages in Kotlin • Replace Karma runner with a not-deprecated alternative • Support Kotlin/JS and Kotlin/Wasm in Gradle project isolation • Design the Build tools API • Support Kotlin LSP and VS Code
Ecosystem	• 🆕 Implement first-class JPA/Hibernate support for Kotlin stdlib types • Stabilize the experimental `kotlinx.serialization` API • Improve the Lombok compiler plugin experience with Kotlin for server side • Stabilize `kotlinx.collections.immutable` • Promote `kotlinx-datetime` to Beta • Implement KDoc machine-readable representation •

Subsystem	In focus now
	New multiplatform API for the standard library: Support for Unicode and codepoints • Stabilize the `kotlinx-io` library • Introduce default warnings/errors for Kotlin functions that return non-unit values that are unused • Release Kotlin DataFrame 1.0 • Release Kandy 0.9 Ktor: • Improve authentication in Ktor • Support HTTP/3 • Add gRPC support to Ktor with a generator plugin and tutorial • Improve Ktor administration and observability Exposed: • Release Exposed DAO 2.0

- This roadmap is not an exhaustive list of all things the team is working on, only the biggest projects.
- There's no commitment to delivering specific features or fixes in specific versions.
- We will adjust our priorities as we go and update the roadmap approximately every six months.

What's changed since February 2026

Completed items

We've **completed** the following items from the previous roadmap:

- ✅ Compiler: Evolve the Power-assert plugin
- ✅ Compiler: Kotlin/Wasm: Support multi-module compilation
- ✅ Multiplatform: Swift Export: Alpha release
- ✅ Multiplatform: Implement new `TextInputService` on iOS for Compose Multiplatform
- ✅ Multiplatform: Swift 6.3 support
- ✅ Multiplatform: Stabilize Navigation3 for Compose Multiplatform
- ✅ Tooling: Smart defaults for Kotlin on Maven (mixed Java + Kotlin)
- ✅ Tooling: Release Kotlin ecosystem plugin supporting declarative Gradle
- ✅ Ecosystem: Improve Kotlin distribution UX: Add code coverage and binary compatibility validation
- ✅ Ecosystem: Introduce 18-month support window for security fixes in the standard library
- ✅ Ecosystem: Create a migration Gradle plugin for Exposed

New items

We've **added** the following items to the roadmap:

- 🆕 Compiler: Promote Kotlin/Wasm to Stable
- 🆕 Compiler: Improve KAPT performance to be comparable with Java APT
- 🆕 Multiplatform: Improved rendering reliability and future-proof GPU support via Graphite in Skiko
- 🆕 Multiplatform: Swift Export: from Alpha to Beta
- 🆕 Multiplatform: Make Native Text Input default in Compose Multiplatform for iOS
- 🆕 Multiplatform: Native compiler caches in release mode
- 🆕 Tooling: Streamline the Kotlin-on-Maven onboarding with a unified compiler-plugins bundle
- 🆕 Tooling: Xcode integration for Kotlin/Native debugger
- 🆕 Tooling: Enable Native tasks parallelization without configuration cache enabled
- 🆕 Tooling: Kotlin Toolchain: a single entry point into Kotlin
- 🆕 Ecosystem: Implement first-class JPA/Hibernate support for Kotlin stdlib types

Removed items

We've **removed** the following items from the roadmap:

- ❌ Multiplatform: Implement the next generation distribution format of multiplatform libraries
- ❌ Tooling: Improve Kotlin scripting and experience with `.gradle.kts`
- ❌ Ecosystem: Stabilize Kotlin Notebooks

Kotlin language features and proposals

JetBrains evolves the Kotlin language according to the Kotlin language evolution principles, guided by pragmatic design.

> Language feature proposals are listed from Kotlin 1.7.0.
>
> See the explanation of language feature statuses in the Kotlin evolution principles documentation.

All

Exploration and design	**Support immutability** • KEEP notes: immutability • YouTrack issue: KT-77734

Kotlin evolution principles

Principles of pragmatic evolution

> *Language design is cast in stone,*
>
> *but this stone is reasonably soft,*
>
> *and with some effort we can reshape it later.*
>
> *Kotlin Design Team*

Kotlin is designed to be a pragmatic tool for programmers. When it comes to language evolution, its pragmatic nature is captured by the following principles:

- Keep the language modern over time.
- Maintain a continuous feedback loop with users.
- Make updating to new versions easy and comfortable for the users.

As this is key to understanding how Kotlin is moving forward, let's expand on these principles.

Keeping the Language Modern. We recognize that systems accumulate legacy over time. What was once cutting-edge technology can become hopelessly outdated today. We have to evolve the language to keep it relevant to the needs of our users and up-to-date with their expectations. This includes not only adding new features, but also phasing out old ones that are no longer recommended for production use and have become legacy.

Comfortable Updates. Incompatible changes, such as removing things from a language, may lead to painful migration from one version to the next if carried out without proper care. We will always announce such changes well in advance, mark things as deprecated and provide automated migration tools *before the change happens*. By the time the language changes, we want most of the code in the world to be already updated and thus have no issues migrating to the new version.

Feedback Loop. Going through deprecation cycles requires significant effort, so we want to minimize the number of incompatible changes we'll be making in the future. Apart from using our best judgement, we believe that trying things out in real life is the best way to validate a design. Before casting things in stone, we want them battle-tested. This is why we use every opportunity to make early versions of our designs available in production versions of the language, but in one of the *pre-stable* statuses: Experimental, Alpha, or Beta. Such features are not stable; they can be changed at any time, and the users that opt into using them do so explicitly to indicate that they are ready to deal with the future migration issues. These users provide invaluable feedback that we gather to iterate on the design and make it rock-solid.

Incompatible changes

If, upon updating from one version to another, some code that used to work doesn't work anymore, it is an *incompatible change* in the language (sometimes referred to as a "breaking change"). There can be debates as to what "doesn't work anymore" means precisely in some cases, but it definitely includes the following:

- Code that compiled and ran fine is now rejected with an error (at compile or link time). This includes removing language constructs and adding new restrictions.
- Code that executed normally is now throwing an exception.

The less obvious cases that belong to the "gray area" include handling corner cases differently, throwing an exception of a different type than before, changing behavior observable only through reflection, modifying undocumented or undefined behavior, renaming binary artifacts, and others. Sometimes such changes are crucial and affect migration experience dramatically; sometimes they are insignificant.

Some examples of what definitely isn't an incompatible change include:

- Adding new warnings.
- Enabling new language constructs or relaxing limitations for existing ones.
- Changing private/internal APIs and other implementation details.

The principles of Keeping the Language Modern and Comfortable Updates suggest that incompatible changes are sometimes necessary, but they should be introduced carefully. Our goal is to make users aware of upcoming changes well in advance to let them migrate their code comfortably.

Ideally, every incompatible change should be announced through a compile-time warning reported in the problematic code (usually referred to as a *deprecation warning*) and accompanied by automated migration aids. So, the ideal migration workflow is as follows:

- Update to version A (where the change is announced)
  - See warnings about the upcoming change
  - Migrate the code with help from tools
- Update to version B (where the change happens)
  - See no issues at all

In practice, some changes can't be accurately detected at compile time, so no warnings can be reported, but at least the users will be notified through the release notes of version A that a change is coming in version B.

Dealing with compiler bugs

Compilers are complicated software, and despite the best efforts of their developers, they have bugs. The bugs that cause the compiler itself to fail or report spurious errors or generate obviously failing code, though annoying and often embarrassing, are easy to fix, because the fixes do not constitute incompatible changes. Other bugs may cause the compiler to generate incorrect code that does not fail: for example, by missing some errors in the source or simply generating the wrong instructions. Fixes for such bugs are technically incompatible changes (some code used to compile fine, but now it won't anymore), but we are inclined to fix them as soon as possible to prevent the bad code patterns from spreading across user code. In our opinion, this supports the principle of Comfortable Updates, because fewer users have a chance of encountering the issue. Of course, this applies only to bugs that are found soon after appearing in a released version.

Decision making

JetBrains, the original creator of Kotlin, is driving its progress with the help of the community and in collaboration with the Kotlin Foundation.

All changes to the Kotlin Programming Language are overseen by the Lead Language Designer (currently Michail Zarečenskij). The Lead Designer has the final say in all matters related to language evolution. Additionally, incompatible changes to fully stable components have to be approved by the Language Committee, designated under the Kotlin Foundation (currently comprising Jeffrey van Gogh, Werner Dietl, and Michail Zarečenskij).

The Language Committee makes final decisions on which incompatible changes will be made and what exact measures should be taken to make user updates as seamless as possible. In doing so, it relies on a set of Language committee guidelines.

Language feature delivery

As described in the Kotlin release process, language features are shipped in *language releases* (2. *x*. *0*) or their following *tooling releases* (2. *x*. *20*).

We try to keep language and tooling releases compatible with each other, so changes to the compiler are mostly optimizations and warning additions/removals. Pre-stable features may be added, removed, or changed at any time.

Language releases often add new features, promote pre-stable features to stable, and may remove or change previously deprecated ones.

EAP builds

Before releasing stable versions of language and tooling releases, we publish a number of preview builds dubbed *EAP* (for "Early Access Preview") that let us iterate faster and gather feedback from the community. EAPs of language releases usually produce binaries that will be later rejected by the stable compiler to make sure that possible bugs in the binary format survive no longer than the preview period. Final release candidates, such as RC2 or RC3, normally don't bear this limitation. For more information, see Participate in the Kotlin Early Access Preview.

Pre-stable features

According to the Feedback Loop principle described above, we iterate on our designs in the open and release versions of the language where some features have one of the *pre-stable* statuses and *are supposed to change*. Such features can be added, changed or removed at any point and without warning. We do our best to ensure that pre-stable features can't be used accidentally by an unsuspecting user. Such features usually require some sort of explicit opt-in either in the code or in the project configuration.

A Kotlin language feature can have one of the following statuses:

- **Exploration and design**. We are considering the introduction of a new feature to the language. This involves discussing how it would integrate with existing features, gathering use cases, and assessing its potential impact. We need feedback from users on the problems this feature would solve and the use cases it addresses. Whenever possible, we also try to estimate how often these use cases and problems occur. Typically, ideas are documented as YouTrack issues, where the discussion continues.
- **KEEP discussion**. We are fairly certain that the feature should be added to the language. We aim to provide motivation, use cases, design, and other important details in a document called a *Kotlin Evolution and Enhancement Process* (KEEP). We expect feedback from users to focus on discussing all the information provided in the KEEP.
- **In preview**. A feature prototype is ready, and you can enable it using a feature-specific compiler option. We seek feedback on your experience with the feature, including how easily it integrates into your codebase, how it interacts with existing code, and any IDE support issues or suggestions. The feature's design may change significantly, or it could be completely revoked based on feedback. When a feature is *in preview*, it has either Experimental or Beta stability levels.
- **Stable**. The language feature is now a first-class citizen in the Kotlin language. We guarantee its backward compatibility and that we'll provide tooling support.

- **Revoked**. We have revoked the proposal and will not implement the feature in the Kotlin language. We may revoke a feature that is *in preview* if it is not a good fit for Kotlin.

See the full list of Kotlin language proposals and their statuses.

Status of different components

Learn more about the stability status of different components in Kotlin, such as Kotlin/JVM, JS, and Native compilers, and various libraries.

Libraries

A language is nothing without its ecosystem, so we pay extra attention to enable smooth library evolution.

Ideally, a new version of a library can be used as a "drop-in replacement" for an older version. This means that upgrading a binary dependency should not break anything, even if the application is not recompiled (this is possible under dynamic linking).

On the one hand, to achieve this, the compiler has to provide certain *Application Binary Interface* (ABI) stability guarantees under the constraints of separate compilation. This is why every change in the language is examined from a binary compatibility standpoint.

On the other hand, a lot depends on the library authors being careful about which changes are safe to make. Thus, it's crucial that library authors understand how source changes affect compatibility and follow certain best practices to keep both APIs and ABIs of their libraries stable. Here are some assumptions that we make when considering language changes from the library evolution standpoint:

- Library code should always specify return types of public/protected functions and properties explicitly, thus never relying on type inference for public API. Subtle changes in type inference may cause return types to change inadvertently, leading to binary compatibility issues.
- Overloaded functions and properties provided by the same library should do essentially the same thing. Changes in type inference may result in more precise static types being known at call sites, causing changes in overload resolution.

Library authors can use the `@Deprecated` and `@RequiresOptIn` annotations to control the evolution of their API surface. Note that `@Deprecated(level=HIDDEN)` can be used to preserve binary compatibility even for declarations removed from the API.

Also, by convention, packages named "internal" are not considered public API. All API residing in packages named "experimental" is considered pre-stable and can change at any moment.

We evolve the Kotlin Standard Library (`kotlin-stdlib`) for stable platforms according to the principles stated above. Changes to the contracts for its API undergo the same procedures as changes in the language itself.

Compiler options

Command line options accepted by the compiler are also a kind of public API, and they are subject to the same considerations. Supported options (those that don't have the "-X" or "-XX" prefix) can be added only in language releases and should be properly deprecated before removing them. The "-X" and "-XX" options are experimental and can be added and removed at any time.

Compatibility tools

As legacy features get removed and bugs fixed, the source language changes, and old code that has not been properly migrated may not compile anymore. The normal deprecation cycle allows a comfortable period of time for migration, and even when it's over and the change ships in a stable version, there's still a way to compile non-migrated code.

Compatibility options

We provide compatibility options that make a new Kotlin version emulate the behavior of an older one:

- `-language-version X.Y` – compatibility mode for Kotlin language version X.Y. The compiler reports errors when your code uses language features introduced in later versions.
- `-api-version X.Y` – compatibility mode for Kotlin API version X.Y. The compiler ignores declarations that use Kotlin standard library APIs introduced in later versions, including APIs referenced by compiler-generated code.

To give you more time to migrate, on the JVM we support at least three previous language and API versions in addition to the latest stable version. This lets library authors adopt newer compiler releases while remaining compatible with consumers using older compiler versions. On other platforms, you can also configure older language and API versions, but unlike on the JVM, consumers still need to use the latest compiler version.

In most projects, set both options to the same version. A lower API version is mainly useful when you need to remain compatible with an older version of the Kotlin standard library.

Actively maintained code bases can benefit from getting bug fixes as soon as possible, without waiting for a full deprecation cycle to complete. These projects can enable the `-progressive` option to adopt these changes in tooling releases before they become the default.

You can configure these options on the command line or with the Gradle or Maven build tools.

Evolving the binary format

Unlike sources that can be fixed by hand in the worst case, binaries are a lot harder to migrate, and this makes backwards compatibility crucial in the case of binaries. Incompatible changes to binaries can make updates very uncomfortable and thus should be introduced with even more care than those in the source language syntax.

For fully stable versions of the compiler, the default binary compatibility protocol is the following:

- All binaries are backwards compatible; that means a newer compiler can read older binaries (for example, 1.3 understands 1.0 through 1.2).
- Older compilers reject binaries that rely on new features (for example, the 1.0 compiler rejects binaries that use coroutines).
- Preferably (but we can't guarantee it), the binary format is mostly forwards compatible with the next language release, but not later ones (in the cases when new features are not used, for example, 1.9 can understand most binaries from 2.0, but not 2.1).

This protocol is designed for comfortable updates as no project can be blocked from updating its dependencies even if it's using a slightly outdated compiler.

Note that not all target platforms have reached this level of stability, but Kotlin/JVM has.

Kotlin klib binaries

Kotlin klib binaries have reached the Stable level in Kotlin 1.9.20. However, there are some compatibility details you need to keep in mind:

- klib binaries are backwards compatible starting with Kotlin 1.9.20. For example, the 2.0.x compiler can read binaries produced by the 1.9.2x compiler.
- Forward compatibility is *not* guaranteed. For example, the 2.0.x compiler is *not* guaranteed to read binaries produced by the 2.1.x compiler.

The Kotlin cinterop klib binaries are still in Beta. Currently, we cannot give specific compatibility guarantees between different Kotlin versions for cinterop klib binaries.

Stability of Kotlin components

The Kotlin language and toolset are divided into many components such as the compilers for the JVM, JS and Native targets, the Standard Library, various accompanying tools, and so on. Many of these components were officially released as **Stable**, which means that they were evolved in a backward-compatible way following the principles of *Comfortable Updates* and *Keeping the Language Modern*.

Following the *Feedback Loop* principle, we release many things early for the community to try out, so a number of components are not yet released as **Stable**. Some of them are at a very early stage, some are more mature. We mark them as **Experimental**, **Alpha** or **Beta** depending on how quickly each component evolves and the level of risk users take on when adopting it.

Stability levels explained

Here's a quick guide to these stability levels and their meaning:

Experimental means "try it only in toy projects":

- We're just testing an idea and its feasibility. We want some users to try it out and share their feedback. The scope is minimal, and the feature may change or disappear at any time. We don't guarantee stability or compatibility.

Alpha means "we are testing whether this should become production-ready":

- We intend to turn this into a product and are validating its user value and market fit to shape its final form. The feature set is still incomplete, and breaking changes are expected. If the hypothesis doesn't hold, we may significantly change or discontinue the feature.

Beta means "you can use it, we'll do our best to minimize migration issues for you":

- It's almost done, user feedback is especially important now.
- Still, it's not 100% finished, so changes are possible (including ones based on your own feedback).
- Watch for deprecation warnings in advance for the best update experience.

We collectively refer to *Experimental*, *Alpha* and *Beta* as **pre-stable** levels.

Stable means "use it even in most conservative scenarios":

- It's done. We will be evolving it according to our strict backward compatibility rules.

Please note that stability levels do not say anything about how soon a component will be released as Stable. Similarly, they do not indicate how much a component will be changed before release. They only say how fast a component is changing and how much risk of update issues users are running.

GitHub badges for Kotlin components

The Kotlin GitHub organization hosts different Kotlin-related projects. Some of them we develop full-time, while others are side projects.

Each Kotlin project has two GitHub badges describing its stability and support status:

- **Stability** status. This shows how quickly each project is evolving and how much risk the users are taking when adopting it. The stability status completely coincides with the stability level of the Kotlin language features and its components:
  - 

 stands for **Experimental**
  - 

 stands for **Alpha**
  - 

 stands for **Beta**
  - 

 stands for **Stable**
- **Support** status. This shows our commitment to maintaining a project and helping users to solve their problems. The level of support is unified for all JetBrains products.
  See the JetBrains Open Source document for details.

Stability of subcomponents

A stable component may have an experimental subcomponent, for example:

- a stable compiler may have an experimental feature;
- a stable API may include experimental classes or functions;
- a stable command-line tool may have experimental options.

We make sure to document precisely which subcomponents are not **Stable**. We also do our best to warn users where possible and ask to opt them in explicitly to avoid the accidental use of features that have not been released as stable.

Current stability of Kotlin components

By default, all new components have Experimental status.

Kotlin compiler

Component	Status	Status since version	Comments
Kotlin/JVM	Stable	1.0.0	

Component	Status	Status since version	Comments
Kotlin/Native	Stable	1.9.0	
Kotlin/JS	Stable	1.3.0	
Kotlin/Wasm	Beta	2.2.20	
Analysis API	Stable		

Core compiler plugins

Component	Status	Status since version	Comments
All-open	Stable	1.3.0	
No-arg	Stable	1.3.0	
SAM-with-receiver	Stable	1.3.0	
kapt	Stable	1.3.0	
Lombok	Alpha	2.3.20	
Power-assert	Experimental	2.0.0	

Kotlin libraries

Component	Status	Status since version	Comments
kotlin-stdlib (JVM)	Stable	1.0.0	
kotlinx-coroutines	Stable	1.3.0	
kotlinx-serialization	Stable	1.0.0	
kotlin-metadata-jvm	Stable	2.0.0	
kotlin-reflect (JVM)	Beta	1.0.0	
kotlinx-datetime	Alpha	0.2.0	

Component	Status	Status since version	Comments
kotlinx-io	Alpha	0.2.0	
kotlinx-collections-immutable	Alpha	0.3.5	

Kotlin Multiplatform

Component	Status	Status since version	Comments
Kotlin Multiplatform	Stable	1.9.20	
Kotlin Multiplatform plugin for Android Studio	Beta	0.8.0	Versioned separately from the language

Kotlin/Native

Component	Status	Status since version	Comments
Kotlin/Native Runtime	Stable	1.9.20	
Kotlin/Native interop with C and Objective-C	Beta	1.3.0	Stability of C and Objective-C library import
klib binaries	Stable	1.9.20	Not including cinterop klibs, see below
cinterop klib binaries	Beta	1.3.0	Stability of C and Objective-C library import
CocoaPods integration	Stable	1.9.20	

For more information about the level of support for different targets, see Kotlin/Native supported targets and hosts.

Build tools

Component	Status	Status since version	Comments
Kotlin Gradle plugin	Stable	1.1.1	The Kotlin Multiplatform Gradle plugin is stable from Kotlin 1.9.20.
Kotlin Maven plugin	Stable	1.0.0	

Build tools API (BTA)

Component	Status	Status since version	Comments
BTA for JVM	Beta	2.4.20	
BTA for JS	Alpha	2.4.20	
BTA for Wasm	Alpha	2.4.20	

The Build tools API currently doesn't support Kotlin/Native.

Language tools

Component	Status	Status since version	Comments
Scripting syntax and semantics	Alpha	1.2.0	
Scripting embedding and extension API	Beta	1.5.0	
Scripting IDE support	Beta		Available since IntelliJ IDEA 2023.1 and later
CLI scripting	Alpha	1.2.0	

Language features and design proposals

For language features and new design proposals, see Kotlin language features and proposals.

Kotlin release process

This page explains the Kotlin release cycle and the different types of releases we ship. It also includes details about past and upcoming Kotlin releases, along with instructions on how to update to a specific release.

Since Kotlin 2.0.0, we ship the following types of releases:

- *Language releases* (2. *x*. *0*) that bring major changes in the language and include tooling updates. Released once in 6 months.
- *Tooling releases* (2. *x*. *20*) that are shipped between language releases and include updates in the tooling, performance improvements, and bug fixes. Released in 3 months after corresponding *language release*.
- *Bug fix releases* (2. *x*. *yz*) that include bug fixes for *tooling releases*. There is no exact release schedule for these releases.

For example, for the language release 2.2.0, there was only one tooling release 2.2.20 and one bug fix release 2.2.21.

For each language and tooling release, we also ship several preview (*EAP*) versions for you to try new features before they are released. For more information, see Participate in the Kotlin Early Access Preview.

If you want to be notified about new Kotlin releases, subscribe to the Kotlin newsletter, follow Kotlin on X, or enable the **Watch | Custom | Releases** option on the Kotlin GitHub repository.

Upcoming Kotlin releases

Here is the approximate schedule for upcoming stable Kotlin releases:

- **2.5.0**: Planned for December 2026
- **2.5.20**: Planned for March 2027

Update to a new Kotlin version

To upgrade your project to a new release, update the Kotlin version in your build system.

Gradle

To update to Kotlin 2.4.20, change the version of the Kotlin Gradle plugin in your `build.gradle(.kts)` file:

Kotlin

```
plugins {
    // Replace `<...>` with the plugin name appropriate for your target environment
    kotlin("<...>") version "2.4.20"
    // For example, if your target environment is JVM:
    // kotlin("jvm") version "2.4.20"
    // If your target is Kotlin Multiplatform:
    // kotlin("multiplatform") version "2.4.20"
}
```

Groovy

```
plugins {
    // Replace `<...>` with the plugin name appropriate for your target environment
    id 'org.jetbrains.kotlin.<...>' version '2.4.20'
    // For example, if your target environment is JVM:
    // id 'org.jetbrains.kotlin.jvm' version '2.4.20'
    // If your target is Kotlin Multiplatform:
    // id 'org.jetbrains.kotlin.multiplatform' version '2.4.20'
}
```

If you have projects created with earlier Kotlin versions, check if you also need to update the version of any kotlinx libraries.

If you are migrating to a new language release, the Kotlin plugin's migration tools will help you with the process.

To learn more about how to work with Gradle in your project, see Configure a Gradle project.

Maven

To update to Kotlin 2.4.20, change the version in your `pom.xml` file:

```
<properties>
    <kotlin.version>2.4.20</kotlin.version>
</properties>
```

Alternatively, you can change the version of the `kotlin-maven-plugin` in your `pom.xml` file:

```
<plugins>
    <plugin>
        <groupId>org.jetbrains.kotlin</groupId>
        <artifactId>kotlin-maven-plugin</artifactId>
        <version>2.4.20</version>
    </plugin>
</plugins>
```

If you have projects created with earlier Kotlin versions, check if you also need to update the version of any kotlinx libraries.

To learn more about how to work with Maven in your project, see Maven.

IDE support

Kotlin has full out-of-the-box support in IntelliJ IDEA and Android Studio.

Standard library security support

Starting with Kotlin 2.4.0, the Kotlin standard library for the JVM has an 18–month support window for each release line. Language releases (2. *x*. *0*) and the following tooling releases (2. *x*. *20*) belong to the same release line (2. *x*).

If we discover a security vulnerability that affects the Kotlin standard library for the JVM, we ship the following simultaneously:

- A bug fix release based on the latest Kotlin release in the release line that includes the security fix.
- Bug fix releases for every release line within its active support window.

For example, if we discover a security vulnerability and the latest Kotlin release is Kotlin 2.4.20, we release a bug fix version for Kotlin 2.4.20 only. We don't release a bug fix version for Kotlin 2.4.0.

The following table lists all Kotlin releases and their support windows:

Kotlin release line	Release date	End of support	Latest bug fix release
2.4	June 3, 2026	December 3, 2027	2.4.10

We always want to hear about any security issues you find. To report problems that you discover in Kotlin, post a message directly to our issue tracker or send us an email.

Release history

The following table lists details of previous Kotlin releases:

You can also try Early Access Preview (EAP) versions of Kotlin.

Build info	Build highlights
2.4.20 Released: September 7, 2026 Release on GitHub	A tooling release with new experimental and stable features, performance improvements, bug fixes, and tooling updates. For more details, please refer to the changelog.
2.4.10 Released: July 14, 2026 Release on GitHub	A bug fix release for Kotlin 2.4.0. For more details, refer to the changelog.
2.4.0 Released: June 3, 2026 Release on GitHub	A language release including both new and stable language features, tooling updates, performance improvements for different platforms, and important fixes. Learn more about Kotlin 2.4.0 in What's new in Kotlin 2.4.0.
2.3.21 Released: April 23, 2026 Release on GitHub	A bug fix release for Kotlin 2.3.20. For more details, please refer to the changelog.
2.3.20 Released: March 16, 2026 Release on GitHub	A tooling release with performance improvements, bug fixes, and tooling updates. For more details, please refer to the changelog.
2.3.10 Released: February 5, 2026	A bug fix release for Kotlin 2.3.0 that includes performance improvements and an important fix for a rare race condition with `kotlinx.serialization`. For more details, please refer to the changelog.

Build info	Build highlights
Release on GitHub	
2.3.0 Released: December 16, 2025 Release on GitHub	A language release including both new and stable language features, tooling updates, performance improvements for different platforms, and important fixes. Learn more about Kotlin 2.3.0 in What's new in Kotlin 2.3.0.
2.2.21 Released: October 23, 2025 Release on GitHub	A bug fix release containing support for Xcode 26, along with other improvements and bug fixes. For more details, please refer to the changelog.
2.2.20 Released: September 10, 2025 Release on GitHub	A tooling release for Kotlin 2.2.0 that contains important changes for web development and other improvements. Learn more about Kotlin 2.2.20 in What's new in Kotlin 2.2.20.
2.2.10 Released: August 14, 2025 Release on GitHub	A bug fix release for Kotlin 2.2.0. For more details, please refer to the changelog.
2.2.0 Released: June 23, 2025 Release on GitHub	A language release including both new and stable language features, tooling updates, performance improvements for different platforms, and important fixes. Learn more about Kotlin 2.2.0 in What's new in Kotlin 2.2.0.
2.1.21 Released: May 13, 2025 Release on GitHub	A bug fix release for Kotlin 2.1.20. For more details, please refer to the changelog.
2.1.20 Released: March 20, 2025 Release on GitHub	A tooling release for Kotlin 2.1.0 containing new experimental features, performance improvements, and bug fixes. Learn more about Kotlin 2.1.20 in What's new in Kotlin 2.1.20.

Build info	Build highlights
2.1.10 Released: January 27, 2025 Release on GitHub	A bug fix release for Kotlin 2.1.0 For more details, please refer to the changelog.
2.1.0 Released: November 27, 2024 Release on GitHub	A language release introducing new language features. Learn more about Kotlin 2.1.0 in What's new in Kotlin 2.1.0.
2.0.21 Released: October 10, 2024 Release on GitHub	A bug fix release for Kotlin 2.0.20 For more details, please refer to the changelog.
2.0.20 Released: August 22, 2024 Release on GitHub	A tooling release for Kotlin 2.0.0 containing performance improvements and bug fixes. Features also include concurrent marking in Kotlin/Native's garbage collector, UUID support in Kotlin common standard library, Compose compiler updates, and support up to Gradle 8.8. Learn more about Kotlin 2.0.20 in What's new in Kotlin 2.0.20.
2.0.10 Released: August 6, 2024 Release on GitHub	A bug fix release for Kotlin 2.0.0. Learn more about Kotlin 2.0.0 in What's new in Kotlin 2.0.0.
2.0.0 Released: May 21, 2024 Release on GitHub	A language release with the Stable Kotlin K2 compiler. Learn more about Kotlin 2.0.0 in What's new in Kotlin 2.0.0.
1.9.25 Released: July 19, 2024 Release on GitHub	A bug fix release for Kotlin 1.9.20, 1.9.21, 1.9.22, 1.9.23, and 1.9.24. Learn more about Kotlin 1.9.20 in What's new in Kotlin 1.9.20.
1.9.24	A bug fix release for Kotlin 1.9.20, 1.9.21, 1.9.22, and 1.9.23.

Build info	Build highlights
Released: May 7, 2024 Release on GitHub	Learn more about Kotlin 1.9.20 in What's new in Kotlin 1.9.20.
1.9.23 Released: March 7, 2024 Release on GitHub	A bug fix release for Kotlin 1.9.20, 1.9.21, and 1.9.22. Learn more about Kotlin 1.9.20 in What's new in Kotlin 1.9.20.
1.9.22 Released: December 21, 2023 Release on GitHub	A bug fix release for Kotlin 1.9.20 and 1.9.21. Learn more about Kotlin 1.9.20 in What's new in Kotlin 1.9.20.
1.9.21 Released: November 23, 2023 Release on GitHub	A bug fix release for Kotlin 1.9.20. Learn more about Kotlin 1.9.20 in What's new in Kotlin 1.9.20.
1.9.20 Released: November 1, 2023 Release on GitHub	A feature release with Kotlin K2 compiler in Beta and Stable Kotlin Multiplatform. Learn more in: • What's new in Kotlin 1.9.20
1.9.10 Released: August 23, 2023 Release on GitHub	A bug fix release for Kotlin 1.9.0. Learn more about Kotlin 1.9.0 in What's new in Kotlin 1.9.0. For Android Studio Giraffe and Hedgehog, the Kotlin plugin 1.9.10 will be delivered with upcoming Android Studios updates.
1.9.0 Released: July 6, 2023 Release on GitHub	A feature release with Kotlin K2 compiler updates, new enum class values function, new operator for open-ended ranges, preview of Gradle configuration cache in Kotlin Multiplatform, changes to Android target support in Kotlin Multiplatform, preview of custom memory allocator in Kotlin/Native. Learn more in: • What's new in Kotlin 1.9.0 •

What's new in Kotlin 2.3.20

Released: March 16, 2026

The Kotlin 2.3.20 release is out! Here are the main highlights:

- **Gradle**: Compatibility with Gradle 9.3.0 and Kotlin/JVM compilation uses BTA by default
- **Maven**: Simplified setup for Kotlin projects
- **Kotlin compiler plugins**: Lombok is in Alpha and improved JPA support in the `kotlin.plugin.jpa` plugin
- **Language**: Support for name-based destructuring declarations
- **Standard library**: New API for creating immutable copies of `Map.Entry`
- **Kotlin/Native**: New interoperability mode for C and Objective-C libraries

For information about the Kotlin release cycle, see Kotlin release process.

Update to Kotlin 2.3.20

The latest version of Kotlin is included in the latest versions of IntelliJ IDEA and Android Studio.

To update to the new Kotlin version, make sure your IDE is updated to the latest version and change the Kotlin version to 2.3.20 in your build scripts.

Stable

New features

The following feature is Stable in this release:

Simplified setup for Kotlin projects

Kotlin 2.3.20 makes it easier to set up Kotlin in Maven projects. Now Kotlin supports the automatic configuration of source roots and Kotlin's standard library.

With the new configuration, when you create a new Kotlin project with the Maven build system or introduce Kotlin to your existing Java Maven project, you don't need to manually specify source root paths or add the `kotlin-stdlib` dependency in your POM build file.

How to enable

In your `pom.xml` file, add `<extensions>true</extensions>` to the `<build><plugins>` section of the Kotlin Maven plugin:

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>2.4.20</version>
            <extensions>true</extensions> <!-- Add this extension  -->
        </plugin>
    </plugins>
</build>
```

The new features of the `<extensions>` option here are:

- Registering `src/main/kotlin` and `src/test/kotlin` directories as source roots in case they already exist but are not specified in the plugin configuration.
- Adding the `kotlin-stdlib` dependency in case it's not explicitly defined already.

You can also opt out of the automatic addition of Kotlin's standard library. For that, add the following to the `<properties>` section:

```
<project>
    <properties>
        <!-- Disable smart defaults via property -->
        <kotlin.smart.defaults.enabled>false</kotlin.smart.defaults.enabled>
    </properties>
</project>
```

Note that this property disables not only automatic addition of the standard library, but also the registration of source root paths. Other `<extensions>` features are not affected.

For more information on configuring Kotlin Maven projects, see Configure a Maven project.

New features

The following pre-stable features are available in this release. This includes features with Beta, Alpha, and Experimental status:

- Compiler: Lombok is now in Alpha
- Language: Name-based destructuring
- Standard library: New API for creating immutable copies of `Map.Entry`
- Kotlin/Native: New interoperability mode for C or Objective-C libraries

Lombok is now in Alpha

Kotlin 1.5.20 introduced the experimental Lombok compiler plugin, which lets you generate and use Java's Lombok declarations in modules that mix Kotlin and Java code.

In 2.3.20, the Lombok compiler plugin has been promoted to Alpha because we plan to make this functionality production-ready, but it's still under development.

Experimental

Name-based destructuring

Kotlin 2.3.20 introduces *name-based destructuring declarations*, which match variables to property names instead of relying on position-based `componentN()` functions.

Previously, destructuring declarations used position-based destructuring:

```
data class User(val username: String, val email: String)

fun main() {
    val user = User("alice", "alice@example.com")

    val (email, username) = user

    println(email)
    // alice

    println(username)
    // alice@example.com
}
```

In this example, because destructuring relies on the order of `componentN()` functions, `email` receives the value of `username`, and `username` receives the value of `email`.

Starting with Kotlin 2.3.20, you can use name-based destructuring where each variable refers to a property by name:

```
fun main() {
    val user = User("alice", "alice@example.com")

    // Uses name-based destructuring with explicit form
    (val mail = email, val name = username) = user

    println(name)
    // alice

    println(mail)
    // alice@example.com
}
```

Name-based destructuring is Experimental. You can control how the compiler interprets destructuring declarations with the `-Xname-based-destructuring` compiler option.

It has the following modes:

- `only-syntax` enables the explicit form of name-based destructuring without changing the behavior of existing destructuring declarations.
- `name-mismatch` reports warnings when position-based destructuring in data classes uses variable names that don't match the property names.

- `complete` enables short-form name-based destructuring with parentheses and continues supporting position-based destructuring with square bracket syntax.

If you use `complete` mode, the short-form destructuring syntax with parentheses matches variables to property names instead of relying on position:

```
val (email, username) = user
```

How to enable

To use named-based destructuring in your project, add the compiler option to your build configuration file:

Gradle

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xname-based-destructuring=only-syntax")
    }
}
```

Maven

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-Xname-based-destructuring=only-syntax</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

Opting in to name-based destructuring also introduces a new syntax for position-based destructuring using square brackets:

```
// Uses explicit position-based destructuring
val [username, email] = user
```

We plan to gradually move toward destructuring declarations using name-based matching by default, while preserving position-based destructuring with the new square bracket syntax.

For more information, see the feature's KEEP.

We would appreciate your feedback in YouTrack.

Experimental

New API for creating immutable copies of `Map.Entry`

Kotlin 2.3.20 introduces the `Map.Entry.copy()` extension function for creating an immutable copy of a `Map.Entry`. This function allows you to reuse entries obtained from `Map.entries` after modifying the map by copying them first.

`Map.Entry.copy()` is Experimental. To opt in, use the `@OptIn(ExperimentalStdlibApi::class)` annotation or the compiler option:

```
-opt-in=kotlin.ExperimentalStdlibApi
```

Here's an example of using `Map.Entry.copy()` to remove entries from a mutable map:

```
@OptIn(ExperimentalStdlibApi::class)
fun main() {
    val map = mutableMapOf(1 to 1, 2 to 2, 3 to 3, 4 to 4)

    val toRemove = map.entries
        .filter { it.key % 2 == 0 }
        .map { it.copy() }

    map.entries.removeAll(toRemove)

    println("map = $map")
    // map = {1=1, 3=3}
}
```

Experimental

New interoperability mode for C or Objective-C libraries

If you use C or Objective-C libraries in your Kotlin Multiplatform (KMP) libraries or applications, we invite you to test the new interoperability mode and share the results.

In general, Kotlin/Native enables importing C and Objective-C libraries into Kotlin. However, for KMP libraries, this functionality is currently affected by the KMP compatibility issues with older compiler versions.

In other words, if you publish a KMP library compiled with one Kotlin version, importing C or Objective-C libraries might make it impossible to use that Kotlin library in projects with an earlier Kotlin version.

To address this and other issues, the Kotlin team has been revising the interoperability mechanism used under the hood. Starting with Kotlin 2.3.20, you can try the new mode through a compiler option.

How to enable

1. In your Gradle build file, check whether you have a `cinterops {}` block or a `pod()` dependency. If these are present, your project uses C or Objective-C libraries.
2. Ensure your project uses `2.3.20` or a later version.
3. In the same build file, add the `-Xccall-mode` compiler option to the cinterop tool invocation:

```
kotlin {
    targets.withType<org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget>().configureEach {
        compilations.configureEach {
            cinterops.configureEach {
                extraOpts += listOf("-Xccall-mode", "direct")
            }
        }
    }
}
```

4. Build and test your project as usual by running unit tests, the app, and so on. You can also use the `--continue` option to allow Gradle to continue executing tasks even after failures, helping to find more problems at once.

Do **not** publish libraries compiled with the new interoperability mode yet, as it's still Experimental.

Report your results

The new interoperability mode is supposed to be a drop-in replacement in most cases. We're planning to eventually enable it by default. But to achieve that, we need to ensure it works as well as possible and test it on a wide range of projects, because:

- Some C and Objective-C declarations aren't yet supported in the new mode (mostly because of compatibility issues). We'd like to better understand the real-world impact of this and prioritize future steps accordingly.
- There may be bugs or things we haven't considered. Testing languages with numerous interacting features is challenging, and testing the interaction between languages (each with a unique set of features) is even more so.

Help us examine real-world projects and identify challenging cases. Whether you encounter any issues or not, share your results in the comments to in YouTrack.

Language

Kotlin 2.3.20 adds name-based destructuring declarations that match variables to property names instead of relying on position. It also introduces changes to overload resolution for declarations with context parameters.

Changes to overload resolution for context parameters

Kotlin 2.3.20 introduces changes to overload resolution for declarations with context parameters.

Previously, overload resolution treated declarations with context parameters as more specific than those without them.

Starting with Kotlin 2.3.20, this rule no longer applies, making overload selection more uniform. As a result, calls that previously resolved now become ambiguous, resulting in a compilation error when overloads differ only by context parameters. In such cases, the compiler warns about potential ambiguity.

Here's an example:

```
class Logger {
    fun info(msg: String) = println("INFO: $msg")
}

fun saveUser(id: Int) {
    println("Saving user $id (no logger)")
}

// Reports a warning: Contextual declaration is shadowed
context(logger: Logger)
fun saveUser(id: Int) {
    logger.info("Saving user $id")
}

fun main() {
    val logger = Logger()

    context(logger) {
        // Reports an ambiguity error in 2.3.20
        saveUser(1)
    }
}
```

Additionally, Kotlin 2.3.20 reduces the number of `kotlin.context` overloads from 22 to 6 to reduce excessive overload candidates during resolution and code completion.

Experimental

Name-based destructuring

Kotlin 2.3.20 introduces *name-based destructuring declarations*, which match variables to property names instead of relying on position-based `componentN()` functions.

Previously, destructuring declarations used position-based destructuring:

```
data class User(val username: String, val email: String)

fun main() {
    val user = User("alice", "alice@example.com")

    val (email, username) = user

    println(email)
    // alice

    println(username)
    // alice@example.com
}
```

In this example, because destructuring relies on the order of `componentN()` functions, `email` receives the value of `username`, and `username` receives the value of `email`.

Starting with Kotlin 2.3.20, you can use name-based destructuring where each variable refers to a property by name:

```
fun main() {
    val user = User("alice", "alice@example.com")

    // Uses name-based destructuring with explicit form
    (val mail = email, val name = username) = user

    println(name)
    // alice

    println(mail)
    // alice@example.com
}
```

Name-based destructuring is Experimental. You can control how the compiler interprets destructuring declarations with the `-Xname-based-destructuring` compiler option.

It has the following modes:

- `only-syntax` enables the explicit form of name-based destructuring without changing the behavior of existing destructuring declarations.
- `name-mismatch` reports warnings when position-based destructuring in data classes uses variable names that don't match the property names.
- `complete` enables short-form name-based destructuring with parentheses and continues supporting position-based destructuring with square bracket syntax.

If you use `complete` mode, the short-form destructuring syntax with parentheses matches variables to property names instead of relying on position:

```
val (email, username) = user
```

How to enable

To use named-based destructuring in your project, add the compiler option to your build configuration file:

Gradle

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xname-based-destructuring=only-syntax")
    }
}
```

Maven

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-Xname-based-destructuring=only-syntax</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

Opting in to name-based destructuring also introduces a new syntax for position-based destructuring using square brackets:

```
// Uses explicit position-based destructuring
val [username, email] = user
```

We plan to gradually move toward destructuring declarations using name-based matching by default, while preserving position-based destructuring with the new square bracket syntax.

For more information, see the feature's KEEP.

We would appreciate your feedback in YouTrack.

Standard library

Kotlin 2.3.20 includes a new experimental feature for the standard library.

Experimental

New API for creating immutable copies of `Map.Entry`

Kotlin 2.3.20 introduces the `Map.Entry.copy()` extension function for creating an immutable copy of a `Map.Entry`. This function allows you to reuse entries obtained from `Map.entries` after modifying the map by copying them first.

`Map.Entry.copy()` is Experimental. To opt in, use the `@OptIn(ExperimentalStdlibApi::class)` annotation or the compiler option:

```
-opt-in=kotlin.ExperimentalStdlibApi
```

Here's an example of using `Map.Entry.copy()` to remove entries from a mutable map:

```kotlin
@OptIn(ExperimentalStdlibApi::class)
fun main() {
    val map = mutableMapOf(1 to 1, 2 to 2, 3 to 3, 4 to 4)

    val toRemove = map.entries
        .filter { it.key % 2 == 0 }
        .map { it.copy() }

    map.entries.removeAll(toRemove)

    println("map = $map")
    // map = {1=1, 3=3}
}
```

Kotlin compiler plugins

Kotlin 2.3.20 brings important updates to the Lombok and `kotlin.plugin.jpa` compiler plugins.

Improved JPA support in the `kotlin.plugin.jpa` plugin

The `kotlin.plugin.jpa` plugin now automatically applies the `all-open` compiler plugin with the newly added built-in JPA preset, in addition to applying the existing `no-arg` compiler plugin.

Previously, using `kotlin("plugin.jpa")` enabled only the `no-arg` plugin with JPA presets.

In this release, we improved the `kotlin.plugin.jpa` preset so the `all-open` plugin is configured automatically. This ensures that lazy associations work as expected instead of causing eager loading and triggering extra queries.

Starting with Kotlin 2.3.20:

- The `all-open` compiler plugin provides a JPA preset.
- The Gradle `org.jetbrains.kotlin.plugin.jpa` plugin automatically applies the `org.jetbrains.kotlin.plugin.all-open` plugin with the JPA preset enabled.
- The Maven JPA setup enables `all-open` with the JPA preset by default. (Support in IntelliJ IDEA is available from 2026.1.)
- The Maven dependency `org.jetbrains.kotlin:kotlin-maven-noarg` now implicitly includes `org.jetbrains.kotlin:kotlin-maven-allopen`, so you no longer need to add it explicitly in the `<plugin> <dependencies>` block.

As a result, JPA entities annotated with the following annotations are automatically treated as `open` and receive no-argument constructors without additional configuration:

- `javax.persistence.Entity`
- `javax.persistence.Embeddable`
- `javax.persistence.MappedSuperclass`
- `jakarta.persistence.Entity`
- `jakarta.persistence.Embeddable`
- `jakarta.persistence.MappedSuperclass`

This change simplifies build configuration and improves the out-of-the-box experience when using Kotlin with JPA frameworks.

The upcoming release of IntelliJ IDEA 2026.1 automatically configures the `kotlin.plugin.jpa` plugin when setting up Kotlin in a project. The IDE offers a quick-fix to add the plugin and remove any redundant no-arg constructor declarations.

Lombok is now in Alpha

Kotlin 1.5.20 introduced the experimental Lombok compiler plugin, which lets you generate and use Java's Lombok declarations in modules that mix Kotlin and Java code.

In 2.3.20, the Lombok compiler plugin has been promoted to Alpha because we plan to make this functionality production-ready, but it's still under development.

Kotlin/JVM

Kotlin 2.3.20 introduces several improvements to Java interoperability. The compiler now recognizes the Vert.x `@Nullable` annotation for nullability checks. This release also adds support for the Java `@Unmodifiable` and `@UnmodifiableView` annotations to treat annotated collections as read-only in Kotlin.

Support for Vert.x `@Nullable` annotation

Kotlin 2.3.20 adds support for the `io.vertx.codegen.annotations.Nullable` annotation. The compiler now recognizes this annotation and reports nullability mismatches as warnings by default.

To enforce strict nullability checks and upgrade these warnings to errors, add the following compiler option to your build file:

Gradle

```
// build.gradle(.kts)
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xnullability-annotations=@io.vertx.codegen.annotations:strict")
    }
}
```

Maven

```
<!-- pom.xml -->
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-Xnullability-annotations=@io.vertx.codegen.annotations:strict</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

Support for Java unmodifiable collection annotations

Kotlin 2.3.20 adds support for the `org.jetbrains.annotations.Unmodifiable` and `org.jetbrains.annotations.UnmodifiableView` Java annotations.

Starting from Kotlin 2.3.20, collections returned from Java declarations marked with these annotations are treated as read-only in Kotlin. Assigning them to a mutable collection type results in a type mismatch warning. This warning is scheduled to become an error in Kotlin 2.5.0.

Here's an example:

```java
// Java
public class Java {
    public static @UnmodifiableView List<Object> unmodifiableView() {
        return List.of();
    }

    public static @Unmodifiable List<Object> unmodifiable() {
        return List.of();
    }
}
```

```kotlin
// Kotlin

fun main() {
    // Reports a warning: Java type mismatch
    val mutableView: MutableList<Any> = Java.unmodifiableView()
    val mutableCopy: MutableList<Any> = Java.unmodifiable()
}
```

Kotlin/Native

Kotlin 2.3.20 introduces a new experimental interoperability mode for C and Objective-C libraries, a cross-compilation checker, and a new DSL for disabling the compilation cache in Kotlin/Native projects.

Cross-compilation checker

Kotlin 2.3.20 introduces a way to determine if cross-compilation is supported for the given target. This can be useful for third-party plugins that follow the status of compilation tasks.

Generally, Kotlin/Native allows cross-compilation, meaning that any supported host can produce `.klib` artifacts for supported targets. However, artifact production for Apple targets is still limited if your project uses cinterop dependencies.

The new `crossCompilationSupported` API now checks whether cross-compilation is supported: the target should be enabled by the host manager, and none of the target's compilations should involve cinterop dependencies. The checker is enabled by default.

For more information on supported targets and hosts, see the Kotlin/Native documentation.

New DSL for disabling compilation cache

Kotlin 2.3.20 comes with a new DSL for disabling the compilation cache in Kotlin/Native projects. It's intended to make the decision of disabling the cache more considered and explicit.

Since disabling the cache makes Kotlin/Native builds significantly slower, it should be used only temporarily and in exceptional cases. That's why disabling the cache is now tied to a specific Kotlin version and must include a reason, which acts as documentation.

If you do need to disable the compilation cache in your project, update the `binaries {}` block in your Gradle build file as follows:

```
kotlin {
    listOf(
        iosX64(),
        iosArm64(),
        iosSimulatorArm64()
    ).forEach {
        // Specify your binary kind
        it.binaries.framework {
            baseName = "CacheKind"
            isStatic = true

            // Disable cache with the new DSL
            disableNativeCache(
                 version = DisableCacheInKotlinVersion.2_3_0,
                 reason = "Cache bug",
                 issue = URI("https://youtrack.com/YY-1111")
            )
        }
    }
}
```

- `version` – the Kotlin version for which the compilation cache is disabled.
- `reason` (mandatory) – the reason why the compilation cache is disabled.
- `issue` (optional) – a URL to the corresponding issue in your bug tracker.

The new DSL replaces the deprecated `kotlin.native.cacheKind` Gradle property. You can safely remove it from your `gradle.properties` file.

For more tips on improving compilation times, see the Kotlin/Native documentation.

Experimental

New interoperability mode for C or Objective-C libraries

If you use C or Objective-C libraries in your Kotlin Multiplatform (KMP) libraries or applications, we invite you to test the new interoperability mode and share the results.

In general, Kotlin/Native enables importing C and Objective-C libraries into Kotlin. However, for KMP libraries, this functionality is currently affected by the KMP compatibility issues with older compiler versions.

In other words, if you publish a KMP library compiled with one Kotlin version, importing C or Objective-C libraries might make it impossible to use that Kotlin library in projects with an earlier Kotlin version.

To address this and other issues, the Kotlin team has been revising the interoperability mechanism used under the hood. Starting with Kotlin 2.3.20, you can try the new mode through a compiler option.

How to enable

1. In your Gradle build file, check whether you have a `cinterops {}` block or a `pod()` dependency. If these are present, your project uses C or Objective-C libraries.
2. Ensure your project uses `2.3.20` or a later version.

3. In the same build file, add the `-Xccall-mode` compiler option to the cinterop tool invocation:

```
kotlin {
    targets.withType<org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget>().configureEach {
        compilations.configureEach {
            cinterops.configureEach {
                extraOpts += listOf("-Xccall-mode", "direct")
            }
        }
    }
}
```

4. Build and test your project as usual by running unit tests, the app, and so on. You can also use the `--continue` option to allow Gradle to continue executing tasks even after failures, helping to find more problems at once.

Do **not** publish libraries compiled with the new interoperability mode yet, as it's still Experimental.

Report your results

The new interoperability mode is supposed to be a drop-in replacement in most cases. We're planning to eventually enable it by default. But to achieve that, we need to ensure it works as well as possible and test it on a wide range of projects, because:

- Some C and Objective-C declarations aren't yet supported in the new mode (mostly because of compatibility issues). We'd like to better understand the real-world impact of this and prioritize future steps accordingly.
- There may be bugs or things we haven't considered. Testing languages with numerous interacting features is challenging, and testing the interaction between languages (each with a unique set of features) is even more so.

Help us examine real-world projects and identify challenging cases. Whether you encounter any issues or not, share your results in the comments to in YouTrack.

Kotlin/Wasm

Kotlin 2.3.20 improves the performance of string operations, compilation time, and memory usage. It also adds support for the experimental `@nativeInvoke` annotation, which lets you call Kotlin objects or classes like JavaScript functions.

Improved string performance

Kotlin/Wasm now uses JS String builtins for operations on `kotlin.String` values. This allows Kotlin/Wasm to benefit from JavaScript engine string optimizations in browsers and Wasm runtimes supporting the proposal. The optimization applies to operations such as concatenation, interpolation, `StringBuilder.append()`, and number-to-string conversion.

It results in:

- Up to 4.6 times faster string interpolation in targeted benchmarks.
- Approximately 5% smaller Wasm binaries in the KotlinConf application build.
- Around 1% median improvement across all Wasm benchmarks.
- At least 20% faster `StringBuilder.append()` and concatenation of `kotlin.String` instances in append-heavy workloads.

Improved compilation time and memory optimizations

Kotlin 2.3.20 adds compiler optimizations that significantly reduce memory consumption during compilation, especially in large projects. These optimizations also improve incremental build performance.

In our testing, we observed a 65% improvement in clean build times and a 21% improvement in incremental build times.

Experimental

Support for `@nativeInvoke` annotation

Kotlin 2.3.20 introduces support for the `@nativeInvoke` annotation for the `wasmJs` target. This annotation allows you to treat a Kotlin object or a class as if it were a function in JavaScript. It's designed to mark a member function of an `external` declaration (a class or an interface) as the "invoke operator" of a JavaScript object.

When you annotate a function, every call to that function in Kotlin is translated into a direct call of the JavaScript object itself:

```
import kotlin.js.nativeInvoke

@OptIn(ExperimentalWasmJsInterop::class)
external class JsAction {
    @nativeInvoke
    operator fun invoke(data: String)
}

fun main() {
    val action = JsAction()
    action("Run task")
}
```

This is a temporary solution until stable interoperability between Kotlin/Wasm and JavaScript is designed. It may be modified or removed in future releases, and the compiler reports a warning when you use it.

For more information on the Kotlin/Wasm interoperability with JavaScript, see Interoperability with JavaScript.

Kotlin/JS

Kotlin 2.3.20 makes it possible to implement Kotlin interfaces from TypeScript and introduces experimental support for the SWC compilation platform.

Experimental

Implementing Kotlin interfaces from JavaScript/TypeScript

Kotlin 2.3.20 lifts the limitation on implementing Kotlin interfaces on the JavaScript/TypeScript side. Previously, it was only possible to export Kotlin interfaces to TypeScript as TypeScript interfaces; implementing them from TypeScript was forbidden.

Now you can implement any Kotlin interface in the following way:

```kotlin
// Kotlin
@JsExport
interface DataProcessor {
    suspend fun process(): String
}

@JsExport
fun registerProcessor(processor: DataProcessor) { ... }
```

```typescript
// TypeScript
import { DataProcessor, registerProcessor } from "my-kmp-library"

class JsonProcessor implements DataProcessor {
    readonly [DataProcessor.Symbol] = true

    async process(): Promise<string> {
        return "processed JSON data"
    }
}

registerProcessor(new JsonProcessor())
```

It's also possible to reuse Kotlin default implementations from TypeScript. Even though TypeScript has no concept of default implementations in interfaces, you can work around that by delegating to the `DefaultImpls` object:

```kotlin
// Kotlin
@JsExport
interface Logger {
    fun log(): String = "[INFO] Default log entry"
    val prefix: String get() = "LOG"
}
```

```typescript
// TypeScript
import { Logger, acceptLogger } from "my-kmp-library"

class ConsoleLogger implements Logger {
    readonly [Logger.Symbol] = true

    // Delegates to the default method implementation
    log(): string {
        return Logger.DefaultImpls.log(this);
    }

    // Delegates to the default property implementation
    get prefix(): string {
        return Logger.DefaultImpls.prefix.get(this);
    }
}

acceptLogger(new ConsoleLogger())
```

How to enable

In your build file, add the new compiler option:

```
kotlin {
    js {
        // ...
        generateTypeScriptDefinitions()
        compilerOptions {
            freeCompilerArgs.add("-Xenable-implementing-interfaces-from-typescript")
        }
    }
}
```

For more information, see `@JsExport` annotation.

Experimental

Support for SWC compilation platform

Starting with Kotlin 2.3.20, Kotlin/JS supports the SWC compilation platform. It helps transpile newer versions of JavaScript/TypeScript code into older and more compatible JavaScript code.

Delegating code conversion to an external tool allows us to reduce the number of variants produced by the Kotlin/JS compiler and speed up compiler modernization, only focusing on supporting the latest JavaScript features. Currently, the latest supported ECMAScript version is still `es2015`.

Additionally, delegating the transpilation work lets us improve the inlined JavaScript feature. Currently, it only supports ES5 syntax (this will change in 2.4.0). Supporting newer syntax while targeting lower versions would be challenging, as it would require the compiler to transpile the JS code within the inlined JS block itself. With SWC, we'll be able to add modern JS syntax, and the tool will transpile the code to the required syntax for the end-user version.

Migrating to SWC also gives you an opportunity to implement a browserlist-based DSL inside the Kotlin Gradle plugin. This allows you to declare target browsers or environments instead of specific JS versions.

How to enable

In your `gradle.properties` file, add the following option:

```
kotlin.js.delegated.transpilation=true
```

We're planning to stabilize transpilation through SWC in future Kotlin releases. After it becomes the default, the functionality of compiling multiple JS targets will be fully delegated from the Kotlin/JS compiler to the transpiler.

For more information on the SWC platform, see the official documentation.

Gradle

Kotlin 2.3.20 is compatible with new versions of Gradle and includes changes to Kotlin/JVM compilation in the Kotlin Gradle plugin.

Compatibility with Gradle 9.3.0

Kotlin 2.3.20 is fully compatible with Gradle 7.6.3 through 9.3.0. You can also use Gradle versions up to the latest Gradle release. However, be aware that doing so may result in deprecation warnings, and some new Gradle features might not work.

Improvements to binary compatibility validation in KGP

Kotlin 2.2.0 brought support for binary compatibility validation in the Kotlin Gradle plugin for the first time. Kotlin 2.3.20 adds two improvements.

First, the binary compatibility validation Gradle tasks no longer include "Legacy" in their names. We made this change because the old naming convention confused Kotlin developers:

Old name	New name
`checkLegacyAbi`	`checkKotlinAbi`
`updateLegacyAbi`	`updateKotlinAbi`
`dumpLegacyAbi`	`internalDumpKotlinAbi`

The old task names still exist in Kotlin 2.3.20 to ease the transition to the new names.

Second, if you enable binary compatibility validation in your project, Gradle now runs the `checkKotlinAbi` task automatically when you run the `check` task. Previously, Gradle didn't run the `checkKotlinAbi` task, even though the `check` task is supposed to run all verification tasks. This led to inconsistent behavior in Gradle projects.

Experimental

Kotlin/JVM compilation uses Build tools API by default

In Kotlin 2.3.20, Kotlin/JVM compilation in the Kotlin Gradle plugin uses the Build tools API (BTA) by default. This change in the internal compilation infrastructure enables faster development of build tool support for the Kotlin compiler.

If you notice any issues, share your feedback in our issue tracker.

Maven

Kotlin 2.3.20 brings an important change to make it easier to set up your Maven projects.

Simplified setup for Kotlin projects

Kotlin 2.3.20 makes it easier to set up Kotlin in Maven projects. Now Kotlin supports the automatic configuration of source roots and Kotlin's standard library.

With the new configuration, when you create a new Kotlin project with the Maven build system or introduce Kotlin to your existing Java Maven project, you don't need to manually specify source root paths or add the `kotlin-stdlib` dependency in your POM build file.

How to enable

In your `pom.xml` file, add `<extensions>true</extensions>` to the `<build><plugins>` section of the Kotlin Maven plugin:

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <version>2.4.20</version>
            <extensions>true</extensions> <!-- Add this extension -->
        </plugin>
    </plugins>
</build>
```

The new features of the `<extensions>` option here are:

- Registering `src/main/kotlin` and `src/test/kotlin` directories as source roots in case they already exist but are not specified in the plugin configuration.
- Adding the `kotlin-stdlib` dependency in case it's not explicitly defined already.

You can also opt out of the automatic addition of Kotlin's standard library. For that, add the following to the `<properties>` section:

```
<project>
    <properties>
        <!-- Disable smart defaults via property -->
        <kotlin.smart.defaults.enabled>false</kotlin.smart.defaults.enabled>
    </properties>
</project>
```

Note that this property disables not only automatic addition of the standard library, but also the registration of source root paths. Other `<extensions>` features are not affected.

For more information on configuring Kotlin Maven projects, see Configure a Maven project.

Build tools API

Kotlin 2.3.20 introduces more changes for developers who want to integrate their build systems with the Kotlin compiler using the build tools API (BTA).

Improvements to build operations

In this release, the BTA improves how build tools manage build operations. Build operations let build tools interact with the Kotlin compiler. Each build operation is an implementation of the `BuildOperation` interface.

You can now cancel build operations that implement the `CancellableBuildOperation` interface with the `cancel()` function.

The `cancel()` function works on a "best effort" basis. This means the operation isn't guaranteed to be canceled.

For example:

```
val operation = toolchains.jvm.jvmCompilationOperationBuilder(sources, destination) {}

toolchains.createBuildSession().use {
    try {
        it.executeOperation(operation.build())
    } catch (e: OperationCancelledException) {
        println("Build operation has been cancelled.")
    }
}

// ...

// From another thread:
operation.cancel()
```

In addition, build operations are now more robust because you can create them so that they can't be changed once they start. To do this, a build tool must use the builder pattern:

1. Configure the object using a mutable builder.
2. Call the `build()` function to create an immutable instance of the object.

For example:

```
fun prepareBuildOperation(toolchains: KotlinToolchains, sources: List<Path>, destination: Path):
JvmCompilationOperation {
    val builder = toolchains.jvm.jvmCompilationOperationBuilder(sources, destination)

    // Configure the operation using the builder
    builder.compilerArguments[CommonToolArguments.VERBOSE] = true
    builder[COMPILER_ARGUMENTS_LOG_LEVEL] = CompilerArgumentsLogLevel.ERROR

    // Return an immutable operation
    return builder.build()
}
```

Consistent metric collection across build tools

Before Kotlin 2.3.20, the build metrics infrastructure was centered around Gradle, which influenced parts of the infrastructure, like metric names. In addition, not all metrics were available for different compiler execution strategies.

In Kotlin 2.3.20, the BTA provides build-tool-agnostic metric collection for the JVM. The BTA also introduces a consistent set of metrics, regardless of the compiler execution strategy. Metrics that are specific to a particular compilation approach or compiler execution strategy are reported only when applicable. For example, incremental compilation metrics are only available for incremental builds, and daemon-specific metrics are only available when using the Kotlin daemon.

Build tools can now configure a `BuildMetricsCollector` object for a build operation to capture build metrics that provide the user with insight into build performance:

```
val operation =
    kotlinToolchains.jvm.jvmCompilationOperationBuilder(sources, outputDirectory)
operation[BuildOperation.METRICS_COLLECTOR] = object : BuildMetricsCollector {
    override fun collectMetric(
        name: String,
        type: BuildMetricsCollector.ValueType,
        value: Long
    ) {
        // ...
    }
}
```

Easier configuration of compiler plugins by build tools

In Kotlin 2.3.20, the BTA provides a new and simpler way for build tools to configure compiler plugins. This approach allows build tools to propagate the configuration directly to their users.

Instead of configuring compiler plugins through the command line with experimental compiler options, build tools can use the `kotlin.buildtools.api.arguments.CommonCompilerArguments.COMPILER_PLUGINS` option to configure a list of objects that represent compiler plugin configurations:

```
import org.jetbrains.kotlin.buildtools.api.KotlinToolchains
import org.jetbrains.kotlin.buildtools.api.arguments.CompilerPlugin
import org.jetbrains.kotlin.buildtools.api.arguments.CompilerPluginOption
import
org.jetbrains.kotlin.buildtools.api.arguments.CommonCompilerArguments.Companion.COMPILER_PLUGINS
import org.jetbrains.kotlin.buildtools.api.arguments.CompilerPlugin
import org.jetbrains.kotlin.buildtools.api.arguments.CompilerPluginOption
import org.jetbrains.kotlin.buildtools.api.jvm.JvmPlatformToolchain
import org.jetbrains.kotlin.buildtools.api.jvm.JvmPlatformToolchain.Companion.jvm
import org.jetbrains.kotlin.buildtools.api.jvm.operations.JvmCompilationOperation
import java.nio.file.Path

...

val toolchains: KotlinToolchains = ...
val jvmToolchain: JvmPlatformToolchain = toolchains.jvm
val operation: JvmCompilationOperation.Builder = jvmToolchain.jvmCompilationOperationBuilder(...)
val noArgPluginClasspath: List<Path> = ...
operation.compilerArguments[COMPILER_PLUGINS] = listOf(
    CompilerPlugin(
        pluginId = "org.jetbrains.kotlin.noarg",
        classpath = noArgPluginClasspath,
        rawArguments = listOf(CompilerPluginOption("annotation", "GenerateNoArgsConstructor")),
        orderingRequirements = emptySet(),
    )
)
```

Breaking changes and deprecations

This section highlights important breaking changes and deprecations. For more information about deprecations in Kotlin 2.3.0 and 2.3.20, see the Compatibility guide.

- In Kotlin 2.3.20, Kotlin/Wasm performs module initialization as part of the Wasm module's instantiation, instead of relying on external JavaScript to call an `_initialize()` function afterward. This change makes Kotlin/Wasm more independent and prepares it for the ES module integration proposal.

If you use the `@EagerInitialization` annotation, related code may fail if it runs before module initialization completes. We recommend avoiding using the `@EagerInitialization` annotation unless you truly need it.

- Experimental context receivers are no longer supported and are replaced by context parameters.
- This release takes the next step in the deprecation cycle for Intel chip-based Apple targets. Starting with Kotlin 2.3.20, we deprecate the `macosX64`, `tvosX64`, and `watchosX64` targets. We plan to completely remove support for these targets in the next Kotlin release.

  Because many third-party libraries still rely on the `iosX64` target, we'll keep it in support tier 3 for now. This means we don't guarantee CI testing, and we may not provide source and binary compatibility between different compiler releases. For more information about support tiers, see Kotlin/Native target support.
- In Kotlin 2.3.20, stricter dependency matching in Kotlin Multiplatform can cause metadata compilation failures when dependency resolution differs between common and platform source sets. See the issue in YouTrack for details and a workaround.

Documentation updates

We made the following documentation changes in the Kotlin ecosystem:

- Kotlin roadmap – See the updated list of Kotlin's priorities on language and ecosystem evolution.
- Upgrading to AGP 9 – Explore our advice for migrating your multiplatform projects with Android apps to AGP 9.
- Configure CI for a KMP app – Follow a tutorial to configure GitHub Actions for continuous integration in a multiplatform project.
- Compose UI previews – Learn how to preview composables in the IDE without running an emulator.
- Handling web resources – Find information about how to handle web resources in Compose Multiplatform.
- Setting up the viewport – Learn how to use the `ComposeViewport()` function to render your UI on an HTML canvas with Compose Multiplatform for web.
- Custom compiler plugins – Learn how compiler plugins work and what you can do if you can't find one that fits your use case.
- Application structure – Choose the best application structure for your Ktor Server app.
- HTTP request lifecycle – Learn how to cancel request processing in Ktor when a client disconnects using the HTTP request lifecycle.
- Dependency injection – Learn how to configure dependency injection in Ktor Server, with updated guidance and practical examples.
- Exposed's Spring Boot integration – Learn how to use Exposed with Spring Boot 3 and 4.

What's new in Kotlin 2.3.0

Released: December 16, 2025

The Kotlin 2.3.0 release is out! Here are the main highlights:

- **Language**: More stable and default features, unused return value checker, explicit backing fields, and changes to context-sensitive resolution.
- **Kotlin/JVM**: Support for Java 25.

- **Kotlin/Native**: Improved interop through Swift export, faster build time for release tasks, C and Objective-C library import in Beta.
- **Kotlin/Wasm**: Fully qualified names and new exception handling proposal enabled by default, as well as new compact storage for Latin-1 characters.
- **Kotlin/JS**: New experimental suspend function export, `LongArray` representation, unified companion object access, and more.
- **Gradle**: Compatibility with Gradle 9.0 and a new API for registering generated sources.
- **Compose compiler**: Stack traces for minified Android applications.
- **Standard library**: Stable time tracking functionality and improved UUID generation and parsing.

You can also find an overview of the updates in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 2.3.0 are bundled in the latest versions of IntelliJ IDEA and Android Studio. You don't need to update the Kotlin plugin in your IDE. All you need to do is change the Kotlin version to 2.3.0 in your build scripts.

See Update to a new release for details.

Language

Kotlin 2.3.0 focuses on feature stabilization, introduces a new mechanism for detecting unused return values, and improves context-sensitive resolution.

Stable features

In previous Kotlin releases, several new language features were introduced as Experimental and Beta. The following features have now graduated to Stable in Kotlin 2.3.0:

- Support for nested type aliases
- Data-flow-based exhaustiveness checks for `when` expressions

Features enabled by default

In Kotlin 2.3.0, support for `return` statements in expression bodies with explicit return types is now enabled by default.

See the full list of Kotlin language features and proposals.

Experimental

Unused return value checker

Kotlin 2.3.0 introduces the unused return value checker to help prevent ignored results. It warns you whenever an expression returns a value other than `Unit` or `Nothing` and isn't passed to a function, checked in a condition, or otherwise used.

The checker helps catch bugs where a function call produces a meaningful result that's silently dropped, which can lead to unexpected behavior or hard-to-trace issues.

> The checker ignores values returned from increment operations such as `++` and `--`.

Consider the following example:

```
fun formatGreeting(name: String): String {
    if (name.isBlank()) return "Hello, anonymous user!"
    if (!name.contains(' ')) {
        // The checker reports a warning that this result is ignored
        "Hello, " + name.replaceFirstChar(Char::titlecase) + "!"
    }
    val (first, last) = name.split(' ')
    return "Hello, $first! Or should I call you Dr. $last?"
}
```

In this example, a string is created but never used, so the checker reports it as an ignored result.

This feature is Experimental. To opt in, add the following compiler option to your build file:

Gradle

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xreturn-value-checker=check")
    }
}
```

Maven

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-Xreturn-value-checker=check</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

With this option, the checker only reports ignored results from expressions that are marked, such as most functions in the Kotlin standard library.

To mark your functions, use the `@MustUseReturnValues` annotation to mark the scope on which you want the checker to report ignored return values.

For example, you can mark an entire file:

```
// Marks all functions and classes in this file so the checker reports unused return values
@file:MustUseReturnValues

package my.project

fun someFunction(): String
```

Alternatively, you can mark a specific class:

```
// Marks all functions in this class so the checker reports unused return values
@MustUseReturnValues
class Greeter {
    fun greet(name: String): String = "Hello, $name"
}

fun someFunction(): Int = ...
```

You can also mark your entire project by adding the following compiler option to your build file:

Gradle

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xreturn-value-checker=full")
    }
}
```

Maven

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-Xreturn-value-checker=full</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

With this setting, Kotlin automatically treats your compiled files as if they are annotated with `@MustUseReturnValues`, and the checker reports all return values for your project's functions.

You can suppress warnings on specific functions by marking them with the `@IgnorableReturnValue` annotation. Annotate functions where ignoring the return value is common and expected, such as `MutableList.add`:

```
@IgnorableReturnValue
fun <T> MutableList<T>.addAndIgnoreResult(element: T): Boolean {
    return add(element)
}
```

You can suppress a warning without marking the function itself as ignorable. To do this, assign the result to a special unnamed variable with an underscore (`_`):

```
// Non-ignorable function
fun computeValue(): Int = 42

fun main() {
    // Reports a warning: result is ignored
    computeValue()

    // Suppresses the warning only at this call site with a special unused variable
    val _ = computeValue()
}
```

For more information, see the feature's KEEP.

We would appreciate your feedback in YouTrack.

Experimental

Explicit backing fields

Kotlin 2.3.0 introduces explicit backing fields – a new syntax for explicitly declaring the underlying field that holds a property's value, in contrast to the existing implicit backing fields.

You can find an overview of this feature in this video:

Watch video online.

The new explicit syntax simplifies the common backing properties pattern where a property's internal type is different from its exposed API type. For example, you might use an `ArrayList` while exposing it as a read-only `List` or a `MutableList`. Previously, this required an additional private property.

With explicit backing fields, the implementation type of the `field` is directly defined within the property's scope. This eliminates the need for a separate private property and allows the compiler to automatically perform smart casting to the backing field's type within the same private scope.

Before:

```
private val _city = MutableStateFlow<String>("")
val city: StateFlow<String> get() = _city

fun updateCity(newCity: String) {
    _city.value = newCity
}
```

After:

```
val city: StateFlow<String>
    field = MutableStateFlow("")

fun updateCity(newCity: String) {
    // Smart casting works automatically
    city.value = newCity
}
```

This feature is Experimental. To opt in, add the following compiler option to your build file:

Gradle

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xexplicit-backing-fields")
    }
}
```

Maven

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-Xexplicit-backing-fields</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

For more information, see the feature's KEEP.

We would appreciate your feedback in YouTrack.

Experimental

Changes to context-sensitive resolution

Context-sensitive resolution is still Experimental, but we are continually improving the feature based on user feedback:

- The sealed and enclosing supertypes of the current type are now considered part of the contextual scope of the search. No other supertype scopes are considered. See the KT-77823 YouTrack issue for motivation and examples.
- When type operators and equalities are involved, the compiler now reports a warning if using context-sensitive resolution makes the resolution ambiguous. This can happen, for example, when a clashing declaration of a class is imported. See the KT-77821 YouTrack issue for motivation and examples.

See the full text of the current proposal in KEEP.

Kotlin/JVM: Support for Java 25

Starting with Kotlin 2.3.0, the compiler can generate classes containing Java 25 bytecode.

Kotlin/Native

Kotlin 2.3.0 introduces improvements to the Swift export support and import of C and Objective-C libraries, as well as enhanced build times for release tasks.

Experimental

Improved interop through Swift export

Kotlin 2.3.0 further improves Kotlin's interoperability with Swift through Swift export, adding support for native enum classes and variadic function parameters.

Previously, Kotlin enums were exported as ordinary Swift classes. Now the mapping is direct, and you can use regular native Swift enums. For example:

```
// Kotlin
enum class Color(val rgb: Int) {
    RED(0xFF0000),
    GREEN(0x00FF00),
    BLUE(0x0000FF)
}

val color = Color.RED
```

```
// Swift
public enum Color: Swift.CaseIterable, Swift.LosslessStringConvertible, Swift.RawRepresentable {
    case RED, GREEN, BLUE

    var rgb: Int { get }
}
```

In addition, Kotlin's `vararg` functions are now directly mapped to Swift's variadic function parameters.

Such functions let you pass a variable number of arguments. This is useful when you don't know the number of arguments in advance or when you want to create or pass a collection without specifying its type. For example:

```
// Kotlin
fun log(vararg messages: String)
```

```
// Swift
public func log(messages: Swift.String...)
```

Generic types in variadic function parameters are not yet supported.

Beta

C and Objective-C library import is in Beta

Support for importing C and Objective-C libraries to Kotlin/Native projects is in Beta.

Full compatibility with different versions of Kotlin, dependencies, and Xcode is still not guaranteed, but the compiler now emits better diagnostics in the event of binary compatibility issues.

The import is not stable yet, and the `@ExperimentalForeignApi` opt-in annotation is still necessary when using C and Objective-C libraries in your project for certain things related to C and Objective-C interoperability, including:

- Some APIs in the `kotlinx.cinterop.*` package, required when working with native libraries or memory.
- All declarations in native libraries, except for platform libraries.

For compatibility and to prevent you from having to change your source code, the new stability status is not reflected in the annotation name.

For more information, see Stability of C and Objective-C library import.

Default explicit names in block types for Objective-C headers

Explicit parameter names in Kotlin's function types, introduced in Kotlin 2.2.20, are now the default for Objective-C headers exported from Kotlin/Native projects. These parameter names improve autocompletion suggestions in Xcode and help avoid Clang warnings.

Consider the following Kotlin code:

```
// Kotlin:
fun greetUser(block: (name: String) -> Unit) = block("John")
```

Kotlin forwards the parameter names from Kotlin function types to Objective-C block types, allowing Xcode to use them in suggestions:

```
// Objective-C:
greetUserBlock:^(NSString *name) {
    // ...
};
```

If you run into issues, you can disable explicit parameter names. To do that, add the following binary option to your `gradle.properties` file:

```
kotlin.native.binary.objcExportBlockExplicitParameterNames=false
```

Please report any problems in YouTrack.

Faster build time for release tasks

Kotlin/Native has received several performance improvements in 2.3.0. They resulted in faster build times for release tasks like `linkRelease*`, for example `linkReleaseFrameworkIosArm64`.

According to our benchmarks, release builds can be up to 40% faster, depending on the project size. These improvements are most noticeable in Kotlin Multiplatform projects targeting iOS.

For more tips on improving project compilation times, see the documentation.

Changes to Apple target support

Kotlin 2.3.0 raises the minimum supported versions of Apple targets:

- For iOS and tvOS, from 12.0 to 14.0.

- For watchOS, from 5.0 to 7.0.

According to public data, usage of older versions is already very limited. This change simplifies overall Apple target maintenance for us and opens an opportunity to support Mac Catalyst in Kotlin/Native.

If you have to keep older versions in your project, add the following lines to your build file:

```
kotlin {
    targets.withType<org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget>().configureEach {
        binaries.configureEach {
            freeCompilerArgs += "-Xoverride-konan-properties=minVersion.ios=12.0"
            freeCompilerArgs += "-Xoverride-konan-properties=minVersion.tvos=12.0"
        }
    }
}
```

Note that such a setup is not guaranteed to successfully compile and can break your app during building or at runtime.

This release also takes the next step in the deprecation cycle for Intel chip-based Apple targets.

Starting with Kotlin 2.3.0, the `macosX64`, `iosX64`, `tvosX64`, and `watchosX64` targets are demoted to support-tier 3. This means they are not guaranteed to be tested on CI, and source and binary compatibility between different compiler releases might not be provided. We plan to eventually remove support for the `x86_64` Apple targets in Kotlin 2.4.0.

For more information, see Kotlin/Native target support.

Kotlin/Wasm

Kotlin 2.3.0 enables by default fully qualified names for the Kotlin/Wasm targets, the new exception handling proposal for the `wasmWasi` target, and introduces compact storage for Latin-1 characters.

Fully qualified names enabled by default

On Kotlin/Wasm targets, fully qualified names (FQNs) were not enabled by default at runtime. You had to manually enable support for the `KClass.qualifiedName` property to use FQNs.

Only the class name (without the package) was accessible, which caused issues for code ported from the JVM to Wasm targets or for libraries that expected fully qualified names at runtime.

In Kotlin 2.3.0, the `KClass.qualifiedName` property is enabled by default on Kotlin/Wasm targets. This means that FQNs are available at runtime without any additional configuration.

Enabling FQNs by default improves code portability and makes runtime errors more informative by displaying the fully qualified name.

This change does not increase the size of the compiled Wasm binary, thanks to compiler optimizations that reduce metadata by using compact storage for Latin-1 string literals.

Compact storage for Latin-1 characters

Previously, Kotlin/Wasm stored string literal data as is, meaning every character was encoded in UTF-16. This was not optimal for text containing only, or predominantly, Latin-1 characters.

Starting with Kotlin 2.3.0, the Kotlin/Wasm compiler stores string literals containing only Latin-1 characters in UTF-8 format.

This optimization significantly reduces metadata, as experiments on JetBrains' KotlinConf application have shown. It results in:

- Up to 13% smaller Wasm binaries compared to builds without the optimization.
- Up to 8% smaller Wasm binaries even when fully qualified names are enabled, compared to earlier versions that did not store them.

This compact storage is important for web environments where download and startup times matter. Additionally, this optimization removes the size barrier that previously prevented storing fully qualified names for classes and enabling `KClass.qualifiedName` by default.

This change is enabled by default, and no further action is required.

New exception handling proposal enabled by default for `wasmWasi`

Previously, Kotlin/Wasm used the legacy exception handling proposal for all targets, including `wasmWasi`. However, most standalone WebAssembly virtual machines (VMs) are aligning with the new version of the exception handling proposal.

Starting with Kotlin 2.3.0, the new WebAssembly exception handling proposal is enabled by default for the `wasmWasi` target, ensuring better compatibility with modern WebAssembly runtimes.

For the `wasmWasi` target, the change is safe to introduce early because applications targeting it usually run in a less diverse runtime environment (often running on a single specific VM), which is typically controlled by the user, reducing the risk of compatibility issues.

The new exception handling proposal remains off by default for the `wasmJs` target. You can enable it manually by using the `-Xwasm-use-new-exception-proposal` compiler option.

Kotlin/JS

Kotlin 2.3.0 brings experimental support for exporting suspend functions to JavaScript and the `BigInt64Array` type to represent Kotlin's `LongArray` type.

With this release, you can now access companion objects inside interfaces in a unified way, use the `@JsStatic` annotation in interfaces with companion objects, the `@JsQualifier` annotation in individual functions and classes, and default exports through a new annotation, `@JsExport.Default`.

Experimental

New export of suspend function with `JsExport`

Previously, the `@JsExport` annotation did not allow exporting suspend functions (or classes and interfaces containing such functions) to JavaScript. You had to manually wrap each suspend function, which was cumbersome and prone to errors.

Starting with Kotlin 2.3.0, suspend functions can be exported directly to JavaScript using the `@JsExport` annotation.

Enabling suspend function exports reduces boilerplate and improves interoperability between Kotlin/JS and JavaScript/TypeScript (JS/TS). Kotlin's async functions can now be called directly from JS/TS without extra code.

To enable this feature, add the following compiler option to your `build.gradle.kts` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xenable-suspend-function-exporting")
    }
}
```

Once enabled, classes and functions marked with the `@JsExport` annotation can include suspend functions without additional wrappers.

They can be consumed as regular JavaScript async functions and can be overridden as an async function, as well:

```
@JsExport
open class Foo {
    suspend fun foo() = "Foo"
}
```

```
class Bar extends Foo {
    override async foo(): Promise<string> {
        return "Bar"
    }
}
```

This feature is Experimental. We would appreciate your feedback in our issue tracker, YouTrack.

Experimental

Usage of the `BigInt64Array` type to represent Kotlin's `LongArray` type

Previously, Kotlin/JS represented its `LongArray` as a JavaScript `Array<bigint>`. This approach worked but was not ideal for interoperability with JavaScript APIs that expect typed arrays.

Starting with this release, Kotlin/JS now uses JavaScript's built-in `BigInt64Array` type to represent Kotlin's `LongArray` values when compiling to JavaScript.

Using `BigInt64Array` simplifies interop with JavaScript APIs that use typed arrays. It also allows APIs that accept or return `LongArray` to be exported more naturally from Kotlin to JavaScript.

To enable this feature, add the following compiler option to your `build.gradle.kts` file:

```
kotlin {
    js {
        // ...
        compilerOptions {
            freeCompilerArgs.add("-Xes-long-as-bigint")
        }
    }
}
```

This feature is Experimental. We would appreciate your feedback in our issue tracker, YouTrack.

Unified companion object access across JS module systems

Previously, when you exported a Kotlin interface with a companion object to JavaScript/TypeScript using the `@JsExport` annotation, consuming the interface in TypeScript worked differently for ES modules compared to other module systems.

As a result, you had to adjust the consumption of the output on the TypeScript side, depending on the module system.

Consider this Kotlin code:

```
@JsExport
interface Foo {
    companion object {
        fun bar() = "OK"
    }
}
```

You had to call it differently depending on the module system:

```
// Worked for CommonJS, AMD, UMD, and no modules
Foo.bar()

// Worked for ES modules
Foo.getInstance().bar()
```

In this release, Kotlin unifies companion-object exports across all JavaScript module systems.

Now, for every module system (ES modules, CommonJS, AMD, UMD, no modules), companion objects inside interfaces are always accessed the same way (just like companions in classes):

```
// Works for all module systems
Foo.Companion.bar()
```

This improvement also fixes collection interoperability. Before, collection factory functions had to be accessed differently depending on the module system:

```
// Worked for CommonJS, AMD, UMD, and no modules
KtList.fromJsArray([1, 2, 3])

// Worked for ES modules
KtList.getInstance().fromJsArray([1, 2, 3])
```

Now, accessing collection factory functions is similar across all the module systems:

```
// Works for all module systems
KtList.fromJsArray([1, 2, 3])
```

This change reduces inconsistent behavior between module systems and avoids bugs and interoperability issues.

This feature is enabled by default.

Support for `@JsStatic` annotations in interfaces with companion objects

Previously, the `@JsStatic` annotation was not allowed inside exported interfaces with companion objects.

For example, the following code would produce an error because only members of class companion objects can be annotated with `@JsStatic`:

```
@JsExport
interface Foo {
    companion object {
        @JsStatic // Error
        fun bar() = "OK"
    }
}
```

In this case, you had to drop the `@JsStatic` annotation and access the companion from JavaScript (JS) in the following way:

```
// For all module systems
Foo.Companion.bar()
```

Now, the `@JsStatic` annotation is supported in interfaces with companion objects. You can use this annotation on such companions and call the function directly from JS, just as you would for classes:

```
// For all module systems
Foo.bar()
```

This change simplifies API consumption in JS, allows static factory methods on interfaces, and removes inconsistencies between classes and interfaces.

This feature is enabled by default.

`@JsQualifier` annotation allowed in individual functions and classes

Previously, you could only apply the `@JsQualifier` annotation at the file level, requiring all external JavaScript (JS) declarations to be placed in separate files.

Starting from Kotlin 2.3.0, you can apply the `@JsQualifier` annotation directly to individual functions and classes, just like the `@JsModule` and `@JsNonModule` annotations.

For example, you can now write the following external function code next to regular Kotlin declarations in the same file:

```
@JsQualifier("jsPackage")
private external fun jsFun()
```

This change simplifies Kotlin/JS interop, keeps your project structure cleaner, and aligns Kotlin/JS with how other platforms handle external declarations.

This feature is enabled by default.

Support for JavaScript default exports

Previously, Kotlin/JS could not generate JavaScript's default exports from Kotlin code. Instead, Kotlin/JS only generated named exports, for example:

```
export { SomeDeclaration };
```

If you required a default export, you had to use workarounds inside the compiler, such as placing the `@JsName` annotation with `default` and a space as an argument:

```
@JsExport
@JsName("default ")
class SomeDeclaration
```

Kotlin/JS now supports default exports directly through a new annotation:

```
@JsExport.Default
```

When you apply this annotation to a Kotlin declaration (class, object, function, or property), the generated JavaScript automatically includes an `export default` statement for ES modules:

```
export default HelloWorker;
```

> For module systems different from ES modules, the new `@JsExport.Default` annotation works similarly to the regular `@JsExport` annotation.

This change enables Kotlin code to conform to JavaScript conventions and is particularly important for platforms like Cloudflare Workers, or frameworks like `React.lazy`.

This feature is enabled by default. You only need to use the `@JsExport.Default` annotation.

Gradle

Kotlin 2.3.0 is fully compatible with Gradle 7.6.3 through 9.0.0. You can also use Gradle versions up to the latest Gradle release. However, be aware that doing so may result in deprecation warnings, and some new Gradle features might not work.

In addition, the minimum supported Android Gradle plugin version is now 8.2.2, and the maximum supported version is 8.13.0.

Kotlin 2.3.0 also introduces a new API for registering generated sources in your Gradle projects.

Experimental

New API for registering generated sources in Gradle projects

Kotlin 2.3.0 introduces a new Experimental API in the `KotlinSourceSet` interface, which you can use to register generated sources in your Gradle projects.

This new API is a quality-of-life improvement that helps IDEs distinguish between generated code and regular source files. The API allows IDEs to highlight the generated code differently in the UI and to trigger generation tasks when the project is imported. We are currently working on adding this support in IntelliJ IDEA. The API is also especially useful for third-party plugins or tools that generate code, such as KSP (Kotlin Symbol Processing).

For more information, see Register generated sources.

Standard library

Kotlin 2.3.0 stabilizes the new time tracking functionality, `kotlin.time.Clock` and `kotlin.time.Instant`, and adds several improvements to the Experimental UUID API.

Experimental

Improved UUID generation and parsing

Kotlin 2.3.0 introduces several improvements for the UUID API, including:

- Support for returning `null` when parsing invalid UUIDs
- New functions to generate v4 and v7 UUIDs
- Support for generating v7 UUIDs for specific timestamps

UUID support in the standard library is Experimental but planned to be stabilized in the future. To opt in, use the `@OptIn(ExperimentalUuidApi::class)` annotation or add the following compiler option to your build file:

Gradle

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-opt-in=kotlin.uuid.ExperimentalUuidApi")
    }
}
```

Maven

```
<build>
    <plugins>
        <plugin>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-maven-plugin</artifactId>
            <configuration>
                <args>
                    <arg>-opt-in=kotlin.uuid.ExperimentalUuidApi</arg>
                </args>
            </configuration>
        </plugin>
    </plugins>
</build>
```

We would appreciate your feedback in YouTrack or in the related Slack channel.

Support for returning `null` when parsing invalid UUIDs

Kotlin 2.3.0 introduces new functions to create a `Uuid` instance from a string, which return `null` instead of throwing an exception if the string isn't a valid UUID.

These functions include the following:

- `Uuid.parseOrNull()` – parses UUIDs in either hex-and-dash or hexadecimal format.
- `Uuid.parseHexDashOrNull()` – parses UUIDs only in hex-and-dash format, and returns `null` otherwise.
- `Uuid.parseHexOrNull()` – parses UUIDs only in plain hexadecimal format, and returns `null` otherwise.

Here's an example:

```
import kotlin.uuid.ExperimentalUuidApi
import kotlin.uuid.Uuid

@OptIn(ExperimentalUuidApi::class)
fun main() {
    val valid = Uuid.parseOrNull("550e8400-e29b-41d4-a716-446655440000")
    println(valid)
    // 550e8400-e29b-41d4-a716-446655440000

    val invalid = Uuid.parseOrNull("not-a-uuid")
    println(invalid)
    // null

    val hexDashValid = Uuid.parseHexDashOrNull("550e8400-e29b-41d4-a716-446655440000")
    println(hexDashValid)
    // 550e8400-e29b-41d4-a716-446655440000

    val hexDashInvalid = Uuid.parseHexDashOrNull("550e8400e29b41d4a716446655440000")
    println(hexDashInvalid)
    // null
}
```

New functions to generate v4 and v7 UUIDs

Kotlin 2.3.0 introduces two new functions for generating UUIDs: `Uuid.generateV4()` and `Uuid.generateV7()`.

Use the `Uuid.generateV4()` function to generate version 4 UUIDs, or the `Uuid.generateV7()` function to generate version 7 UUIDs.

> The `Uuid.random()` function remains unchanged and still generates version 4 UUIDs, just like `Uuid.generateV4()`.

Here's an example:

```
import kotlin.uuid.ExperimentalUuidApi
import kotlin.uuid.Uuid

@OptIn(ExperimentalUuidApi::class)
fun main() {
    // Generates a v4 UUID
    val v4 = Uuid.generateV4()
    println(v4)

    // Generates a v7 UUID
    val v7 = Uuid.generateV7()
    println(v7)

    // Generates a v4 UUID
    val random = Uuid.random()
    println(random)
}
```

Support for generating v7 UUIDs for specific timestamps

Kotlin 2.3.0 introduces the new `Uuid.generateV7NonMonotonicAt()` function, which you can use to generate a version 7 UUID for a specific moment in time.

> Unlike `Uuid.generateV7()`, `Uuid.generateV7NonMonotonicAt()` doesn't guarantee monotonic ordering, so multiple UUIDs created for the same timestamp might not be sequential.

Use this function when you need identifiers tied to a known timestamp, such as when recreating event IDs or generating database entries that reflect when something originally occurred.

For example, to create a version 7 UUID for a particular instant, use the following code:

```
import kotlin.uuid.ExperimentalUuidApi
import kotlin.uuid.Uuid
import kotlin.time.ExperimentalTime
import kotlin.time.Instant

@OptIn(ExperimentalUuidApi::class, ExperimentalTime::class)
fun main() {
    val timestamp = Instant.fromEpochMilliseconds(1577836800000) // 2020-01-01T00:00:00Z

    // Generates a v7 UUID for the specified timestamp (without monotonicity guarantees)
    val v7AtTimestamp = Uuid.generateV7NonMonotonicAt(timestamp)
    println(v7AtTimestamp)
}
```

Compose compiler: Stack traces for minified Android applications

Starting from Kotlin 2.3.0, the compiler outputs ProGuard mappings for Compose stack traces when applications are minified by R8. This expands the experimental stack traces feature that was previously only available in debuggable variants.

The release variant of stack traces contains group keys that can be used to identify composable functions in minified applications without the overhead of recording source information at runtime. The group key stack traces require your application to be built with the Compose runtime 1.10 or newer.

To enable group key stack traces, add the following line before initializing any `@Composable` content:

```
Composer.setDiagnosticStackTraceMode(ComposeStackTraceMode.GroupKeys)
```

With these stack traces enabled, the Compose runtime will append its own stack trace after a crash is captured during composition, measure, or draw passes, even when the app is minified:

```
java.lang.IllegalStateException: <message>
        at <original trace>
    Suppressed: androidx.compose.runtime.DiagnosticComposeException: Composition stack when thrown:
        at $$compose.m$123(SourceFile:1)
        at $$compose.m$234(SourceFile:1)
        ...
```

Stack traces produced by Jetpack Compose 1.10 in this mode only contain group keys that still have to be deobfuscated. This is addressed in the Kotlin 2.3.0 release with the Compose Compiler Gradle plugin, which now appends group key entries to the ProGuard mapping files produced by R8. If you see new warnings in cases when the compiler fails to create mappings for some functions, please report them to the Google IssueTracker.

The Compose Compiler Gradle plugin only creates deobfuscation mappings for the group key stack traces when R8 is enabled for the build due to dependencies on R8 mapping files.

By default, the mapping file Gradle tasks run regardless of whether you enable the traces. If they cause problems in your build, you can disable the feature entirely. Add the following property in the `composeCompiler {}` block of your Gradle configuration:

```
composeCompiler {
    includeComposeMappingFile.set(false)
}
```

There is a known issue with some code not showing up in stack traces for project files supplied by the Android Gradle plugin: KT-83099.

Please report any problems encountered to the Google IssueTracker.

Breaking changes and deprecations

This section highlights important breaking changes and deprecations. For a complete overview, see our Compatibility guide.

- Starting with Kotlin 2.3.0, the compiler no longer supports `-language-version=1.8`. There's also no support for `-language-version=1.9` on non-JVM platforms.
- Language feature sets older than 2.0 (excluding 1.9 for the JVM platform) aren't supported, but the language itself remains fully backward-compatible with Kotlin 1.0.

  If you use both the `kotlin-dsl` **and** the `kotlin("jvm")` plugin in your Gradle project, you may see a Gradle warning about an unsupported Kotlin plugin version. See our compatibility guide for guidance on migration steps.
- In Kotlin Multiplatform, support for the Android target is now available through Google's `com.android.kotlin.multiplatform.library` plugin. Migrate your projects with Android targets to the new plugin and rename your `androidTarget` blocks to `android`.
- If you continue using the Kotlin Multiplatform Gradle plugin for Android targets with Android Gradle plugin (AGP) 9.0.0 or later, you see a configuration error when using the `androidTarget` block, along with diagnostic messages that provide guidance on how to migrate. You can avoid this error by using AGP 8.x and updating to Kotlin 2.3.10, or by migrating to Google's plugin for Android targets.
- AGP 9.0.0 includes built-in support for Kotlin. Starting with Kotlin 2.3.0, you see a configuration error if you use this version of AGP with the `kotlin-android` plugin, because the plugin is no longer necessary. New diagnostic messages are available to help you migrate. If you use older AGP versions, you see a deprecation warning.
- Support for the Ant build system is no longer available.

Documentation updates

Kotlin Multiplatform documentation has moved to kotlinlang.org. Now you can switch between Kotlin and KMP docs in one place. We've also refreshed the table of contents for the language guide and introduced new navigation.

Other notable changes since the last Kotlin release:

- KMP overview – explore the Kotlin Multiplatform ecosystem on a single page.
- Kotlin Multiplatform quickstart – learn how to set up an environment with the KMP IDE plugin.
- What's new in Compose Multiplatform 1.9.3 – learn about the highlights from the latest release.
- Get started with Kotlin/JS – create a web application for the browser using Kotlin/JavaScript.
- Classes – learn the basics and best practices of using classes in Kotlin.
- Extensions – learn how you can extend classes and interfaces in Kotlin.
- Coroutines basics – explore key coroutine concepts and learn how to create your first coroutines.
- Cancellation and timeouts – learn how coroutine cancellation works and how to make coroutines respond to cancellation.
- Kotlin/Native libraries – see how to produce `klib` library artifacts.
- Kotlin Notebook overview – create interactive notebook documents with the Kotlin Notebook plugin.
- Add Kotlin to a Java project – configure a Java project to use both Kotlin and Java.
- Test Java code with Kotlin – test a mixed Java-Kotlin project with JUnit.
- New case studies page – discover how different companies apply Kotlin.

How to update to Kotlin 2.3.0

The Kotlin plugin is distributed as a bundled plugin in IntelliJ IDEA and Android Studio.

To update to the new Kotlin version, change the Kotlin version to 2.3.0 in your build scripts.

Compatibility guide for Kotlin 2.3.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 2.2 to Kotlin 2.3. This document also includes information about tool-related changes.

Basic terms

In this document, we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Drop support in `-language-version` for 1.8 and 1.9

Issue: KT-76343, KT-76344.

Component: Compiler

Incompatible change type: source

Short summary: Starting with Kotlin 2.3, the compiler no longer supports `-language-version=1.8`. Support for `-language-version=1.9` is also removed for non-JVM platforms.

Deprecation cycle:

- 2.2.0: report a warning when using `-language-version` with versions 1.8 and 1.9
- 2.3.0: raise the warning to an error for `-language-version` with version 1.8 on all platforms and for version 1.9 on non-JVM platforms

Report upper-bound constraint violation errors for inferred types with typealiases

Issue: KTLC-287

Component: Core language

Incompatible change type: source

Short summary: Previously, the compiler never reported errors about upper-bound violation constraints for the inferred types. This has been fixed in Kotlin 2.3.0 so that the error is reported consistently across all type parameters.

Deprecation cycle:

- 2.2.20: report deprecation warnings for bounds violations by implicit type arguments
- 2.3.0: raise the warning to an error for `UPPER_BOUND_VIOLATED` on implicit type arguments

Prohibit `@JvmSerializableLambda` annotation on `inline` and `crossinline` lambdas

Issue: KTLC-9

Component: Core language

Incompatible change type: source

Short summary: You can no longer apply the `@JvmSerializableLambda` annotation to `inline` or `crossinline` lambdas. These lambdas aren't serializable, so applying `@JvmSerializableLambda` had no effect.

Deprecation cycle:

- 2.1.20: report a warning when the `@JvmSerializableLambda` is applied to `inline` and `crossinline` lambdas
- 2.3.0: raise the warning to an error; this change can be enabled in progressive mode

Prohibit delegating a Kotlin interface to a Java class when the generic signatures don't match

Issue: KTLC-267

Component: Core language

Incompatible change type: source

Short summary: Kotlin 2.3.0 forbids delegation to a Java class that implements a generic interface method with a non-generic override. Previously, allowing this behavior led to type mismatches and `ClassCastException` reported at runtime. This change shifts the error from runtime to compile time.

Deprecation cycle:

- 2.1.20: report a warning
- 2.3.0: raise the warning to an error

Deprecate use of `return` in expression-bodied functions without explicit return type

Issue: KTLC-288

Component: Core language

Incompatible change type: source

Short summary: Kotlin now deprecates using `return` inside expression bodies when the function's return type isn't explicitly declared.

Deprecation cycle:

- 2.3.0: report a warning
- 2.4.0: raise the warning to an error

Prohibit inheritance from nullable supertypes introduced via typealias

Issue: KTLC-279

Component: Core language

Incompatible change type: source

Short summary: Kotlin now reports an error when attempting to inherit from a nullable typealias, which is consistent with how it already handles direct nullable supertypes.

Deprecation cycle:

- 2.2.0: report a warning
- 2.3.0: raise the warning to an error

Unify generic signature generation for top-level lambdas and call arguments

Issue: KTLC-277

Component: Reflection

Incompatible change type: behavioral

Short summary: Kotlin 2.3.0 uses the same type-checking logic for top-level lambdas as it does for lambdas passed as call arguments, ensuring consistent generic signature generation across both cases.

Deprecation cycle:

- 2.3.0: introduce the new behavior; not applicable in progressive mode

Prohibit reified type parameters from being inferred as intersection types

Issue: KTLC-13

Component: Core language

Incompatible change type: source

Short summary: Kotlin 2.3.0 prohibits situations where a reified type parameter is inferred to an intersection type, as this could lead to incorrect runtime behavior.

Deprecation cycle:

- 2.1.0: report a warning when a reified type parameter is inferred as an intersection type
- 2.3.0: raise the warning to an error

Prohibit exposing less-visible types through type parameter bounds

Issue: KTLC-275

Component: Core language

Incompatible change type: source

Short summary: Kotlin 2.3.0 forbids using type parameter bounds that expose types with more restrictive visibility than the function or declaration itself, aligning the rules for functions with those already applied to classes.

Deprecation cycle:

- 2.1.0: report a warning on the problematic type parameter bound
- 2.3.0: raise the warning to an error

Standard library

Deprecate Char-to-number conversions and introduce explicit digit and code APIs

Issue: KTLC-321

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Kotlin 2.3.0 deprecates `Char.toX()` and `X.toChar()` conversions for numeric types and introduces new, explicit APIs for accessing a character's code and digit value.

Deprecation cycle:

- 1.4.30: introduce new functions as Experimental
- 1.5.0: promote the new functions to Stable; report warnings for old functions with suggestions for replacements
- 2.3.0: raise the warnings to errors

Deprecate `Number.toChar()` function

Issue: KT-56822

Component: kotlin-stdlib

Incompatible change type: source

Short summary: The `Number.toChar()` function is deprecated. Use `toInt().toChar()` or the `Char` constructor instead.

Deprecation cycle:

- 1.9.0: report a warning when using the `Number.toChar()` function
- 2.3.0: raise the warning to an error

Deprecate `String.subSequence(start, end)` function

Issue: KTLC-282

Component: kotlin-stdlib

Incompatible change type: source

Short summary: The `String.subSequence(start, end)` function is deprecated. Use the `String.subSequence(startIndex, endIndex)` function instead.

Deprecation cycle:

- 1.0: report a warning when using `String.subSequence(start, end)`
- 2.3.0: raise the warning to an error

Deprecate `kotlin.io.createTempDirectory()` and `kotlin.io.createTempFile()` functions

Issue: KTLC-281

Component: kotlin-stdlib

Incompatible change type: source

Short summary: The `kotlin.io.createTempDirectory()` and `kotlin.io.createTempFile()` functions are deprecated. Use the `kotlin.io.path.createTempDirectory()` and `kotlin.io.path.createTempFile()` functions instead.

Deprecation cycle:

- 1.4.20: report a warning when using `kotlin.io.createTempDirectory()` and `kotlin.io.createTempFile()` functions
- 2.3.0: raise the warning to an error

Hide `InputStream.readBytes(Int)` function

Issue: KTLC-280

Component: kotlin-stdlib

Incompatible change type: source

Short summary: After being deprecated for a long time, the `InputStream.readBytes(estimatedSize: Int = DEFAULT_BUFFER_SIZE): ByteArray` function is now hidden.

Deprecation cycle:

- 1.3.0: report a warning
- 1.5.0: raise the warning to an error
- 2.3.0: hide the function

Unify Kotlin/Native stack trace printing with other platforms

Issue: KT-81431

Component: Kotlin/Native

Incompatible change type: behavioral

Short summary: When formatting an exception stack trace, additional causes aren't printed if the same exception cause has already been printed.

Deprecation cycle:

- 2.3.20: Unify Kotlin/Native exception stack trace formatting with other Kotlin platforms

Correct `Iterable<T>.intersect()` and `Iterable<T>.subtract()` behavior

Issue: KTLC-268

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: The `Iterable<T>.intersect()` and `Iterable<T>.subtract()` functions now test membership for each receiver element before adding it to the result set. The result set compares elements using `Any::equals`, ensuring correct results even when the argument collection uses referential equality (for example, `IdentityHashMap.keys`).

Deprecation cycle:

- 2.3.0: enable the new behavior

Tools

Unsupported KGP version warning when using `kotlin-dsl` and `kotlin("jvm")` plugins

Issue: KT-79851

Component: Gradle

Incompatible change type: behavioral

Short summary: In Kotlin 2.3, if you use both the `kotlin-dsl` **and** the `kotlin("jvm")` plugin in your Gradle project, you may see a Gradle warning about an unsupported Kotlin Gradle plugin (KGP) version.

Migration steps:

In general, we don't recommend using both the `kotlin-dsl` and the `kotlin("jvm")` plugins in the same Gradle project. This setup isn't supported.

For convention plugins, precompiled script plugins or any other form of unpublished build logic, you have three options:

1. Don't apply the `kotlin("jvm")` plugin explicitly. Instead, let the `kotlin-dsl` plugin automatically provide a compatible KGP version.
2. If you want to apply the `kotlin("jvm")` plugin explicitly, use the `embeddedKotlinVersion` constant to specify the embedded Kotlin version.

   To upgrade the embedded Kotlin and language versions, update your Gradle version. You can find compatible Gradle versions in Gradle's Compatibility Notes for Kotlin.
3. Don't use the `kotlin-dsl` plugin. This may be more appropriate for binary plugins that aren't tied to a specific Gradle version.

As a last resort, you can configure your project to use language version 2.1 or higher, which overrides the conflicting behavior of the `kotlin-dsl` plugin. However, we strongly recommend not doing so.

If you experience difficulties during migration, reach out in the #gradle channel in our Slack for support.

Deprecation cycle:

- 2.3.0: introduce a diagnostic that detects when the `kotlin-dsl` plugin is used with an incompatible language or API version of the compiler

Deprecate `kotlin-android` plugin for AGP versions 9.0.0 and later

Issue: KT-81199

Component: Gradle

Incompatible change type: source

Short summary: In Kotlin 2.3.0, the `org.jetbrains.kotlin.android` plugin is deprecated when using Android Gradle plugin (AGP) versions 9.0.0 or later. Starting with AGP 9.0.0, AGP provides built-in support for Kotlin, so the `kotlin-android` plugin is no longer required.

Deprecation cycle:

- 2.3.0: report a warning when the `kotlin-android` plugin is used with AGP versions 9.0.0 or later, and both the `android.builtInKotlin` and `android.newDsl=false` Gradle properties are set to `false`

Deprecate `testApi` configuration

Issue: KT-63285

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 2.3.0 deprecates the `testApi` configuration. This configuration exposed test dependencies and sources to other modules, but Gradle doesn't support this behavior.

Migration options: Replace any instances of `testApi()` with `testImplementation()`, and do the same for other variants. For example, replace `kotlin.sourceSets.commonTest.dependencies.api()` with `kotlin.sourceSets.commonTest.dependencies.implementation()`.

For Kotlin/JVM projects, consider using Gradle's test fixtures instead. If you'd like to see support for test fixtures in multiplatform projects, share your use case in YouTrack.

Deprecation cycle:

- 2.3.0: report a warning

Deprecate `createTestExecutionSpec()` function

Issue: KT-75449

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 2.3.0 deprecates the `createTestExecutionSpec()` function in the `KotlinJsTestFramework` interface since it is no longer used.

Deprecation cycle:

- 2.2.20: report a warning
- 2.3.0: raise the warning to an error
- 2.4.0: remove the function

Remove `closureTo()`, `createResultSet()`, and `KotlinToolingVersionOrNull()` functions

Issue: KT-64273

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 2.3.0 removes the `closureTo()`, `createResultSet()` functions from the `closure` DSL since they are no longer used. In addition, the `KotlinToolingVersionOrNull()` function is removed. Use the `KotlinToolingVersion()` function instead.

Deprecation cycle:

- 1.7.20: report an error
- 2.3.0: remove the functions

Deprecate the `ExtrasProperty` API

Issue: KT-74915

Component: Gradle

Incompatible change type: source

Short summary: The `ExtrasProperty` API, which has been deprecated since Kotlin 2.0.0, is now internalized in Kotlin 2.3.0. Use Gradle's `ExtraPropertiesExtension` API as an alternative.

Deprecation cycle:

- 2.0.0: report a warning
- 2.1.0: raise the warning to an error
- 2.3.0: make the API internal

Deprecate `HasKotlinDependencies` in `KotlinCompilation`

Issue: KT-67290

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 2.3.0 deprecates the `HasKotlinDependencies` interface in `KotlinCompilation`. Dependency-related APIs are now exposed through the `KotlinSourceSet` interface instead.

Deprecation cycle:

- 2.3.0: report a warning

Deprecate npm and Yarn package manager internal functions and properties

Issue: KT-81009

Component: Gradle

Incompatible change type: source

Short summary: The following functions and properties related to the npm and Yarn package managers are deprecated:

- `CompositeDependency.dependencyName`, `CompositeDependency.dependencyVersion`, `CompositeDependency.includedBuildDir`.
- `KotlinNpmInstallTask.Companion.NAME`.
- `LockCopyTask.Companion.STORE_PACKAGE_LOCK_NAME`, `LockCopyTask.Companion.RESTORE_PACKAGE_LOCK_NAME`, `LockCopyTask.Companion.UPGRADE_PACKAGE_LOCK`.
- `Npm.npmExec()`.
- `NpmProject.require()`, `NpmProject.useTool()`.
- `PublicPackageJsonTask.jsIrCompilation`.
- `YarnBasics.yarnExec()`.
- `YarnPlugin.Companion.STORE_YARN_LOCK_NAME`, `YarnPlugin.Companion.RESTORE_YARN_LOCK_NAME`, `YarnPlugin.Companion.UPGRADE_YARN_LOCK`.
- `YarnSetupTask.Companion.NAME`.

Deprecation cycle:

- 2.2.0 and 2.2.20: report warnings when using these functions or properties
- 2.3.0: raise the warnings to errors
- 2.4.0: remove the functions and properties

Deprecate support for PhantomJS

Issue: KT-76019

Component: Gradle

Incompatible change type: source

Short summary: Since PhantomJS is no longer maintained, Kotlin 2.3.0 deprecates the `karmaPhantomjsLauncher` property in the `NpmVersions` API.

Deprecation cycle:

- 2.3.0: report a warning

Prohibit subclassing of classes that set up test runs or JavaScript runtime

Issue: KT-75869, KT-81007

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 2.3.0 prohibits subclassing the following classes:

- `KotlinTest`
- `KotlinNativeTest`
- `KotlinJsTest`
- `KotlinJsIrTarget`
- `KotlinNodeJsIr`
- `KotlinD8Ir`
- `KotlinKarma`
- `KotlinMocha`
- `KotlinWebpack`
- `TypeScriptValidationTask`
- `YarnRootExtension`

These classes were never intended to be subclassed. All use cases for subclassing should now be covered by the configuration blocks provided by the Kotlin Gradle plugin DSL. If the existing APIs for these tasks don't meet your needs for setting up test runs or the JavaScript runtime, share your feedback in YouTrack.

Deprecation cycle:

- 2.2.0: report a warning for code that creates subclasses from these classes
- 2.3.0: raise the warnings to errors
- 2.4.0: remove the APIs

Deprecate `ExperimentalWasmDsl` annotation class

Issue: KT-81005

Component: Gradle

Incompatible change type: source

Short summary: The `ExperimentalWasmDsl` annotation class is deprecated since the functionality has moved to the `kotlin-plugin-annotations` module.

Deprecation cycle:

- 2.0.20: report a warning
- 2.3.0: raise the warning to an error
- 2.4.0: remove the annotation class

Deprecate `ExperimentalDceDsl` annotation class

Issue: KT-81008

Component: Gradle

Incompatible change type: source

Short summary: The `ExperimentalDceDsl` annotation class isn't used anymore, so it's been deprecated.

Deprecation cycle:

- 2.2.0: report a warning
- 2.3.0: raise the warning to an error
- 2.4.0: remove the annotation class

Deprecate JavaScript utilities

Issue: KT-81010

Component: Gradle

Incompatible change type: source

Short summary: The following functions and properties are only used internally, so they've been deprecated:

- `JsIrBinary.generateTs`
- `KotlinJsIrLink.mode`
- `NodeJsSetupTask.Companion.NAME`
- `Appendable.appendConfigsFromDir()`
- `ByteArray.toHex()`
- `FileHasher.calculateDirHash()`
- `String.jsQuoted()`

Deprecation cycle:

- 2.2.0: report a warning when the `KotlinJsIrLink.mode` property is used
- 2.2.0: report a warning when the `NodeJsSetupTask.Companion.NAME` property and functions are used
- 2.2.20: report a warning when the `JsIrBinary.generateTs` property is used
- 2.3.0: raise the warnings to errors
- 2.4.0: remove the APIs

Deprecate migrated D8 and Binaryen properties

Issue: KT-81006

Component: Gradle

Incompatible change type: source

Short summary: The following properties are deprecated because they've been migrated from the `org.jetbrains.kotlin.gradle.targets.js` package to the `org.jetbrains.kotlin.gradle.targets.wasm` package:

- `binaryen.BinaryenEnvSpec`
- `binaryen.BinaryenExtension`
- `binaryen.BinaryenPlugin`
- `binaryen.BinaryenRootPlugin`
- `BinaryenSetupTask.Companion.NAME`
- `d8.D8EnvSpec`
- `d8.D8Plugin`
- `D8SetupTask.Companion.NAME`

Deprecation cycle:

- 2.2.0: report a warning
- 2.3.0: raise the warning to an error
- 2.4.0: remove the properties

Deprecate `create()` function in `NodeJsExec` DSL

Issue: KT-81004

Component: Gradle

Incompatible change type: source

Short summary: The `create()` function in the companion object of the `NodeJsExec` DSL is deprecated. Use the `register()` function instead.

Deprecation cycle:

- 2.1.20: report a warning
- 2.3.0: raise the warning to an error
- 2.4.0: remove the function

Deprecate properties in `kotlinOptions` DSL

Issue: KT-76720

Component: Gradle

Incompatible change type: source

Short summary: The ability to configure compiler options through the `kotlinOptions` DSL and the related `KotlinCompile<KotlinOptions>` task interface has been deprecated in favor of the new `compilerOptions` DSL since Kotlin 2.2.0. Kotlin 2.3.0 continues the deprecation cycle for all properties in the `kotlinOptions` interface. To migrate, use the `compilerOptions` DSL to configure compiler options. For guidance on the migration, see Migrate from `kotlinOptions {}` to `compilerOptions {}`.

Deprecation cycle:

- 2.0.0: report a warning for `kotlinOptions` DSL
- 2.2.0: raise the warning to an error and deprecate all properties in `kotlinOptions`
- 2.3.0: raise the warning to an error for all properties in `kotlinOptions`

Deprecate `kotlinArtifacts` API

Issue: KT-77066

Component: Gradle

Incompatible change type: source

Short summary: The experimental `kotlinArtifacts` API is deprecated. Use the current DSL available in the Kotlin Gradle plugin to build final native binaries. If it's not sufficient for migration, leave a comment in this YouTrack issue.

Deprecation cycle:

- 2.2.0: report a warning when the `kotlinArtifacts` API is used
- 2.3.0: raise this warning to an error
- 2.4.0: remove the API

Remove `kotlin.mpp.resourcesResolutionStrategy` Gradle property

Issue: KT-74955

Component: Gradle

Incompatible change type: source

Short summary: Previously the `kotlin.mpp.resourcesResolutionStrategy` Gradle property was deprecated because it wasn't used. In Kotlin 2.3.0, the Gradle property is removed completely.

Deprecation cycle:

- 2.2.0: report a configuration-time diagnostic
- 2.3.0: remove the Gradle property

Deprecated old mode of multiplatform IDE import

Issue: KT-61127

Component: Gradle

Incompatible change type: source

Short summary: Before Kotlin 2.3.0, we supported multiple modes of multiplatform IDE import. Now, the older mode is deprecated, leaving only one mode available. Previously, the old mode was enabled using the `kotlin.mpp.import.enableKgpDependencyResolution=false` Gradle property. Using this property now triggers a deprecation warning.

Deprecation cycle:

- 2.3.0: report a warning when the `kotlin.mpp.import.enableKgpDependencyResolution=false` Gradle property is used

Remove properties to disable precise compilation backup

Issue: KT-81038

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 1.9.0 introduced an experimental optimization for incremental compilation called precise compilation backup. After successful testing, this optimization was enabled by default in Kotlin 2.0.0. Kotlin 2.3.0 removes the `kotlin.compiler.preciseCompilationResultsBackup` and `kotlin.compiler.keepIncrementalCompilationCachesInMemory` Gradle properties that opt out of this optimization.

Deprecation cycle:

- 2.1.20: report a warning
- 2.3.0: remove the properties

Deprecate `destinationDir` in `CInteropProcess`

Issue: KT-74910

Component: Gradle

Incompatible change type: source

Short summary: The `destinationDir` property in the `CInteropProcess` task is deprecated. Use the `CInteropProcess.destinationDirectory.set()` function instead.

Deprecation cycle:

- 2.1.0: report a warning when the `destinationDir` property is used
- 2.2.0: raise this warning to an error
- 2.3.0: hide the `destinationDir` property

Deprecate `konanVersion` in `CInteropProcess`

Issue: KT-74911

Component: Gradle

Incompatible change type: source

Short summary: The `konanVersion` property in the `CInteropProcess` task is deprecated. Use `CInteropProcess.kotlinNativeVersion` instead.

Deprecation cycle:

- 2.1.0: report a warning when the `konanVersion` property is used
- 2.2.0: raise this warning to an error
- 2.3.0: hide the `konanVersion` property

Remove `KotlinCompile.classpathSnapshotProperties` properties

Issue: KT-76177

Component: Gradle

Incompatible change type: source

Short summary: The `kotlin.incremental.useClasspathSnapshot` Gradle property was removed in Kotlin 2.2.0. In Kotlin 2.3.0, the following properties are also removed:

- `KotlinCompile.classpathSnapshotProperties.useClasspathSnapshot`
- `KotlinCompile.classpathSnapshotProperties.classpath`

Deprecation cycle:

- 2.0.20: deprecate the `kotlin.incremental.useClasspathSnapshot` property with a warning
- 2.2.0: remove the `kotlin.incremental.useClasspathSnapshot` property
- 2.3.0: remove the `KotlinCompile.classpathSnapshotProperties.useClasspathSnapshot` and `KotlinCompile.classpathSnapshotProperties.classpath` properties

Deprecate `getPluginArtifactForNative()` function

Issue: KT-78870

Component: Gradle

Incompatible change type: source

Short summary: In Kotlin 2.2.20, the `getPluginArtifactForNative()` function was deprecated. Use the `getPluginArtifact()` function instead.

Deprecation cycle:

- 2.2.20: report a warning
- 2.3.0: raise the warning to an error
- 2.4.0: remove the function

Change the approach to registering all generated sources

Issue: KT-45161

Component: Gradle

Incompatible change type: source

Short summary: Kotlin 2.3.0 introduces a new Experimental API in the `KotlinSourceSet` interface that lets you register generated sources in a Gradle project. Previously, you could use the `kotlin` property to access all generated sources. Starting with Kotlin 2.3.0, if your plugin or build logic needs access to all generated sources, use the `allKotlinSources` property instead.

Migration advice:

- To register generated sources, use the `generatedKotlin` property.
- To access all sources, including non-generated sources, use the `allKotlinSources` property.

Deprecate `kotlin.publishJvmEnvironmentAttribute` property

Issue: KT-83678

Component: Gradle

Incompatible change type: source

Short summary: In Kotlin 2.3.20, the `kotlin.publishJvmEnvironmentAttribute` property is deprecated. This property allowed disabling the publication of the `org.gradle.jvm.environment` attribute for multiplatform libraries. Starting with Kotlin 2.0.20, `org.gradle.jvm.environment` is published by default to ensure conventional dependency resolution.

Deprecation cycle:

- 2.3.20: report a warning
- 2.4.0: remove the property

Deprecate `CleanableStore` interface and `CleanDataTask` class

Issue: KT-78104

Component: Gradle

Incompatible change type: source

Short summary: The `CleanableStore` interface and `CleanDataTask` class are deprecated since they are no longer used.

Deprecation cycle:

- 2.3.20: report a warning
- 2.4.20: raise the warning to an error

Deprecate `kotlin.kmp.isolated-projects.support` Gradle property

Issue: KT-79257

Component: Gradle

Incompatible change type: source

Short summary: Since multiplatform projects are compatible with isolated projects by default and there are no other options, the `kotlin.kmp.isolated-projects.support` Gradle property is deprecated.

Deprecation cycle:

- 2.3.20: report a warning

Deprecate `kotlin.mpp.enableKotlinToolingMetadataArtifact` Gradle property

Issue: KT-79924

Component: Gradle

Incompatible change type: source

Short summary: Since the `kotlin-tooling-metadata.json` artifact is now always generated for multiplatform projects, the `kotlin.mpp.enableKotlinToolingMetadataArtifact` Gradle property is deprecated.

Deprecation cycle:

- 2.3.20: report a warning
- 2.4.0: remove support

Deprecate `LanguageSettings.enableLanguageFeature` DSL

Issue: KT-82323, KT-82847

Component: Gradle

Incompatible change type: source

Short summary: The `LanguageSettings.enableLanguageFeature` DSL exposed an internal compiler configuration only intended for Kotlin compiler tests. Therefore, the DSL is deprecated.

Deprecation cycle:

- 2.3.20: report a warning when using `LanguageSettings.enableLanguageFeature`
- 2.4.0: raise the warning to an error

Deprecate "out of process" compiler execution strategy

Issue: KT-83125

Component: Gradle

Incompatible change type: source

Short summary: The "out of process" compiler execution strategy is not supported by the Build tools API and is the slowest strategy available. In Kotlin 2.3.20, the strategy is deprecated in favor of "daemon" and "in process" compiler execution strategies.

Deprecation cycle:

- 2.3.20: report a warning
- 2.4.0: remove the "out of process" compiler execution strategy

Build tool removal

Remove support for Ant

Issue: KT-75875

Component: Ant

Short summary: Kotlin 2.3.0 removes support for Ant as a build tool. Use Gradle or Maven instead.

Deprecation cycle:

- 2.2.0: report a warning
- 2.3.0: remove support

What's new in Kotlin 2.2.20

Released: September 10, 2025

The Kotlin 2.2.20 release is out, delivering important changes for web development. Kotlin/Wasm is now Beta, with improvements to exception handling in JavaScript interop, npm dependency management, built-in browser debugging support, and a new shared source set for `js` and `wasmJs` targets.

Additionally, here are some main highlights:

- **Kotlin Multiplatform**: Swift export available by default, stable cross-platform compilation for Kotlin libraries, and a new approach for declaring common dependencies.
- **Language**: Improved overload resolution when passing lambdas to overloads with suspend function types.
- **Kotlin/Native**: Support for Xcode 26, stack canaries, and smaller binary size for release binaries.
- **Kotlin/JS**: `Long` values compiled into JavaScript `BigInt`.

Compose Multiplatform for web goes Beta. Learn more in our blog post.

You can also find a short overview of the updates in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugin that supports Kotlin 2.2.20 is bundled in the latest versions of IntelliJ IDEA and Android Studio. To update, all you need to do is change the Kotlin version to 2.2.20 in your build scripts.

See Update to a new release for details.

Language

In Kotlin 2.2.20, you can try out upcoming language features planned for Kotlin 2.3.0, including improved overload resolution when passing lambdas to overloads with `suspend` function types and support for `return` statements in expression bodies with explicit return types. This release also includes improvements to exhaustiveness checks for `when` expressions, reified `Throwable` catches, and Kotlin contracts.

Improved overload resolution for lambdas with `suspend` function types

Previously, overloading a function with both a regular function type and a `suspend` function type caused an ambiguity error when passing a lambda. You could work around this error with an explicit type cast, but the compiler incorrectly reported a `No cast needed` warning:

```
// Defines two overloads
fun transform(block: () -> Int) {}
fun transform(block: suspend () -> Int) {}

fun test() {
    // Fails with overload resolution ambiguity
    transform({ 42 })

    // Uses an explicit cast, but the compiler incorrectly reports
    // a "No cast needed" warning
    transform({ 42 } as () -> Int)
}
```

With this change, when you define both a regular and a `suspend` function type overload, a lambda without a cast resolves to the regular overload. Use the `suspend` keyword to resolve to the suspend overload explicitly:

```
// Resolves to transform(() -> Int)
transform({ 42 })

// Resolves to transform(suspend () -> Int)
transform(suspend { 42 })
```

This behavior will be enabled by default in Kotlin 2.3.0. To test it now, set your language version to `2.3` using the following compiler option:

```
-language-version 2.3
```

Or configure it in your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        languageVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_2_3)
    }
}
```

We would appreciate your feedback in our issue tracker, YouTrack.

Support for `return` statements in expression bodies with explicit return types

Previously, using `return` in an expression body caused a compiler error because it could cause the function's return type to be inferred as `Nothing`.

```
fun example() = return 42
// Error: Returns are prohibited for functions with an expression body
```

With this change, you can now use `return` in expression bodies as long as the return type is written explicitly:

```
// Specifies the return type explicitly
fun getDisplayNameOrDefault(userId: String?): String = getDisplayName(userId ?: return "default")

// Fails because it doesn't specify the return type explicitly
fun getDisplayNameOrDefault(userId: String?) = getDisplayName(userId ?: return "default")
```

Similarly, `return` statements inside lambdas and nested expressions in functions with expression bodies used to compile unintentionally. Kotlin now supports these cases as long as the return type is specified explicitly. Cases without an explicit return type will be deprecated in Kotlin 2.3.0:

```
// Return type isn't explicitly specified, and the return statement is inside a lambda
// which will be deprecated
fun returnInsideLambda() = run { return 42 }

// Return type isn't explicitly specified, and the return statement is inside the initializer
// of a local variable, which will be deprecated
fun returnInsideIf() = when {
    else -> {
        val result = if (someCondition()) return "" else "value"
        result
    }
}
```

This behavior will be enabled by default in Kotlin 2.3.0. To test it now, set your language version to `2.3` using the following compiler option:

```
-language-version 2.3
```

Or configure it in your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        languageVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_2_3)
    }
}
```

We would appreciate your feedback in our issue tracker, YouTrack.

Experimental

Data-flow-based exhaustiveness checks for `when` expressions

Kotlin 2.2.20 introduces **data-flow-based** exhaustiveness checks for `when` expressions. Previously, the compiler's checks were limited to the `when` expression itself, often forcing you to add a redundant `else` branch. With this update, the compiler now tracks prior condition checks and early returns, so you can remove redundant `else` branches.

For example, the compiler now recognizes that the function returns when the `if` condition is met, so the `when` expression only needs to handle the remaining cases:

```
enum class UserRole { ADMIN, MEMBER, GUEST }

fun getPermissionLevel(role: UserRole): Int {
    // Covers the Admin case outside of the when expression
    if (role == UserRole.ADMIN) return 99

    return when (role) {
        UserRole.MEMBER -> 10
        UserRole.GUEST -> 1
        // You no longer have to include this else branch
        // else -> throw IllegalStateException()
    }
}
```

This feature is Experimental. To enable it, add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xdata-flow-based-exhaustiveness")
    }
}
```

Experimental

Support for reified types in `catch` clauses

In Kotlin 2.2.20, the compiler now allows using reified generic type parameters in `catch` clauses of `inline` functions.

Here's an example:

```
inline fun <reified ExceptionType : Throwable> handleException(block: () -> Unit) {
    try {
        block()
        // This is now allowed after the change
    } catch (e: ExceptionType) {
        println("Caught specific exception: ${e::class.simpleName}")
    }
}

fun main() {
    // Tries to perform an action that might throw an IOException
    handleException<java.io.IOException> {
        throw java.io.IOException("File not found")
    }
    // Caught specific exception: IOException
}
```

Previously, attempting to catch a reified `Throwable` type in an `inline` function would result in an error.

This behavior will be enabled by default in Kotlin 2.4.0. To use it now, add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xallow-reified-type-in-catch")
    }
}
```

The Kotlin team is grateful to external contributor Iven Krall for their contribution.

Experimental

Improved Kotlin contracts

Kotlin 2.2.20 introduces several improvements to Kotlin contracts, including:

- Support for generics in contract type assertions.
- Support for contracts inside property accessors and specific operator functions.
- Support for the `returnsNotNull()` function in contracts as a way to ensure a non-null return value when a condition is met.
- New `holdsIn` keyword, allowing you to assume conditions are true when passed inside lambdas.

These improvements are Experimental. To opt in, you still need to use the `@OptIn(ExperimentalContracts::class)` annotation when declaring contracts. The `holdsIn` keyword and the `returnsNotNull()` function also need the `@OptIn(ExperimentalExtendedContracts::class)` annotation.

To use these improvements, you also need to add the compiler options described in each section below.

We would appreciate your feedback in our issue tracker.

Support for generics in contract type assertions

You can now write contracts that perform type assertions on generic types:

```
import kotlin.contracts.*

sealed class Failure {
    class HttpError(val code: Int) : Failure()
    // Insert other failure types here
}

sealed class Result<out T, out F : Failure> {
    class Success<T>(val data: T) : Result<T, Nothing>()
    class Failed<F : Failure>(val failure: F) : Result<Nothing, F>()
}

@OptIn(ExperimentalContracts::class)
// Uses a contract to assert a generic type
fun <T, F : Failure> Result<T, F>.isHttpError(): Boolean {
    contract {
        returns(true) implies (this@isHttpError is Result.Failed<Failure.HttpError>)
    }
    return this is Result.Failed && this.failure is Failure.HttpError
}
```

In this example, the contract performs a type assertion on the `Result` object, allowing the compiler to safely smart cast it to the asserted generic type.

This feature is Experimental. To opt in, add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xallow-contracts-on-more-functions")
    }
}
```

Support for contracts inside property accessors and specific operator functions

You can now define contracts inside property accessors and specific operator functions. This lets you use contracts on more types of declarations, making them more flexible.

For example, you can use a contract inside a getter to enable smart casting for a receiver object:

```
import kotlin.contracts.*

val Any.isHelloString: Boolean
    get() {
        @OptIn(ExperimentalContracts::class)
        // Enables smart casting the receiver to String when the getter returns true
        contract { returns(true) implies (this@isHelloString is String) }
        return "hello" == this
    }

fun printIfHelloString(x: Any) {
    if (x.isHelloString) {
        // Prints the length after the smart cast of the receiver to String
        println(x.length)
        // 5
    }
}
```

Additionally, you can use contracts in the following operator functions:

- `invoke`
- `contains`
- `rangeTo`, `rangeUntil`
- `componentN`
- `iterator`
- `unaryPlus`, `unaryMinus`, `not`
- `inc`, `dec`

Here's an example of using a contract in an operator function to ensure the initialization of a variable inside a lambda:

```
import kotlin.contracts.*

class Runner {
    @OptIn(ExperimentalContracts::class)
    // Enables initialization of variables assigned inside the lambda
    operator fun invoke(block: () -> Unit) {
        contract {
            callsInPlace(block, InvocationKind.EXACTLY_ONCE)
        }
        block()
    }
}

fun testOperator(runner: Runner) {
    val number: Int
    runner {
        number = 1
    }
    // Prints the value after definite initialization guaranteed by the contract
    println(number)
    // 1
}
```

This feature is Experimental. To opt in, add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xallow-contracts-on-more-functions")
    }
}
```

Support for the `returnsNotNull()` function in contracts

Kotlin 2.2.20 introduces the `returnsNotNull()` function for contracts. You can use this function to ensure that a function returns a non-null value when a specific condition is met. This simplifies your code by replacing separate nullable and non-nullable function overloads with a single, concise function:

```
import kotlin.contracts.*

@OptIn(ExperimentalContracts::class, ExperimentalExtendedContracts::class)
fun decode(encoded: String?): String? {
    contract {
        // Guarantees a non-null return value when the input is non-null
        (encoded != null) implies (returnsNotNull())
    }
    if (encoded == null) return null
    return java.net.URLDecoder.decode(encoded, "UTF-8")
}

fun useDecodedValue(s: String?) {
    // Uses a safe call since the return value may be null
    decode(s)?.length
    if (s != null) {
        // Treats the return value as non-null after the smart cast
        decode(s).length
    }
}
```

In this example, the contract in the `decode()` function allows the compiler to smart-cast its return value when the input is non-null, removing the need for extra null checks or multiple overloads.

This feature is Experimental. To opt in, add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xallow-condition-implies-returns-contracts")
    }
}
```

New `holdsIn` keyword

Kotlin 2.2.20 introduces the new `holdsIn` keyword for contracts. You can use it to ensure that a boolean condition is assumed to be `true` inside a specific lambda. This lets you build DSLs with conditional smart casts using contracts.

Here's an example:

```
import kotlin.contracts.*

@OptIn(ExperimentalContracts::class, ExperimentalExtendedContracts::class)
fun <T> T.alsoIf(condition: Boolean, block: (T) -> Unit): T {
    contract {
        // Declares that the lambda runs at most once
        callsInPlace(block, InvocationKind.AT_MOST_ONCE)
        // Declares that the condition is assumed to be true inside the lambda
        condition holdsIn block
    }
    if (condition) block(this)
    return this
}

fun useApplyIf(input: Any) {
    val result = listOf(1, 2, 3)
        .first()
        .alsoIf(input is Int) {
            // The input parameter is smart cast to Int inside the lambda
            // Prints the sum of input and first list element
            println(input + it)
            // 2
        }
        .toString()
}
```

This feature is Experimental. To opt in, add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xallow-holdsin-contract")
    }
}
```

Experimental

Kotlin/JVM: Support `invokedynamic` with `when` expressions

In Kotlin 2.2.20, you can now compile `when` expressions with `invokedynamic`. Previously, `when` expressions with multiple type checks compiled to a long chain of `instanceof` checks in the bytecode.

Now you can use `invokedynamic` with `when` expressions to generate smaller bytecode, similar to the bytecode produced by Java `switch` statements, when the following conditions are met:

- All conditions except for `else` are `is` or `null` checks.
- The expression doesn't contain guard conditions (`if`).
- The conditions don't include types that can't be type-checked directly, such as mutable Kotlin collections (`MutableList`) or function types (`kotlin.Function1` , `kotlin.Function2` , and so on).
- There are at least two conditions besides `else` .
- All branches check the same subject of the `when` expression.

For example:

```
open class Example

class A : Example()
class B : Example()
class C : Example()

fun test(e: Example) = when (e) {
    // Uses invokedynamic with SwitchBootstraps.typeSwitch
    is A → 1
    is B → 2
    is C → 3
    else → 0
}
```

With the new feature enabled, the `when` expression in this example compiles to a single `invokedynamic` type switch instead of multiple `instanceof` checks.

To enable this feature, compile your Kotlin code with JVM target 21 or above and add the following compiler option:

```
-Xwhen-expressions=indy
```

Or add it to the `compilerOptions {}` block of your `build.gradle(.kts)` file:

```
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xwhen-expressions=indy")
    }
}
```

This feature is Experimental. We would appreciate your feedback in our issue tracker, YouTrack.

Kotlin Multiplatform

Kotlin 2.2.20 introduces significant changes for Kotlin Multiplatform: Swift export is available by default, there's a new shared source set, and you can try a new approach to managing common dependencies.

Experimental

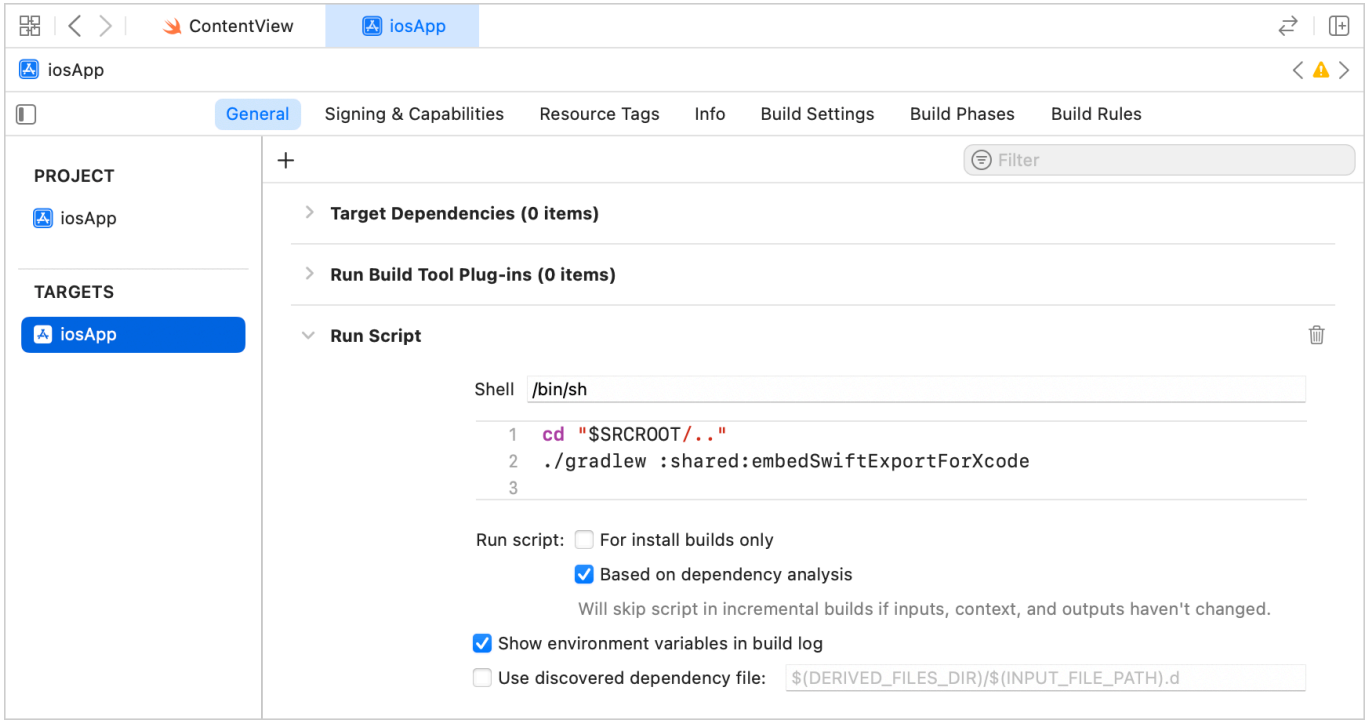
Swift export available by default

Kotlin 2.2.20 introduces experimental support for Swift export. It allows you to export Kotlin sources directly and call Kotlin code from Swift idiomatically, eliminating the need for Objective-C headers.

This should significantly improve multiplatform development for Apple targets. For example, if you have a Kotlin module with top-level functions, Swift export enables clean, module-specific imports, removing the confusing Objective-C underscores and mangled names.

The key features are:

- **Multi-module support**. Each Kotlin module is exported as a separate Swift module, simplifying function calls.
- **Package support**. Kotlin packages are explicitly preserved during export, avoiding naming conflicts in the generated Swift code.
- **Type aliases**. Kotlin type aliases are exported and preserved in Swift, improving readability.
- **Enhanced nullability for primitives**. Unlike Objective-C interop, which required boxing types like `Int?` into wrapper classes like `KotlinInt` to preserve nullability, Swift export converts nullability information directly.
- **Overloads**. You can call Kotlin's overloaded functions in Swift without ambiguity.
- **Flattened package structure**. You can translate Kotlin packages into Swift enums, removing the package prefix from generated Swift code.
- **Module name customization**. You can customize the resulting Swift module names in the Gradle configuration of your Kotlin project.



How to enable Swift export

The feature is currently Experimental and works only in projects that use direct integration to connect the iOS framework to the Xcode project. This is a standard configuration for multiplatform projects created with the Kotlin Multiplatform plugin in IntelliJ IDEA or through the web wizard.

To try out Swift export, configure your Xcode project:

1. In Xcode, open the project settings.
2. On the **Build Phases** tab, locate the **Run Script** phase with the `embedAndSignAppleFrameworkForXcode` task.
3. Adjust the script to feature the `embedSwiftExportForXcode` task instead in the run script phase:

```
./gradlew :<Shared module name>:embedSwiftExportForXcode
```

Add the Swift export script

4. Build the project. Swift modules are generated in the build output directory.

The feature is available by default. If you have already enabled it in previous releases, you can now remove `kotlin.experimental.swift-export.enabled` from your `gradle.properties` file.

> To save time, clone our public sample with Swift export already set up.

For more information about Swift export, see our documentation.

Leave feedback

We're planning to expand and gradually stabilize Swift export support in future Kotlin releases. After Kotlin 2.2.20, we'll focus on improving interoperability between Kotlin and Swift, particularly around coroutines and flows.

Support for Swift export is a significant change for Kotlin Multiplatform. We would appreciate your feedback:

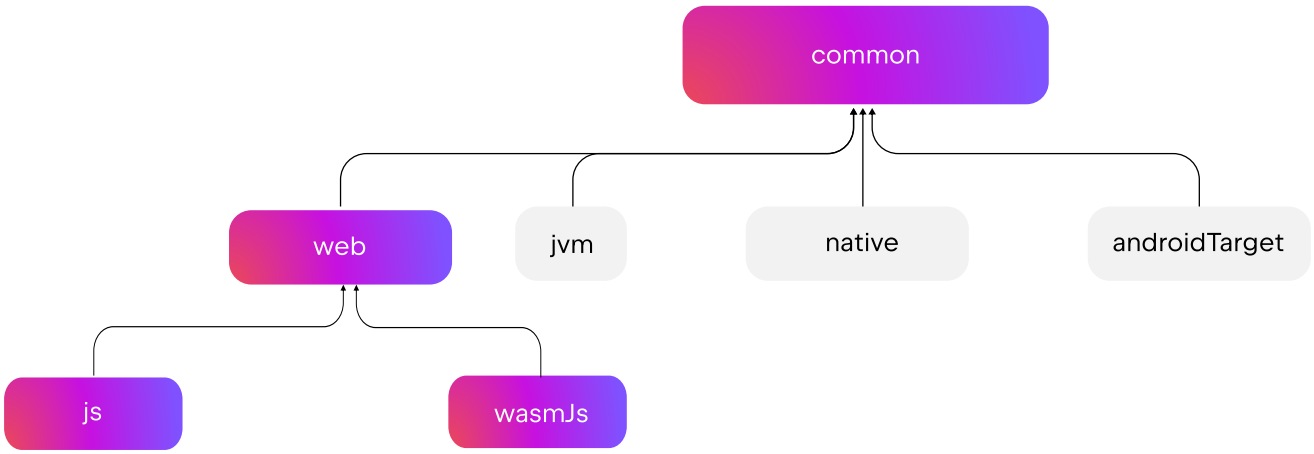
- Contact the development team directly in Kotlin Slack – get an invite and join the #swift-export channel.
- Report any problems you face with Swift export in YouTrack.

Shared source set for `js` and `wasmJs` targets

Previously, Kotlin Multiplatform didn't include a shared source set for JavaScript (`js`) and WebAssembly (`wasmJs`) web targets by default. To share code between `js` and `wasmJs` , you had to manually configure a custom source set or write code in two places, one version for `js` and another for `wasmJs` . For example:

```
// commonMain
expect suspend fun readCopiedText(): String

// jsMain
external interface Navigator { val clipboard: Clipboard }
// Different interop in JS and Wasm
external interface Clipboard { fun readText(): Promise<String> }
external val navigator: Navigator



suspend fun readCopiedText(): String {
    // Different interop in JS and Wasm
    return navigator.clipboard.readText().await()
}

// wasmJsMain
external interface Navigator { val clipboard: Clipboard }
external interface Clipboard { fun readText(): Promise<JsString> }
external val navigator: Navigator

suspend fun readCopiedText(): String {
    return navigator.clipboard.readText().await().toString()
}
```

Starting with this release, the Kotlin Gradle plugin adds a new shared source set for web (comprising `webMain` and `webTest`) when you use the default hierarchy template.

With this change, the `web` source set becomes a parent of both `js` and `wasmJs` source sets. The updated source set hierarchy looks like this:

An example of using the default hierarchy template with web

The new source set allows you to write one piece of code for both the `js` and `wasmJs` targets. You can put your shared code in `webMain` and have it automatically work for both:

```
// commonMain
expect suspend fun readCopiedText(): String

// webMain
@OptIn(ExperimentalWasmJsInterop::class)
private suspend fun <R : JsAny?> Promise<R>.await(): R = suspendCancellableCoroutine { continuation ->
    this.then(
        onFulfilled = { continuation.resumeWith(Result.success(it)); null },
        onRejected = { continuation.resumeWithException(it.asJsException()); null }
    )
}

external interface Navigator { val clipboard: Clipboard }
external interface Clipboard { fun readText(): Promise<JsString> }
external val navigator: Navigator

actual suspend fun readCopiedText(): String {
    return navigator.clipboard.readText().await().toString()
}
```

This update simplifies code sharing between the `js` and `wasmJs` targets. It is particularly useful in two cases:

- If you're a library author, and you want to add support for both the `js` and `wasmJs` targets, without duplicating code.
- If you're developing Compose Multiplatform applications that target the web, enabling cross-compilation for both the `js` and `wasmJs` targets for wider browser compatibility. Given this fallback mode, when you create a website, it works on all browsers out of the box, as modern browsers use `wasmJs` and older ones use `js`.

To try this feature, use the default hierarchy template in the `kotlin {}` block of your `build.gradle(.kts)` file:

```
kotlin {
    js()
    wasmJs()

    // Enables the default source set hierarchy, including webMain and webTest
    applyDefaultHierarchyTemplate()
}
```

Before using the default hierarchy, consider carefully any potential conflicts if you have projects with a custom shared source set or if you've renamed the `js("web")` target. To resolve these conflicts, rename the conflicting source set or target, or don't use the default hierarchy.

Stable cross-platform compilation for Kotlin libraries

Kotlin 2.2.20 completes an important roadmap item, stabilizing cross-platform compilation for Kotlin libraries.

You can now use any supported host to produce `.klib` artifacts for publishing Kotlin libraries. This significantly streamlines the publishing process, particularly for Apple targets that previously required a Mac machine.

The feature is available by default. If you have already enabled cross-compilation with `kotlin.native.enableKlibsCrossCompilation=true`, you can now remove it from your `gradle.properties` file.

Unfortunately, a few limitations are still present. You still need to use a Mac machine if:

- Your library or any dependent modules have cinterop dependencies.
- You have the CocoaPods integration set up in your project.

- You need to build or test final binaries for Apple targets.

For more information about the publication of multiplatform libraries, see our documentation.

Experimental

New approach for declaring common dependencies

To simplify setting up multiplatform projects with Gradle, Kotlin 2.2.20 now lets you declare common dependencies in the `kotlin {}` block by using a top-level `dependencies {}` block when your project uses Gradle 8.8 or higher. These dependencies behave as if they were declared in the `commonMain` source set. This feature works similarly to the dependencies block that you use for Kotlin/JVM and Android-only projects, and it's now Experimental in Kotlin Multiplatform.

Declaring common dependencies at the project level reduces repetitive configuration across source sets and helps streamline your build setup. You can still add platform-specific dependencies in each source set as needed.

To try this feature, opt in by adding the `@OptIn(ExperimentalKotlinGradlePluginApi::class)` annotation before the top-level `dependencies {}` block. For example:

```
kotlin {
    @OptIn(ExperimentalKotlinGradlePluginApi::class)
    dependencies {
        implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
    }
}
```

We would appreciate your feedback on this feature in YouTrack.

New diagnostic for target support in dependencies

Before Kotlin 2.2.20, if a dependency in your build script didn't support all the targets required by the source set, the error messages produced by Gradle made it hard to understand the problem.

Kotlin 2.2.20 introduces a new diagnostic that clearly shows which targets each dependency supports and which it doesn't.

This diagnostic is enabled by default. If, for some reason, you need to disable it, let us know in a comment in this YouTrack issue. You can use the following Gradle properties to disable the diagnostic in your `gradle.properties` file:

Property	Description
`kotlin.kmp.eagerUnresolvedDependenciesDiagnostic=false`	Runs the diagnostic only for metadata compilations and imports
`kotlin.kmp.unresolvedDependenciesDiagnostic=false`	Disables the diagnostic completely

Kotlin/Native

This release brings support for Xcode 26, improvements to interoperability with Objective-C/Swift, debugging, and new binary options.

Support for Xcode 26

Starting with Kotlin 2.2.21, the Kotlin/Native compiler supports Xcode 26 – the latest stable version of Xcode. You can now update your Xcode and get access to the latest APIs to continue working on your Kotlin projects for Apple operating systems.

Support for stack canaries in binaries

Starting with Kotlin 2.2.20, Kotlin adds support for stack canaries in the resulting Kotlin/Native binaries. As part of stack protection, this security feature protects against stack smashing, mitigating some common application vulnerabilities. Already available in Swift and Objective-C, it's now supported in Kotlin as well.

The implementation of stack protection in Kotlin/Native follows the behavior of the stack protector in Clang.

To enable stack canaries, add the following binary option to your `gradle.properties` file:

```
kotlin.native.binary.stackProtector=yes
```

The property enables the feature for all the Kotlin functions that are vulnerable to stack smashing. Alternative modes are:

- `kotlin.native.binary.stackProtector=strong`, which uses a stronger heuristic for the functions vulnerable to stack smashing.
- `kotlin.native.binary.stackProtector=all`, which enables stack protectors for all functions.

Note that in some cases, stack protection might come with a performance cost.

Experimental

Smaller binary size for release binaries

Kotlin 2.2.20 introduces the `smallBinary` option that can help you decrease the binary size for release binaries. The new option effectively sets `-Oz` as the default optimization argument for the compiler during the LLVM compilation phase.

With the `smallBinary` option enabled, you can make release binaries smaller and improve build time. However, it might affect runtime performance in some cases.

The new feature is currently Experimental. To try it out in your project, add the following binary option to your `gradle.properties` file:

```
kotlin.native.binary.smallBinary=true
```

The Kotlin team is grateful to Troels Lund for his help in implementing this feature.

Improved debugger object summaries

Kotlin/Native now generates clearer object summaries for debugger tools like LLDB and GDB. This improves the readability of the produced debug information and streamlines your debugging experience.

Consider the following object, for example:

```
class Point(val x: Int, val y: Int)
val point = Point(1, 2)
```

Previously, the inspection would show you only limited information, including a pointer to the object's memory address:

```
(lldb) v point
(ObjHeader *) point = [x: ..., y: ...]
(lldb) v point→x
(int32_t *) x = 0x0000000100274048
```

With Kotlin 2.2.20, the debugger now shows richer details, including the actual values:

```
(lldb) v point
(ObjHeader *) point = Point(x=1, y=2)
(lldb) v point→x
(int32_t) point→x = 1
```

The Kotlin team is grateful to Nikita Nazarov for his help in implementing this feature.

For more information on debugging in Kotlin/Native, see the documentation.

Explicit names in block types for Objective-C headers

Kotlin 2.2.20 introduces an option to add explicit parameter names to Kotlin's function types for Objective-C headers exported from Kotlin/Native projects. Parameter names improve autocomplete suggestions in Xcode and help avoid Clang warnings.

Previously, parameter names in block types were omitted in the generated Objective-C headers. In such cases, Xcode's autocompletion would suggest calling such functions without parameter names in the Objective-C block. The generated block would trigger Clang warnings.

For example, for the following Kotlin code:

```
// Kotlin:
fun greetUser(block: (name: String) → Unit) = block("John")
```

The generated Objective-C header had no parameter name:

```
// Objective-C:
+ (void)greetUserBlock:(void (^)(NSString *))block __attribute__((swift_name("greetUser(block:)")));
```

So when calling the `greetUserBlock()` function from Objective-C in Xcode, the IDE suggested:

```
// Objective-C:
greetUserBlock:^(NSString *) {
    // ...
};
```

The missing parameter name `(NSString *)` in the suggestion caused Clang warnings.

With the new option, Kotlin forwards the parameter names from Kotlin function types to Objective-C block types, so Xcode uses them in suggestions:

```
// Objective-C:
greetUserBlock:^(NSString *name) {
    // ...
};
```

To enable explicit parameter names, add the following binary option to your `gradle.properties` file:

```
kotlin.native.binary.objcExportBlockExplicitParameterNames=true
```

The Kotlin team is grateful to Yijie Jiang for implementing this feature.

Reduced size of Kotlin/Native distribution

The Kotlin/Native distribution used to contain two JAR files with compiler code:

- `konan/lib/kotlin-native.jar`
- `konan/lib/kotlin-native-compiler-embeddable.jar`.

Starting with Kotlin 2.2.20, `kotlin-native.jar` is no longer published.

The removed JAR file is the legacy version of the embeddable compiler, which is no longer needed. This change significantly reduces the size of the distribution.

As a consequence, the following options are now deprecated and removed:

- The `kotlin.native.useEmbeddableCompilerJar=false` Gradle property. Instead, the embeddable compiler JAR file is always used for Kotlin/Native projects.
- The `KotlinCompilerPluginSupportPlugin.getPluginArtifactForNative()` function. Instead, the `getPluginArtifact()` function is always used.

For more information, see the YouTrack issue.

Exporting KDocs to Objective-C headers by default

KDoc comments are now exported by default when generating Objective-C headers during compilation of Kotlin/Native final binaries.

Previously, you needed to add the `-Xexport-kdoc` option manually to your build file. Now, it's automatically passed to compilation tasks.

This option embeds KDoc comments into klibs and extracts comments from klibs when producing Apple frameworks. As a result, comments on classes and methods appear during autocompletion, for example, in Xcode.

You can disable the export of KDoc comments from klibs to the produced Apple frameworks in the `binaries {}` block of your `build.gradle(.kts)` file:

```
import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

kotlin {
    iosArm64 {
        binaries {
            framework {
                baseName = "sdk"
                @OptIn(ExperimentalKotlinGradlePluginApi::class)
                exportKdoc.set(false)
            }
        }
    }
}
```

For more information, see our documentation.

Deprecation of `x86_64` Apple targets

Apple stopped producing devices with Intel chips a couple of years ago and recently announced that macOS Tahoe 26 will be the last OS version to support Intel-based architecture.

This makes it increasingly difficult for us to properly test these targets on our build agents, especially in future Kotlin releases where we'll update the supported Xcode version that comes with macOS 26.

Starting with Kotlin 2.2.20, the `macosX64` and `iosX64` targets are demoted to support tier 2. This means the target is regularly tested on CI to ensure it compiles, but it might not be automatically tested to ensure it runs.

We plan to gradually deprecate all `x86_64` Apple targets and eventually remove support for them during the Kotlin 2.2.20-2.4.0 release cycle. This includes the following targets:

- `macosX64`
- `iosX64`
- `tvosX64`
- `watchosX64`

For more information on support tiers, see Kotlin/Native target support.

Kotlin/Wasm

Kotlin/Wasm is now Beta, offering greater stability along with improvements such as separated npm dependencies, refined exception handling for JavaScript interop, built-in browser debugging support, and more.

Separated npm dependencies

Previously, in your Kotlin/Wasm projects, all npm dependencies were installed together in your project folder, including both Kotlin tooling dependencies and your own. They were also recorded together in your project's lock files (`package-lock.json` or `yarn.lock`).

As a result, whenever Kotlin tooling dependencies were updated, you had to update your lock files even if you didn't add or change anything.

Starting from Kotlin 2.2.20, the Kotlin tooling npm dependencies are installed outside your project. Now, the tooling and your (user) dependencies have separate directories:

- **Tooling dependencies' directory:**

  `<kotlin-user-home>/kotlin-npm-tooling/<yarn|npm>/hash/node_modules`

- **User dependencies' directory:**

  `build/wasm/node_modules`

In addition, the lock files inside the project directory contain only user-defined dependencies.

This improvement keeps your lock files focused only on your own dependencies, helps maintain a cleaner project, and reduces unnecessary changes to your files.

This change is enabled by default for the `wasm-js` target. The change is not yet implemented for the `js` target. While there are plans to implement it in future releases, the behavior of the npm dependencies remains the same as before for the `js` target in Kotlin 2.2.20.

Improved exception handling in Kotlin/Wasm and JavaScript interop

Previously, Kotlin had difficulty understanding exceptions (errors) thrown in JavaScript (JS) and crossing over to Kotlin/Wasm code.

In some cases, the issue also occurred in the reverse direction, when an exception was thrown or passed through the Wasm code to JS and wrapped into `WebAssembly.Exception` without any details. These Kotlin exception handling issues made debugging difficult.

Starting from Kotlin 2.2.20, the developer experience with exceptions improves in both directions:

- When exceptions are thrown from JS, you can see more information on Kotlin's side. When such an exception propagates through Kotlin back to JS, it's no longer wrapped into WebAssembly.
- When exceptions are thrown from Kotlin, they can now be caught on the JS side as JS errors.

The new exception handling works automatically in modern browsers that support the `WebAssembly.JSTag` feature:

- Chrome 115+
- Firefox 129+
- Safari 18.4+

In older browsers, the exception handling behavior remains unchanged.

Support for debugging in browsers without configuration

Previously, browsers couldn't automatically access the Kotlin/Wasm project sources required for debugging. To debug Kotlin/Wasm applications in the browser, you had to manually configure your build to serve these sources by adding the following snippet to your `build.gradle(.kts)` file:

```
devServer = (devServer ?: KotlinWebpackConfig.DevServer()).apply {
    static = (static ?: mutableListOf()).apply {
        add(project.rootDir.path)
    }
}
```

Starting with Kotlin 2.2.20, debugging your applications in modern browsers works out of the box. When you run Gradle development tasks (`*DevRun`), Kotlin automatically serves the source files to the browser, allowing you to set breakpoints, inspect variables, and step through Kotlin code without extra setup.

This change simplifies debugging by removing the need for manual configuration. The required configuration is now included in the Kotlin Gradle plugin. If you previously added this configuration to your `build.gradle(.kts)` file, you should remove it to avoid conflicts.

Debugging in browsers is enabled by default for all Gradle `*DevRun` tasks. These tasks serve not only the application but also its source files, so use them only for local development and avoid running them in cloud or production environments where the sources would be publicly exposed.

Handle repeated reloads during debugging

Serving sources by default may cause repeated reloads of the application in the browser before Kotlin compilation and bundling are complete. As a workaround, adjust your webpack configuration to ignore Kotlin source files and disable watching for served static files. Add a `.js` file with the following content into the `webpack.config.d` directory at the root of your project:

```
config.watchOptions = config.watchOptions || {
    ignored: ["**/*.kt", "**/node_modules"]
}

if (config.devServer) {
    config.devServer.static = config.devServer.static.map(file => {
        if (typeof file === "string") {
        return { directory: file,
                 watch: false,
        }
    } else {
        return file
    }
    })
}
```

Elimination of empty `yarn.lock` files

Previously, the Kotlin Gradle plugin (KGP) automatically generated a `yarn.lock` file that included information about npm packages required by the Kotlin toolchain, along with any existing npm dependencies from the project or used libraries.

Now, the KGP manages toolchain dependencies separately, and a project-level `yarn.lock` file is no longer generated unless the project has npm dependencies.

The KGP automatically creates a `yarn.lock` file when npm dependencies are added, and it deletes the `yarn.lock` file when npm dependencies are removed.

This change cleans up project structures and makes it easier to track when actual npm dependencies are introduced.

No additional steps are required to configure this behavior. It's applied by default in Kotlin/Wasm projects starting from Kotlin 2.2.20.

New compiler error in fully qualified class names

On Kotlin/Wasm, the compiler doesn't store fully qualified names (FQNs) of classes in the generated binary by default. This approach avoids increasing the application size.

As a result, in previous Kotlin releases, calling the `KClass::qualifiedName` property returned an empty string instead of the class's qualified name.

Starting with Kotlin 2.2.20, the compiler reports an error when you use the `KClass::qualifiedName` property in Kotlin/Wasm projects, unless you explicitly enable the qualified names feature.

This change prevents unexpected empty strings when calling the `qualifiedName` property and improves developer experience by catching issues at compile time.

The diagnostic is enabled by default, and errors are reported automatically. To disable the diagnostics and allow storing FQNs in Kotlin/Wasm, instruct the compiler to store fully qualified names for all classes by adding the following option to your `build.gradle(.kts)` file:

```
kotlin {
    wasmJs {
        ...
        compilerOptions {
            freeCompilerArgs.add("-Xwasm-kclass-fqn")
        }
    }
}
```

Keep in mind that enabling this option increases the application size.

Kotlin/JS

Kotlin 2.2.20 supports using the `BigInt` type to represent Kotlin's `Long` type, enabling `Long` in exported declarations. Additionally, this release adds a DSL function to clean up Node.js arguments.

Experimental

Usage of the `BigInt` type to represent Kotlin's `Long` type

Before the ES2020 standard, JavaScript (JS) did not support a primitive type for precise integers larger than 53 bits.

For this reason, Kotlin/JS used to represent `Long` values (which are 64-bit wide) as JavaScript objects containing two `number` properties. This custom implementation made interoperability between Kotlin and JavaScript more complex.

Starting with Kotlin 2.2.20, Kotlin/JS now uses JavaScript's built-in `BigInt` type to represent Kotlin's `Long` values when compiling to modern JavaScript (ES2020).

This change enables exporting the `Long` type to JavaScript, a feature also introduced in Kotlin 2.2.20. As a result, this change simplifies the interoperability between Kotlin and JavaScript.

To enable it, you need to add the following compiler option to your `build.gradle(.kts)` file:

```
kotlin {
    js {
        ...
        compilerOptions {
            freeCompilerArgs.add("-Xes-long-as-bigint")
        }
    }
}
```

This feature is Experimental. We would appreciate your feedback in our issue tracker, YouTrack.

Usage of `Long` in exported declarations

Because Kotlin/JS used a custom `Long` representation, it was difficult to provide a straightforward way to interact with Kotlin's `Long` from JavaScript. As a result, you couldn't export Kotlin code that used the `Long` type to JavaScript. This issue affected any code using `Long`, such as function parameters, class properties, or constructors.

Now that Kotlin's `Long` type can be compiled to JavaScript's `BigInt` type, Kotlin/JS supports exporting `Long` values to JavaScript, simplifying the interoperability between Kotlin and JavaScript code.

To enable this feature:

1. Allow exporting `Long` in Kotlin/JS by adding the following compiler option to the `freeCompilerArgs` attribute in your `build.gradle(.kts)` file:

```
kotlin {
    js {
        ...
        compilerOptions {
            freeCompilerArgs.add("-XXLanguage:+JsAllowLongInExportedDeclarations")
        }
    }
}
```

2. Enable the `BigInt` type. See how to enable it in Usage of the `BigInt` type to represent Kotlin's `Long` type.

New DSL function for cleaner arguments

When running a Kotlin/JS application with Node.js, the arguments passed to your program (`args`) used to include:

- The path to the executable `Node` .
- The path to your script.
- The actual command-line arguments you provided.

However, the expected behavior for `args` was to include only the command-line arguments. To achieve this, you had to manually skip the first two arguments using the `drop()` function inside your `build.gradle(.kts)` file or in your Kotlin code:

```
fun main(args: Array<String>) {
    println(args.drop(2).joinToString(", "))
}
```

This workaround was repetitive, error-prone, and didn't work well when sharing code between platforms.

To fix this issue, Kotlin 2.2.20 introduces a new DSL function called `passCliArgumentsToMainFunction()` .

With this function, only the command-line arguments are included, while the `Node` and script paths are excluded:

```
fun main(args: Array<String>) {
    // No need for drop() and only your custom arguments are included
    println(args.joinToString(", "))
}
```

This change reduces boilerplate code, prevents mistakes caused by manually dropping arguments, and improves cross-platform compatibility.

To enable this feature, add the following DSL function inside your `build.gradle(.kts)` file:

```
kotlin {
    js {
        nodejs {
            passCliArgumentsToMainFunction()
        }
    }
}
```

Gradle

Kotlin 2.2.20 adds new compiler performance metrics for Kotlin/Native tasks in Gradle build reports and makes quality-of-life improvements in incremental compilation.

New compiler performance metrics in build reports for Kotlin/Native tasks

In Kotlin 1.7.0, we introduced build reports to help track compiler performance. Since then, we've added more metrics to make these reports even more detailed and useful for investigating performance issues.

In Kotlin 2.2.20, build reports now include compiler performance metrics for Kotlin/Native tasks.

To learn more about build reports and how to configure them, see Enabling build reports.

Experimental

Preview improved incremental compilation for Kotlin/JVM

Kotlin 2.0.0 introduced the new K2 compiler with an optimized frontend. Kotlin 2.2.20 builds on this by using the new frontend to improve performance in certain complex incremental compilation scenarios for Kotlin/JVM.

These improvements are disabled by default while we work on stabilizing the behavior. To enable them, add the following property in your `gradle.properties` file:

```
kotlin.incremental.jvm.fir=true
```

Currently, the `kapt` compiler plugin isn't compatible with this new behavior. We're working on adding support in a future Kotlin release.

We'd appreciate your feedback on this feature in YouTrack.

Incremental compilation detects changes in lambdas of inline functions

Before Kotlin 2.2.20, if you enabled incremental compilation and changed the logic inside a lambda in an inline function, the compiler didn't recompile the call sites of that inline function in other modules. As a result, those call sites used the previous version of the lambda, which could cause unexpected behavior.

In Kotlin 2.2.20, the compiler now detects changes in lambdas of inline functions and automatically recompiles their call sites.

Improvements for library publication

Kotlin 2.2.20 adds new Gradle tasks that make library publication easier. These tasks help you generate key pairs, upload public keys, and run local checks to ensure the verification process succeeds before uploading to the Maven Central repository.

For more information about how to use these tasks as part of the publication process, see Publish your library to Maven Central.

New Gradle tasks for generating and uploading PGP keys

Before Kotlin 2.2.20, if you wanted to publish a multiplatform library to the Maven Central repository, you had to install a third-party program like `gpg` to generate a key pair for signing your publications. Now, the Kotlin Gradle plugin comes with Gradle tasks that let you generate a key pair and upload the public key so you don't have to install another program.

Generate a key pair

The `generatePgpKeys` task generates a key pair. When you run it, you must provide a password for the private keystore and your name in the following format:

```
./gradlew -Psigning.password=example-password generatePgpKeys --name "John Smith <john@example.com>"
```

The task stores the key pair in the `build/pgp` directory.

> Move your key pair to a secure location to prevent accidental deletion or unauthorized access.

Upload the public key

The `uploadPublicPgpKey` task uploads the public key to Ubuntu's key server: `keyserver.ubuntu.com`. When you run it, provide the path to the public key in `.asc` format:

```
./gradlew uploadPublicPgpKey --keyring /path_to/build/pgp/public_KEY_ID.asc
```

New Gradle tasks to test verification locally

Kotlin 2.2.20 also adds Gradle tasks for testing verification locally before uploading your library to the Maven Central repository.

If you're using the Kotlin Gradle plugin along with Gradle's Signing Plugin and Maven Publish Plugin, you can run the `checkSigningConfiguration` and `checkPomFileFor<PUBLICATION_NAME>Publication` tasks to verify that your setup meets Maven Central's requirements. Replace `<PUBLICATION_NAME>` with the name of your publication.

These tasks aren't automatically run as part of the `build` or `check` Gradle tasks, so you need to run them manually. For example, if you have a `KotlinMultiplatform` publication:

```
./gradlew checkSigningConfiguration checkPomFileForKotlinMultiplatformPublication
```

The `checkSigningConfiguration` task checks that:

- The Signing Plugin has keys configured.
- The configured public key has been uploaded to either `keyserver.ubuntu.com` or `keys.openpgp.org` key servers.
- All publications have signing enabled.

If any of these checks fail, the task returns an error with information on how to fix the issue.

The `checkPomFileFor<PUBLICATION_NAME>Publication` task checks whether the `pom.xml` file meets Maven Central's requirements. If it doesn't, the task returns an error with details about which parts of the `pom.xml` file are non-compliant.

Maven: Support for the Kotlin daemon in the `kotlin-maven-plugin`

Kotlin 2.2.20 takes the build tools API introduced in Kotlin 2.2.0 one step further by adding support for the Kotlin daemon in the `kotlin-maven-plugin`. When using the Kotlin daemon, the Kotlin compiler runs in a separate isolated process, which prevents other Maven plugins from overriding system properties. You can see an example in this YouTrack issue.

Starting with Kotlin 2.2.20, the Kotlin daemon is used by default. If you want to revert to the previous behavior, opt out by setting the following property in your `pom.xml` file to `false`:

```
<properties>
    <kotlin.compiler.daemon>false</kotlin.compiler.daemon>
</properties>
```

Kotlin 2.2.20 also introduces a new `jvmArgs` property, which you can use to customize the default JVM arguments for the Kotlin daemon. For example, to override the `-Xmx` and `-Xms` options, add the following to your `pom.xml` file:

```
<properties>
    <kotlin.compiler.daemon.jvmArgs>Xmx1500m,Xms500m</kotlin.compiler.daemon.jvmArgs>
</properties>
```

New common schema for Kotlin compiler options

Kotlin 2.2.20 introduces a common schema for all compiler options published under `org.jetbrains.kotlin:kotlin-compiler-arguments-description`. This artifact includes both a code representation and a JSON equivalent (for non-JVM consumers) of all compiler options, their descriptions, and metadata such as the version in which each option was introduced or stabilized. You can use this schema to generate a custom view of the options or analyze them as needed.

Standard library

This release introduces new experimental features in the standard library: reflection support for identifying interface types in Kotlin/JS, update functions for common atomic types, and `copyOf()` overloads for array resizing.

Experimental

Support for identifying interface types through reflection in Kotlin/JS

Kotlin 2.2.20 adds the Experimental `KClass.isInterface` property to the Kotlin/JS standard library.

With this property, you can now check whether a class reference represents a Kotlin interface. This brings Kotlin/JS closer to parity with Kotlin/JVM, where you can use `KClass.java.isInterface` to check if a class represents an interface.

To opt in, use the `@OptIn(ExperimentalStdlibApi::class)` annotation:

```
@OptIn(ExperimentalStdlibApi::class)
fun inspect(klass: KClass<*>) {
    // Prints true for interfaces
    println(klass.isInterface)
}
```

We would appreciate your feedback in our issue tracker, YouTrack.

Experimental

New update functions for common atomic types

Kotlin 2.2.20 introduces new experimental functions for updating common atomic types and elements of their array counterparts. Each function atomically computes a new value using one of these update functions and replaces the current value, with the return value depending on which function you use:

- `update()` and `updateAt()` set a new value without returning a result.
- `fetchAndUpdate()` and `fetchAndUpdateAt()` set a new value and return the previous value before the change.
- `updateAndFetch()` and `updateAndFetchAt()` set a new value and return the updated value after the change.

You can use these functions to implement atomic transformations that aren't supported out of the box, such as multiplication or bitwise operations. Before this change, incrementing a common atomic type and reading the previous value required a loop with the `compareAndSet()` function.

Like all APIs for common atomic types, these functions are Experimental. To opt in, use the `@OptIn(ExperimentalAtomicApi::class)` annotation.

Here's an example of code that performs different kinds of updates and returns either the previous or updated value:

```
import kotlin.concurrent.atomics.*
import kotlin.random.Random

@OptIn(ExperimentalAtomicApi::class)
fun main() {
    val counter = AtomicLong(Random.nextLong())
    val minSetBitsThreshold = 20

    // Sets a new value without using the result
    counter.update { if (it < 0xDECAF) 0xCACA0 else 0xC0FFEE }

    // Retrieves the current value, then updates it
    val previousValue = counter.fetchAndUpdate { 0x1CEDL.shl(Long.SIZE_BITS -
it.countLeadingZeroBits()) or it }

    // Updates the value, then retrieves the result
    val current = counter.updateAndFetch {
        if (it.countOneBits() < minSetBitsThreshold) it.shl(20) or 0x15BADL else it
    }

    val hexFormat = HexFormat {
        upperCase = true
        number {
            removeLeadingZeros = true
        }
    }
    println("Previous value: ${previousValue.toHexString(hexFormat)}")
    println("Current value: ${current.toHexString(hexFormat)}")
    println("Expected status flag set: ${current and 0xBAD == 0xBADL}")
}
```

We would appreciate your feedback in our issue tracker, YouTrack.

Experimental

Support for `copyOf()` overloads for arrays

Kotlin 2.2.20 introduces an experimental overload for the `copyOf()` function. It's available for arrays of generic type `Array<T>` and all primitive array types.

You can use this function to make an array larger and populate the new elements using values from an initializer lambda. This can help you reduce custom boilerplate code and fixes the common pain point where resizing a generic `Array<T>` produced a nullable result (`Array<T?>`).

Here's an example:

```
@OptIn(ExperimentalStdlibApi::class)
fun main() {
    val row1: Array<String> = arrayOf("one", "two")
    // Resizes the array and populates the new elements using the lambda
    val row2: Array<String> = row1.copyOf(4) { "default" }
    println(row2.contentToString())
    // [one, two, default, default]
}
```

This API is Experimental. To opt in, use the `@OptIn(ExperimentalStdlibApi::class)` annotation.

We would appreciate your feedback in our issue tracker.

Compose compiler

In this release, the Compose compiler brings quality-of-life improvements by adding new warnings and improving the output of build metrics to make them easier to read.

Language version restrictions for default parameters

With this release, the Compose compiler reports an error if the language version specified for compilation is lower than what's required to support default parameters in abstract or open composable functions.

Default parameters are supported in the Compose compiler, starting with Kotlin 2.1.0 for abstract functions and Kotlin 2.2.0 for open functions. When using a newer version of the Compose compiler while targeting older Kotlin language versions, library developers should be aware that default parameters in abstract or open functions may still appear in the public API, even if the language version doesn't support them.

Composable target warnings for the K2 compiler

This release adds warnings about `@ComposableTarget` mismatches when using the K2 compiler.

For example:

```
@Composable fun App() {
  Box { // <-- `Box` is a `@UiComposable`
    Path(...) // <-- `Path` is a `@VectorComposable`
    ^^^^^^^^^
    warning: Calling a Vector composable function where a UI composable was expected
  }
}
```

Fully qualified names in build metrics

Class and function names reported in build metrics are now fully qualified, making it easier to distinguish between declarations with the same name in different packages.

In addition, build metrics no longer include a dump of complex expressions from default parameters, making them easier to read.

Breaking changes and deprecations

This section highlights important breaking changes and deprecations worth noting:

- The kapt compiler plugin now uses the K2 compiler by default. As a result, the `kapt.use.k2` property, which controls whether the plugin uses the K2 compiler, is deprecated. If you set this property to `false` to opt out of using the K2 compiler, Gradle shows a warning.

Documentation updates

The Kotlin documentation has received some notable changes:

- Kotlin roadmap – See the updated list of Kotlin's priorities on language and ecosystem evolution.
- Properties – Learn about the many ways that you can use properties in Kotlin.
- Conditions and loops – Learn how conditions and loops work in Kotlin.

- Kotlin/JavaScript – Explore the use cases for Kotlin/JS.
- Targeting the web – Learn about the different targets that Gradle offers for web development.
- Kotlin daemon – Learn about the Kotlin daemon and how it works with build systems and the Kotlin compiler.
- Coroutines overview page – Learn about coroutine concepts and get started on your learning journey.
- Kotlin/Native binary options – Learn about the binary options for Kotlin/Native and how to configure them.
- Debugging Kotlin/Native – Explore the different ways that you can debug with Kotlin/Native.
- Tips for customizing LLVM backend – Learn how Kotlin/Native uses LLVM and adjust optimization passes.
- Get started with Exposed's DAO API – Learn how to use Exposed's Data Access Object (DAO) API to store and retrieve data in a relational database.
- New pages in Exposed documentation about R2DBC:
  - Working with databases
  - Working with ConnectionFactory
  - Custom type mapping
- HTMX integration – Learn how Ktor provides experimental, first-class support for HTMX.

How to update to Kotlin 2.2.20

The Kotlin plugin is distributed as a bundled plugin in IntelliJ IDEA and Android Studio.

To update to the new Kotlin version, change the Kotlin version to 2.2.20 in your build scripts.

What's new in Kotlin 2.2.0

Released: June 23, 2025

The Kotlin 2.2.0 release is here! Here are the main highlights:

- **Language**: new language features in preview, including context parameters. Several previously experimental features are now Stable, such as guard conditions, non-local break and continue, and multi-dollar interpolation.
- **Kotlin compiler**: Unified management of compiler warnings.
- **Kotlin/JVM**: Changes to default method generation for interface functions.
- **Kotlin/Native**: LLVM 19 and new features for tracking and adjusting memory consumption.
- **Kotlin/Wasm**: Separated Wasm target and the ability to configure Binaryen per project.
- **Kotlin/JS**: Fix for the `copy()` method generated for `@JsPlainObject` interfaces.
- **Gradle**: Binary compatibility validation in the Kotlin Gradle plugin.
- **Standard library**: Stable Base64 and HexFormat APIs.
- **Documentation**: Important improvements have been made to the Kotlin documentation.

You can also watch this video of the Kotlin Language Evolution team discussing new features and answering questions:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 2.2.0 are bundled in the latest versions of IntelliJ IDEA and Android Studio. You don't need to update the Kotlin plugin in your IDE. All you need to do is to change the Kotlin version to 2.2.0 in your build scripts.

See Update to a new release for details.

Language

This release promotes guard conditions, non-local `break` and `continue`, and multi-dollar interpolation to Stable. Additionally, several features, such as context parameters and context-sensitive resolution, are introduced in preview.

Experimental

Preview of context parameters

Context parameters allow functions and properties to declare dependencies that are implicitly available in the surrounding context.

With context parameters, you don't need to manually pass around values, such as services or dependencies, that are shared and rarely change across sets of function calls.

Context parameters replace an older experimental feature called context receivers. To migrate from context receivers to context parameters, you can use assisted support in IntelliJ IDEA, as described in the blog post.

The main difference is that context parameters are not introduced as receivers in the body of a function. As a result, you need to use the name of the context parameters to access their members, unlike with context receivers, where the context is implicitly available.

Context parameters in Kotlin represent a significant improvement in managing dependencies through simplified dependency injection, improved DSL design, and scoped operations. For more information, see the feature's KEEP.

How to declare context parameters

You can declare context parameters for properties and functions using the `context` keyword followed by a list of parameters, each of the form `name: Type`. Here is an example with a dependency on the `UserService` interface:

```
// UserService defines the dependency required in the context
interface UserService {
    fun log(message: String)
    fun findUserById(id: Int): String
}

// Declares a function with a context parameter
context(users: UserService)
fun outputMessage(message: String) {
    // Uses log from the context
    users.log("Log: $message")
}

// Declares a property with a context parameter
context(users: UserService)
val firstUser: String
    // Uses findUserById from the context
    get() = users.findUserById(1)
```

You can use `_` as a context parameter name. In this case, the parameter's value is available for resolution but is not accessible by name inside the block:

```
// Uses "_" as context parameter name
context(_: UserService)
fun logWelcome() {
    // Finds the appropriate log function from UserService
    outputMessage("Welcome!")
}
```

How to enable context parameters

To enable context parameters in your project, use the following compiler option in the command line:

```
-Xcontext-parameters
```

Or add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xcontext-parameters")
    }
}
```

Specifying both `-Xcontext-receivers` and `-Xcontext-parameters` compiler options simultaneously leads to an error.

Leave your feedback

This feature is planned to be stabilized and improved in future Kotlin releases. We would appreciate your feedback on our issue tracker, YouTrack.

Experimental

Preview of context-sensitive resolution

Kotlin 2.2.0 introduces an implementation of context-sensitive resolution in preview.

You can find an overview of this feature in this video:

Watch video online.

Previously, you had to write the full name of enum entries or sealed class members, even when the type could be inferred from the context. For example:

```
enum class Problem {
    CONNECTION, AUTHENTICATION, DATABASE, UNKNOWN
}

fun message(problem: Problem): String = when (problem) {
    Problem.CONNECTION -> "connection"
    Problem.AUTHENTICATION -> "authentication"
    Problem.DATABASE -> "database"
    Problem.UNKNOWN -> "unknown"
}
```

Now, with context-sensitive resolution, you can omit the type name in contexts where the expected type is known:

```
enum class Problem {
    CONNECTION, AUTHENTICATION, DATABASE, UNKNOWN
}

// Resolves enum entries based on the known type of problem
fun message(problem: Problem): String = when (problem) {
    CONNECTION -> "connection"
    AUTHENTICATION -> "authentication"
    DATABASE -> "database"
    UNKNOWN -> "unknown"
}
```

The compiler uses this contextual type information to resolve the correct member. This information includes, among other things:

- The subject of a `when` expression
- An explicit return type
- A declared variable type
- Type checks (`is`) and casts (`as`)
- The known type of a sealed class hierarchy
- The declared type of a parameter

Context-sensitive resolution doesn't apply to functions, properties with parameters, or extension properties with receivers.

To try out context-sensitive resolution in your project, use the following compiler option in the command line:

```
-Xcontext-sensitive-resolution
```

Or add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xcontext-sensitive-resolution")
    }
}
```

We plan to stabilize and improve this feature in future Kotlin releases and would appreciate your feedback on our issue tracker YouTrack.

Experimental

Preview of features for annotation use-site targets

Kotlin 2.2.0 introduces a couple of features that make working with annotation use-site targets more convenient.

Experimental

`@all` meta-target for properties

Kotlin allows you to attach annotations to specific parts of a declaration, known as use-site targets. However, annotating each target individually was complex and error-prone:

```
data class User(
    val username: String,

    @param:Email      // Constructor parameter
    @field:Email      // Backing field
    @get:Email        // Getter method
    @property:Email   // Kotlin property reference
    val email: String,
) {
    @field:Email
    @get:Email
    @property:Email
    val secondaryEmail: String? = null
}
```

To simplify this, Kotlin introduces the new `@all` meta-target for properties. This feature tells the compiler to apply the annotation to all relevant parts of the property. When you use it, `@all` attempts to apply the annotation to:

- **`param`** : the constructor parameter, if declared in the primary constructor.
- **`property`** : the Kotlin property itself.
- **`field`** : the backing field, if it exists.
- **`get`** : the getter method.
- **`setparam`** : the parameter of the setter method, if the property is defined as `var` .
- **`RECORD_COMPONENT`** : if the class is a `@JvmRecord` , the annotation applies to the Java record component. This behavior mimics the way Java handles annotations on record components.

The compiler only applies the annotation to the targets for the given property.

In the example below, the `@Email` annotation is applied to all relevant targets of each property:

```
data class User(
    val username: String,

    // Applies @Email to param, property, field,
    // get, and setparam (if var)
    @all:Email val email: String,
) {
    // Applies @Email to property, field, and get
    // (no param since it's not in the constructor)
    @all:Email val secondaryEmail: String? = null
}
```

You can use the `@all` meta-target with any property, both inside and outside the primary constructor. However, you can't use the `@all` meta-target with multiple annotations.

This new feature simplifies the syntax, ensures consistency, and improves interoperability with Java records.

To enable the `@all` meta-target in your project, use the following compiler option in the command line:

```
-Xannotation-target-all
```

Or add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xannotation-target-all")
    }
}
```

This feature is in preview. Please report any problems to our issue tracker, YouTrack. For more information about the `@all` meta-target, read this KEEP proposal.

Experimental

New defaulting rules for use-site annotation targets

Kotlin 2.2.0 introduces new defaulting rules for propagating annotations to parameters, fields, and properties. Where previously an annotation was applied by default only to one of `param`, `property`, or `field`, defaults are now more in line with what is expected of an annotation.

If there are multiple applicable targets, one or more is chosen as follows:

- If the constructor parameter target (`param`) is applicable, it is used.
- If the property target (`property`) is applicable, it is used.
- If the field target (`field`) is applicable while `property` isn't, `field` is used.

If there are multiple targets, and none of `param`, `property`, or `field` are applicable, the annotation results in an error.

To enable this feature, add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xannotation-default-target=param-property")
    }
}
```

Or use the command-line argument for the compiler:

```
-Xannotation-default-target=param-property
```

Whenever you'd like to use the old behavior, you can:

- In a specific case, define the necessary target explicitly, for example, using `@param:Annotation` instead of `@Annotation`.
- For a whole project, use this flag in your Gradle build file:

  ```
  // build.gradle.kts
  kotlin {
      compilerOptions {
          freeCompilerArgs.add("-Xannotation-default-target=first-only")
      }
  }
  ```

This feature is in preview. Please report any problems to our issue tracker, YouTrack. For more information about the new defaulting rules for annotation use-site targets, read this KEEP proposal.

Beta

Support for nested type aliases

Kotlin 2.2.0 adds support for defining type aliases inside other declarations.

You can find an overview of this feature in this video:

Watch video online.

Previously, you could only declare type aliases at the top level of a Kotlin file. This meant that even internal or domain-specific type aliases had to live outside the class where they were used.

Starting from 2.2.0, you can define type aliases inside other declarations, as long as they don't capture type parameters from their outer class:

```
class Dijkstra {
    typealias VisitedNodes = Set<Node>

    private fun step(visited: VisitedNodes, ...) = ...
}
```

Nested type aliases have a few additional constraints, like not being able to mention type parameters. Check the documentation for the entire set of rules.

Nested type aliases allow for cleaner, more maintainable code by improving encapsulation, reducing package-level clutter, and simplifying internal implementations.

How to enable nested type aliases

To enable nested type aliases in your project, use the following compiler option in the command line:

```
-Xnested-type-aliases
```

Or add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xnested-type-aliases")
    }
}
```

Share your feedback

Nested type aliases are currently in Beta. Please report any problems to our issue tracker, YouTrack. For more information about this feature, read this KEEP proposal.

Stable features: Guard conditions, non-local `break` and `continue`, and multi-dollar interpolation

In Kotlin 2.1.0, several new language features were introduced in preview. We're happy to announce that the following language features are now Stable in this release:

- Guard conditions in `when` with a subject
- Non-local `break` and `continue`
- Multi-dollar interpolation: improved handling of `$` in string literals

See the full list of Kotlin language design features and proposals.

Experimental

Kotlin compiler: Unified management of compiler warnings

Kotlin 2.2.0 introduces a new compiler option, `-Xwarning-level`. It's designed to provide a unified way of managing compiler warnings in Kotlin projects.

Previously, you could only apply general module-wide rules, like disabling all warnings with `-nowarn`, turning all warnings to compilation errors with `-Werror`, or enabling additional compiler checks with `-Wextra`. The only option to adjust them for specific warnings was the `-Xsuppress-warning` option.

With the new solution, you can override general rules and exclude specific diagnostics in a consistent way.

How to apply

The new compiler option has the following syntax:

```
-Xwarning-level=DIAGNOSTIC_NAME:(error|warning|disabled)
```

- `error`: raises the specified warning to an error.
- `warning`: emits a warning and is enabled by default.

- `disabled` : completely suppresses the specified warning module-wide.

Keep in mind that you can only configure the severity level of *warnings* with the new compiler option.

Use cases

With the new solution, you can better fine-tune warning reporting in your project by combining general rules with specific ones. Choose your use case:

Suppress warnings

Command	Description
`-nowarn`	Suppresses all warnings during compilation.
`-Xwarning-level=DIAGNOSTIC_NAME:disabled`	Suppresses only specified warnings.
`-nowarn -Xwarning-level=DIAGNOSTIC_NAME:warning`	Suppresses all warnings except for the specified ones.

Raise warnings to errors

Command	Description
`-Werror`	Raises all warnings to compilation errors.
`-Xwarning-level=DIAGNOSTIC_NAME:error`	Raises only specified warnings to errors.
`-Werror -Xwarning-level=DIAGNOSTIC_NAME:warning`	Raises all warnings to errors except for the specified ones.

Enable additional compiler warnings

Command	Description
`-Wextra`	Enables all additional declaration, expression, and type compiler checks that emit warnings if true.
`-Xwarning-level=DIAGNOSTIC_NAME:warning`	Enables only specified additional compiler checks.
`-Wextra -Xwarning-level=DIAGNOSTIC_NAME:disabled`	Enables all additional checks except for the specified ones.

Warning lists

In case you have many warnings you want to exclude from general rules, you can list them in a separate file through `@argfile`.

Leave feedback

The new compiler option is still Experimental. Please report any problems to our issue tracker, YouTrack.

Kotlin/JVM

Kotlin 2.2.0 brings many updates to the JVM. The compiler now supports Java 24 bytecode and introduces changes to default method generation for interface functions. The release also simplifies working with annotations in Kotlin metadata, improves Java interop with inline value classes, and includes better support for annotating JVM records.

Changes to default method generation for interface functions

Starting from Kotlin 2.2.0, functions declared in interfaces are compiled to JVM default methods unless configured otherwise. This change affects how Kotlin's interface functions with implementations are compiled to bytecode.

This behavior is controlled by the new stable compiler option `-jvm-default`, replacing the deprecated `-Xjvm-default` option.

You can control the behavior of the `-jvm-default` option using the following values:

- `enable` (default): generates default implementations in interfaces and includes bridge functions in subclasses and `DefaultImpls` classes. Use this mode to maintain binary compatibility with older Kotlin versions.
- `no-compatibility`: generates only default implementations in interfaces. This mode skips compatibility bridges and `DefaultImpls` classes, making it suitable for new code.
- `disable`: disables default implementations in interfaces. Only bridge functions and `DefaultImpls` classes are generated, matching the behavior before Kotlin 2.2.0.

To configure the `-jvm-default` compiler option, set the `jvmDefault` property in your Gradle Kotlin DSL:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        jvmDefault = JvmDefaultMode.NO_COMPATIBILITY
    }
}
```

Experimental

Support for reading and writing annotations in Kotlin metadata

Previously, you had to read annotations from compiled JVM class files using reflection or bytecode analysis and manually match them to metadata entries based on signatures. This process was error-prone, especially for overloaded functions.

Now, in Kotlin 2.2.0, the Kotlin Metadata JVM library introduces support for reading annotations stored in Kotlin metadata.

To make annotations available in the metadata for your compiled files, add the following compiler option:

```
-Xannotations-in-metadata
```

Alternatively, add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xannotations-in-metadata")
    }
}
```

With this option enabled, the Kotlin compiler writes annotations into metadata alongside the JVM bytecode, making them accessible to the `kotlin-metadata-jvm` library.

The library provides the following APIs for accessing annotations:

- `KmClass.annotations`
- `KmFunction.annotations`
- `KmProperty.annotations`
- `KmConstructor.annotations`
- `KmPropertyAccessorAttributes.annotations`
- `KmValueParameter.annotations`
- `KmFunction.extensionReceiverAnnotations`
- `KmProperty.extensionReceiverAnnotations`
- `KmProperty.backingFieldAnnotations`
- `KmProperty.delegateFieldAnnotations`
- `KmEnumEntry.annotations`

These APIs are Experimental. To opt in, use the `@OptIn(ExperimentalAnnotationsInMetadata::class)` annotation.

Here's an example of reading annotations from Kotlin metadata:

```
@file:OptIn(ExperimentalAnnotationsInMetadata::class)

import kotlin.metadata.ExperimentalAnnotationsInMetadata
import kotlin.metadata.jvm.KotlinClassMetadata

annotation class Label(val value: String)

@Label("Message class")
class Message

fun main() {
    val metadata = Message::class.java.getAnnotation(Metadata::class.java)
    val kmClass = (KotlinClassMetadata.readStrict(metadata) as KotlinClassMetadata.Class).kmClass
    println(kmClass.annotations)
    // [@Label(value = StringValue("Message class"))]
}
```

If you use the `kotlin-metadata-jvm` library in your projects, we recommend testing and updating your code to support annotations. Otherwise, when annotations in metadata become enabled by default in a future Kotlin version, your projects may produce invalid or incomplete metadata.

If you experience any problems, please report them in our issue tracker.

Experimental

Improved Java interop with inline value classes

Kotlin 2.2.0 introduces a new experimental annotation: `@JvmExposeBoxed`. This annotation makes it easier to consume inline value classes from Java.

You can find an overview of this feature in this video:

Watch video online.

By default, Kotlin compiles inline value classes to use **unboxed representations**, which are more performant but often hard or even impossible to use from Java. For example:

```
@JvmInline value class PositiveInt(val number: Int) {
    init { require(number >= 0) }
}
```

In this case, because the class is unboxed, there is no constructor available for Java to call. There's also no way for Java to trigger the `init` block to ensure that `number` is positive.

When you annotate the class with `@JvmExposeBoxed`, Kotlin generates a public constructor that Java can call directly, ensuring that the `init` block also runs.

You can apply the `@JvmExposeBoxed` annotation at the class, constructor, or function level to gain fine-grained control over what's exposed to Java.

For example, in the following code, the extension function `.timesTwoBoxed()` is **not** accessible from Java:

```
@JvmInline
value class MyInt(val value: Int)

fun MyInt.timesTwoBoxed(): MyInt = MyInt(this.value * 2)
```

To make it possible to create an instance of the `MyInt` class and call the `.timesTwoBoxed()` function from Java code, add the `@JvmExposeBoxed` annotation to both the class and the function:

```
@JvmExposeBoxed
@JvmInline
value class MyInt(val value: Int)

@JvmExposeBoxed
fun MyInt.timesTwoBoxed(): MyInt = MyInt(this.value * 2)
```

With these annotations, the Kotlin compiler generates a Java-accessible constructor for the `MyInt` class. It also generates an overload for the extension function that uses the boxed form of the value class. As a result, the following Java code runs successfully:

```
MyInt input = new MyInt(5);
MyInt output = ExampleKt.timesTwoBoxed(input);
```

If you don't want to annotate every part of the inline value classes that you want to expose, you can effectively apply the annotation to a whole module. To apply this behavior to a module, compile it with the `-Xjvm-expose-boxed` option. Compiling with this option has the same effect as if every declaration in the module had the `@JvmExposeBoxed` annotation.

This new annotation does not change how Kotlin compiles or uses value classes internally, and all existing compiled code remains valid. It simply adds new capabilities to improve Java interoperability. The performance of Kotlin code using value classes is not impacted.

The `@JvmExposeBoxed` annotation is useful for library authors who want to expose boxed variants of member functions and receive boxed return types. It eliminates the need to choose between an inline value class (efficient but Kotlin-only) and a data class (Java-compatible but always boxed).

For a more detailed explanation of how the `@JvmExposedBoxed` annotation works and the problems it solves, see this KEEP proposal.

Improved support for annotating JVM records

Kotlin has supported JVM records since Kotlin 1.5.0. Now, Kotlin 2.2.0 improves how Kotlin handles annotations on record components, particularly in relation to Java's `RECORD_COMPONENT` target.

Firstly, if you want to use a `RECORD_COMPONENT` as an annotation target, you need to manually add annotations for Kotlin (`@Target`) and Java. This is because Kotlin's `@Target` annotation doesn't support `RECORD_COMPONENT`. For example:

```
@Target(AnnotationTarget.CLASS, AnnotationTarget.PROPERTY)
@java.lang.annotation.Target(ElementType.CLASS, ElementType.RECORD_COMPONENT)
annotation class exampleClass
```

Maintaining both lists manually can be error-prone, so Kotlin 2.2.0 introduces a compiler warning if the Kotlin and Java targets don't match. For instance, if you omit `ElementType.CLASS` in the Java target list, the compiler reports:

```
Incompatible annotation targets: Java target 'CLASS' missing, corresponding to Kotlin targets 'CLASS'.
```

Secondly, Kotlin's behavior differs from Java when it comes to propagating annotations in records. In Java, annotations on a record component automatically apply to the backing field, getter, and constructor parameter. Kotlin doesn't do this by default, but you can now replicate the behavior using the `@all:` use-site target.

For example:

```
@JvmRecord
data class Person(val name: String, @all:Positive val age: Int)
```

When you use `@JvmRecord` with `@all:`, Kotlin now:

- Propagates the annotation to the property, backing field, constructor parameter, and getter.
- Applies the annotation to the record component, as well, if the annotation supports Java's `RECORD_COMPONENT`.

Kotlin/Native

Starting with 2.2.0, Kotlin/Native uses LLVM 19. This release also brings several experimental features designed to track and adjust memory consumption.

Experimental

Per-object memory allocation

Kotlin/Native's memory allocator can now reserve memory on a per-object basis. In some cases, it may help you satisfy strict memory limitations or reduce memory consumption on the application's startup.

The new feature is designed to replace the `-Xallocator=std` compiler option, which enabled the system memory allocator instead of the default one. Now, you can disable buffering (paging of allocations) without switching memory allocators.

The feature is currently Experimental. To enable it, set the following option in your `gradle.properties` file:

```
kotlin.native.binary.pagedAllocator=false
```

Please report any problems to our issue tracker, YouTrack.

Experimental

Support for Latin-1 encoded strings at runtime

Kotlin now supports Latin-1-encoded strings, similarly to the JVM. This should help reduce the application's binary size and adjust memory consumption.

By default, strings in Kotlin are stored using UTF-16 encoding, where each character is represented by two bytes. In some cases, this leads to strings taking up twice as much space in the binary compared to the source code, and reading data from a simple ASCII file can take up twice as much memory as storing the file on disk.

In turn, Latin-1 (ISO 8859-1) encoding represents each of the first 256 Unicode characters with just one byte. With Latin-1 support enabled, strings are stored in Latin-1 encoding as long as all the characters fall within its range. Otherwise, the default UTF-16 encoding is used.

How to enable Latin-1 support

The feature is currently Experimental. To enable it, set the following option in your `gradle.properties` file:

```
kotlin.native.binary.latin1Strings=true
```

Known issues

As long as the feature is Experimental, the cinterop extension functions `String.pin` , `String.usePinned` , and `String.refTo` become less efficient. Each call to them may trigger automatic string conversion to UTF-16.

The Kotlin team is very grateful to our colleagues at Google and Sonya Valchuk in particular for implementing this feature.

For more information on memory consumption in Kotlin, see the documentation.

Improved tracking of memory consumption on Apple platforms

Starting with Kotlin 2.2.0, memory allocated by Kotlin code is now tagged. This can help you debug memory issues on Apple platforms.

When inspecting your application's high memory usage, you can now identify how much memory is reserved by Kotlin code. Kotlin's share is tagged with an identifier and can be tracked through tools like VM Tracker in Xcode Instruments.

This feature is enabled by default but is available only in the Kotlin/Native default memory allocator when *all* the following conditions are met:

- **Tagging enabled**. The memory should be tagged with a valid identifier. Apple recommends numbers between 240 and 255; the default value is 246.

  If you set up the `kotlin.native.binary.mmapTag=0` Gradle property, tagging is disabled.

- **Allocation with mmap**. The allocator should use the `mmap` system call to map files into memory.

  If you set up the `kotlin.native.binary.disableMmap=true` Gradle property, the default allocator uses `malloc` instead of `mmap`.

- **Paging enabled**. Paging of allocations (buffering) should be enabled.

  If you set up the `kotlin.native.binary.pagedAllocator=false` Gradle property, the memory is reserved on a per-object basis instead.

For more information on memory consumption in Kotlin, see the documentation.

LLVM update from 16 to 19

In Kotlin 2.2.0, we updated LLVM from version 16 to 19. The new version includes performance improvements, bug fixes, and security updates.

This update shouldn't affect your code, but if you encounter any issues, please report them to our issue tracker.

Windows 7 target deprecated

Starting with Kotlin 2.2.0, the minimal supported Windows version has been raised from Windows 7 to Windows 10. Since Microsoft ended support for Windows 7 in January 2025, we also decided to deprecate this legacy target.

For more information, see Kotlin/Native supported targets and hosts.

Kotlin/Wasm

In this release, the build infrastructure for the Wasm target is separated from the JavaScript target. Additionally, now you can configure the Binaryen tool per project or module.

Build infrastructure for Wasm target separated from JavaScript target

Before, the `wasmJs` target shared the same infrastructure as the `js` target. As a result, both targets were hosted in the same directory (`build/js`) and used the same NPM tasks and configurations.

Now, the `wasmJs` target has its own infrastructure separate from the `js` target. This allows Wasm tasks and types to be distinct from JavaScript ones, enabling independent configuration.

Additionally, Wasm-related project files and NPM dependencies are now stored in a separate `build/wasm` directory.

New NPM-related tasks have been introduced for Wasm, while existing JavaScript tasks are now dedicated only to JavaScript:

Wasm tasks	JavaScript tasks
`kotlinWasmNpmInstall`	`kotlinNpmInstall`
`wasmRootPackageJson`	`rootPackageJson`

Similarly, new Wasm-specific declarations have been added:

Wasm declarations	JavaScript declarations
`WasmNodeJsRootPlugin`	`NodeJsRootPlugin`
`WasmNodeJsPlugin`	`NodeJsPlugin`
`WasmYarnPlugin`	`YarnPlugin`
`WasmNodeJsRootExtension`	`NodeJsRootExtension`
`WasmNodeJsEnvSpec`	`NodeJsEnvSpec`
`WasmYarnRootEnvSpec`	`YarnRootEnvSpec`

You can now work with the Wasm target independently of the JavaScript target, which simplifies the configuration process.

This change is enabled by default and requires no additional setup.

Per-project Binaryen configuration

The Binaryen tool, used in Kotlin/Wasm to optimize production builds, was previously configured once in the root project.

Now, you can configure the Binaryen tool per project or module. This change aligns with Gradle's best practices and ensures better support for features like project isolation, improving build performance and reliability in complex builds.

Additionally, you can now configure different versions of Binaryen for different modules, if needed.

This feature is enabled by default. However, if you have a custom configuration of Binaryen, you now need to apply it per project, rather than only in the root project.

Kotlin/JS

This release improves the `copy()` function in `@JsPlainObject` interfaces, type aliases in files with the `@JsModule` annotation, and other Kotlin/JS features.

Fix for `copy()` in `@JsPlainObject` interfaces

Kotlin/JS has an experimental plugin called `js-plain-objects`, which introduced a `copy()` function for interfaces annotated with `@JsPlainObject`. You can use the `copy()` function to manipulate objects.

However, the initial implementation of `copy()` was not compatible with inheritance, and this caused issues when a `@JsPlainObject` interface extended other interfaces.

To avoid limitations on plain objects, the `copy()` function has been moved from the object itself to its companion object:

```
@JsPlainObject
external interface User {
    val name: String
    val age: Int
}

fun main() {
    val user = User(name = "SomeUser", age = 21)
    // This syntax is not valid anymore
    val copy = user.copy(age = 35)
    // This is the correct syntax
    val copy = User.copy(user, age = 35)
}
```

This change resolves conflicts in the inheritance hierarchy and eliminates ambiguity. It is enabled by default starting from Kotlin 2.2.0.

Support for type aliases in files with `@JsModule` annotation

Previously, files annotated with `@JsModule` to import declarations from JavaScript modules were restricted to external declarations only. This meant that you couldn't declare a `typealias` in such files.

Starting with Kotlin 2.2.0, you can declare type aliases inside files marked with `@JsModule`:

```
@file:JsModule("somepackage")
package somepackage
typealias SomeClass = Any
```

This change reduces an aspect of Kotlin/JS interoperability limitations, and more improvements are planned for future releases.

Support for type aliases in files with `@JsModule` is enabled by default.

Support for `@JsExport` in multiplatform `expect` declarations

When working with the `expect/actual` mechanism in Kotlin Multiplatform projects, it was not possible to use the `@JsExport` annotation for `expect` declarations in common code.

Starting with this release, you can apply `@JsExport` directly to `expect` declarations:

```
// commonMain

// Produced error, but now works correctly
@JsExport
expect class WindowManager {
    fun close()
}

@JsExport
fun acceptWindowManager(manager: WindowManager) {
    ...
}

// jsMain

@JsExport
actual class WindowManager {
    fun close() {
        window.close()
    }
}
```

You must also annotate with `@JsExport` the corresponding `actual` implementation in the JavaScript source set, and it has to use only exportable types.

This fix allows shared code defined in `commonMain` to be correctly exported to JavaScript. You can now expose your multiplatform code to JavaScript consumers without having to use manual workarounds.

This change is enabled by default.

Ability to use `@JsExport` with the `Promise<Unit>` type

Previously, when you tried to export a function returning the `Promise<Unit>` type with the `@JsExport` annotation, the Kotlin compiler produced an error.

While return types like `Promise<Int>` worked correctly, using `Promise<Unit>` triggered a "non-exportable type" warning, even though it correctly mapped to `Promise<void>` in TypeScript.

This restriction has been removed. Now, the following code compiles without error:

```
// Worked correctly before
@JsExport
fun fooInt(): Promise<Int> = GlobalScope.promise {
    delay(100)
    return@promise 42
}

// Produced error, but now works correctly
@JsExport
fun fooUnit(): Promise<Unit> = GlobalScope.promise {
    delay(100)
}
```

This change removes an unnecessary restriction in the Kotlin/JS interop model. This fix is enabled by default.

Gradle

Kotlin 2.2.0 is fully compatible with Gradle 7.6.3 through 8.14. You can also use Gradle versions up to the latest Gradle release. However, be aware that doing so may result in deprecation warnings, and some new Gradle features might not work.

In this release, the Kotlin Gradle plugin comes with several improvements to its diagnostics. It also introduces an experimental integration of binary compatibility validation, making it easier to work on libraries.

Experimental

Binary compatibility validation included in Kotlin Gradle plugin

To make it easier to check for binary compatibility between library versions, we're experimenting with moving the functionality of the binary compatibility validator into the Kotlin Gradle plugin (KGP). You can try it out in toy projects, but we don't recommend using it in production yet.

The original binary compatibility validator continues to be maintained during this experimental phase.

Kotlin libraries can use one of two binary formats: JVM class files or `klib`. Since these formats aren't compatible, the KGP works with each of them separately.

To enable the binary compatibility validation feature set, add the following to the `kotlin{}` block in your `build.gradle.kts` file:

```
// build.gradle.kts
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation {
        // Use the set() function to ensure compatibility with older Gradle versions
        enabled.set(true)
    }
}
```

If your project has multiple modules where you want to check for binary compatibility, configure the feature in each module separately. Each module can have its own custom configuration.

Once enabled, run the `checkLegacyAbi` Gradle task to check for binary compatibility issues. You can run the task in IntelliJ IDEA or from the command line in your project directory:

```
./gradlew checkLegacyAbi
```

This task generates an application binary interface (ABI) dump from the current code as a UTF-8 text file. The task then compares the new dump with the one from the previous release. If the task finds any differences, it reports them as errors. After reviewing the errors, if you decide the changes are acceptable, you can update the reference ABI dump by running the `updateLegacyAbi` Gradle task.

Filter classes

The feature lets you filter classes in the ABI dump. You can include or exclude classes explicitly by name or partial name, or by the annotations (or parts of annotation names) that mark them.

For example, this sample excludes all classes in the `com.company` package:

```
// build.gradle.kts
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation {
        filters.excluded.byNames.add("com.company.**")
    }
}
```

Explore the KGP API reference to learn more about configuring the binary compatibility validator.

Multiplatform limitations

In multiplatform projects, if your host doesn't support cross-compilation for all targets, the KGP tries to infer the ABI changes for unsupported targets by checking the ABI dumps from other ones. This approach helps avoid false validation failures if you later switch to a host that **can** compile all targets.

You can change this default behavior so that the KGP doesn't infer ABI changes for unsupported targets by adding the following to your `build.gradle.kts` file:

```
// build.gradle.kts
kotlin {
    @OptIn(org.jetbrains.kotlin.gradle.dsl.abi.ExperimentalAbiValidation::class)
    abiValidation {
        klib {
            keepUnsupportedTargets = false
        }
    }
}
```

However, if you have an unsupported target in your project, running the `checkLegacyAbi` task fails because the task can't create an ABI dump. This behavior may be desirable if it's more important for the check to fail than to miss an incompatible change due to inferred ABI changes from other targets.

Support for rich output in console for Kotlin Gradle plugin

In Kotlin 2.2.0, we support color and other rich output in the console during the Gradle build process, making it easier to read and understand the reported diagnostics.

Rich output is available in supported terminal emulators for Linux and macOS, and we're working on adding support for Windows.

```
Solutions:
 • It is unsupported, please stop using it.
 • History based incremental compilation approach for JVM platform is removed. Kotlin Gradle plugin is now usi

w: ⚠Usage of Internal Kotlin Gradle Plugin Properties Detected
ATTENTION! This build uses the following Kotlin Gradle Plugin properties:

kotlin.internal.suppress.buildToolsApiVersionConsistencyChecks

Internal properties are not recommended for production use.
Stability and future compatibility of the build is not guaranteed.
Solution:
Please consider using the public API instead of internal properties.

> Configure project :kotlin-dom-api-compat
w: 'kotlin-js' Gradle plugin is deprecated and will be removed in the future.
Please use 'kotlin("multiplatform")' plugin with a 'js()' target instead. See the migration guide: https://kot
<=------------> 13% CONFIGURING [50s]
```

Gradle console

This feature is enabled by default, but if you want to override it, add the following Gradle property to your `gradle.properties` file:

```
org.gradle.console=plain
```

For more information about this property and its options, see Gradle's documentation on Customizing log format.

Integration of Problems API within KGP diagnostics

Previously, the Kotlin Gradle Plugin (KGP) was only able to report diagnostics such as warnings and errors as plain text output to the console or logs.

Starting with 2.2.0, the KGP introduces an additional reporting mechanism: it now uses Gradle's Problems API, a standardized way to report rich, structured problem information during the build process.

The KGP diagnostics are now easier to read and more consistently displayed across different interfaces, such as the Gradle CLI and IntelliJ IDEA.

This integration is enabled by default, starting with Gradle 8.6 or later. As the API is still evolving, use the most recent Gradle version to benefit from the latest improvements.

KGP compatibility with `--warning-mode`

The Kotlin Gradle Plugin (KGP) diagnostics reported issues using fixed severity levels, meaning Gradle's `--warning-mode` command-line option had no effect on how the KGP displayed errors.

Now, the KGP diagnostics are compatible with the `--warning-mode` option, providing more flexibility. For example, you can convert all warnings into errors or disable warnings entirely.

With this change, the KGP diagnostics adjust the output based on the selected warning mode:

- When you set `--warning-mode=fail`, diagnostics with `Severity.Warning` are now elevated to `Severity.Error`.
- When you set `--warning-mode=none`, diagnostics with `Severity.Warning` are not logged.

This behavior is enabled by default starting with 2.2.0.

To ignore the `--warning-mode` option, set the following Gradle property to your `gradle.properties` file:

```
kotlin.internal.diagnostics.ignoreWarningMode=true
```

Experimental

New experimental build tools API

You can use Kotlin with various build systems, such as Gradle, Maven, Amper, and others. However, integrating Kotlin into each system to support the full feature set, such as incremental compilation and compatibility with Kotlin compiler plugins, daemons, and Kotlin Multiplatform, requires significant effort.

To simplify this process, Kotlin 2.2.0 introduces a new experimental build tools API (BTA). The BTA is a universal API that acts as an abstraction layer between build systems and the Kotlin compiler ecosystem. With this approach, each build system only needs to support a single BTA entry point.

Currently, the BTA supports Kotlin/JVM only. The Kotlin team at JetBrains already uses it in the Kotlin Gradle plugin (KGP) and the `kotlin-maven-plugin`. You can try the BTA through these plugins, but the API itself isn't ready yet for general use in your own build tool integrations. If you're curious about the BTA proposal or want to share your feedback, see this KEEP proposal.

To try the BTA in:

- The KGP, add the following property to your `gradle.properties` file:

```
kotlin.compiler.runViaBuildToolsApi=true
```

- Maven, you don't need to do anything. It's enabled by default.

The BTA currently has no direct benefits for the Maven plugin, but it lays a solid foundation for the faster delivery of new features, such as support for the Kotlin daemon and the stabilization of incremental compilation.

For the KGP, using the BTA already has the following benefits:

- Improved "in process" compiler execution strategy
- More flexibility to configure different compiler versions from Kotlin

Improved "in process" compiler execution strategy

The KGP supports three Kotlin compiler execution strategies. The "in process" strategy, which runs the compiler inside the Gradle daemon process, previously didn't support incremental compilation.

Now, using the BTA, the "in-process" strategy **does** support incremental compilation. To use it, add the following property to your `gradle.properties` file:

```
kotlin.compiler.execution.strategy=in-process
```

Flexibility to configure different compiler versions from Kotlin

Sometimes you might want to use a newer Kotlin compiler version in your code while keeping the KGP on an older one – for example, to try new language features while still working through build script deprecations. Or you might want to update the version of the KGP but keep an older Kotlin compiler version.

The BTA makes this possible. Here's how you can configure it in your `build.gradle.kts` file:

```kotlin
// build.gradle.kts
import org.jetbrains.kotlin.buildtools.api.ExperimentalBuildToolsApi
import org.jetbrains.kotlin.gradle.ExperimentalKotlinGradlePluginApi

plugins {
    kotlin("jvm") version "2.2.0"
}

group = "org.jetbrains.example"
version = "1.0-SNAPSHOT"

repositories {
    mavenCentral()
}

kotlin {
    jvmToolchain(8)
    @OptIn(ExperimentalBuildToolsApi::class, ExperimentalKotlinGradlePluginApi::class)
    compilerVersion.set("2.1.21") // Different version than 2.2.0
}
```

The BTA supports configuring the KGP and Kotlin compiler versions with the three previous major versions and one subsequent major version. So in KGP 2.2.0, Kotlin compiler versions 2.1.x, 2.0.x, and 1.9.25 are supported. KGP 2.2.0 is also compatible with future Kotlin compiler versions 2.2.x and 2.3.x.

However, keep in mind that using different compiler versions together with compiler plugins may lead to Kotlin compiler exceptions. The Kotlin team plans to address these kinds of problems in future releases.

Try out the BTA with these plugins and send us your feedback in the dedicated YouTrack tickets for the KGP and the Maven plugin.

Standard library

In Kotlin 2.2.0, the `Base64` API and `HexFormat` API are now Stable.

Stable Base64 encoding and decoding

Kotlin 1.8.20 introduced Experimental support for Base64 encoding and decoding. In Kotlin 2.2.0, the Base64 API is now Stable and includes four encoding schemes, with the new `Base64.Pem` added in this release:

- `Base64.Default` uses the standard Base64 encoding scheme.

  > The `Base64.Default` is the companion object of the `Base64` class. As a result, you can call its functions with `Base64.encode()` and `Base64.decode()` instead of `Base64.Default.encode()` and `Base64.Default.decode()`.

- `Base64.UrlSafe` uses the "URL and Filename safe" encoding scheme.
- `Base64.Mime` uses the MIME encoding scheme, inserting a line separator every 76 characters during encoding and skipping illegal characters during decoding.
- `Base64.Pem` encodes data like `Base64.Mime` but limits the line length to 64 characters.

You can use the Base64 API to encode binary data into a Base64 string and decode it back into bytes.

Here's an example:

```
val foBytes = "fo".map { it.code.toByte() }.toByteArray()
Base64.Default.encode(foBytes) // "Zm8="
// Alternatively:
// Base64.encode(foBytes)

val foobarBytes = "foobar".map { it.code.toByte() }.toByteArray()
Base64.UrlSafe.encode(foobarBytes) // "Zm9vYmFy"

Base64.Default.decode("Zm8=") // foBytes
// Alternatively:
// Base64.decode("Zm8=")

Base64.UrlSafe.decode("Zm9vYmFy") // foobarBytes
```

On the JVM, use the `.encodingWith()` and `.decodingWith()` extension functions to encode and decode Base64 with input and output streams:

```
import kotlin.io.encoding.*
import java.io.ByteArrayOutputStream

fun main() {
    val output = ByteArrayOutputStream()
    val base64Output = output.encodingWith(Base64.Default)

    base64Output.use { stream ->
        stream.write("Hello World!!".encodeToByteArray())
    }

    println(output.toString())
    // SGVsbG8gV29ybGQhIQ==
}
```

Stable Hexadecimal parsing and formatting with the `HexFormat` API

The `HexFormat` API introduced in Kotlin 1.9.0 is now Stable. You can use it to convert between numerical values and hexadecimal strings.

For example:

```
fun main() {
        println(93.toHexString())
    //sampleEnd
}
```

For more information, see New HexFormat class to format and parse hexadecimals.

Compose compiler

In this release, the Compose compiler introduces support for composable function references and changes defaults for several feature flags.

Support for `@Composable` function references

The Compose compiler supports the declaration and usage of composable function references starting from the Kotlin 2.2.0 release:

```
val content: @Composable (String) -> Unit = ::Text

@Composable fun App() {
    content("My App")
}
```

Composable function references behave slightly differently from composable lambda objects at runtime. In particular, composable lambdas allow for finer control over skipping by extending the `ComposableLambda` class. Function references are expected to implement the `KCallable` interface, so the same optimization cannot be applied to them.

`PausableComposition` feature flag enabled by default

The `PausableComposition` feature flag is enabled by default starting from Kotlin 2.2.0. This flag adjusts the Compose compiler output for restartable functions, allowing runtime to force skipping behavior and therefore effectively pause composition by skipping each function. This allows heavy compositions to be split between frames, which will be used by prefetching in a future release.

To disable this feature flag, add the following to your Gradle configuration:

```
// build.gradle.kts
composeCompiler {
    featureFlag = setOf(ComposeFeatureFlag.PausableComposition.disabled())
}
```

`OptimizeNonSkippingGroups` feature flag enabled by default

The `OptimizeNonSkippingGroups` feature flag is enabled by default starting from Kotlin 2.2.0. This optimization improves runtime performance by removing group calls generated for non-skipping composable functions. It should not result in any observable behavior changes at runtime.

If you encounter any issues, you can validate that this change causes the issue by disabling the feature flag. Please report any issues to the Jetpack Compose issue tracker.

To disable the `OptimizeNonSkippingGroups` flag, add the following to your Gradle configuration:

```
composeCompiler {
    featureFlag = setOf(ComposeFeatureFlag.OptimizeNonSkippingGroups.disabled())
}
```

Deprecated feature flags

The `StrongSkipping` and `IntrinsicRemember` feature flags are now deprecated and will be removed in a future release. If you encounter any issues that make you disable these feature flags, please report them to the Jetpack Compose issue tracker.

Breaking changes and deprecations

This section highlights important breaking changes and deprecations worth noting. See our Compatibility guide for a complete overview of all breaking changes and deprecations in this release.

-

Starting with Kotlin 2.2.0, the compiler no longer supports `-language-version=1.6` or `-language-version=1.7`. Language feature sets older than 1.8 aren't supported but the language itself remains fully backward compatible with Kotlin 1.0.

- Support for the Ant build system is deprecated. Kotlin support for Ant hasn't been in active development for a long time, and there are no plans to maintain it further due to its relatively small user base. We plan to remove Ant support in 2.3.0.
- Kotlin 2.2.0 raises the deprecation level of the `kotlinOptions{}` block in Gradle to error. Use the `compilerOptions{}` block instead. For guidance on updating your build scripts, see Migrate from `kotlinOptions{}` to `compilerOptions{}`.
- Kotlin scripting remains an important part of Kotlin's ecosystem, but we're focusing on specific use cases such as custom scripting, as well as `gradle.kts` and `main.kts` scripts, to provide a better experience. To learn more, see our updated blog post. As a result, Kotlin 2.2.0 deprecates support for:
  - REPL: To continue to use REPL via `kotlinc`, opt in with the `-Xrepl` compiler option.
  - JSR-223: Since this JSR is in the **Withdrawn** state, the JSR-223 implementation continues to work with language version 1.9 but won't be migrated to use the K2 compiler in the future.
  - The `KotlinScriptMojo` Maven plugin: We didn't see enough traction with this plugin. You will see compiler warnings if you continue to use it.
- In Kotlin 2.2.0, the `setSource()` function in `KotlinCompileTool` now replaces configured sources instead of adding to them. If you want to add sources without replacing existing ones, use the `source()` function.
- The type of `annotationProcessorOptionProviders` in `BaseKapt` has been changed from `MutableList<Any>` to `MutableList<CommandLineArgumentProvider>`. If your code currently adds a list as a single element, use the `addAll()` function instead of the `add()` function.
- Following the deprecation of the dead code elimination (DCE) tool used in the legacy Kotlin/JS backend, the remaining DSLs related to DCE are now removed from the Kotlin Gradle plugin:
  - The `org.jetbrains.kotlin.gradle.dsl.KotlinJsDce` interface
  - The `org.jetbrains.kotlin.gradle.targets.js.dsl.KotlinJsBrowserDsl.dceTask(body: Action<KotlinJsDce>)` function
  - The `org.jetbrains.kotlin.gradle.dsl.KotlinJsDceCompilerToolOptions` interface
  - The `org.jetbrains.kotlin.gradle.dsl.KotlinJsDceOptions` interface

  The current JS IR compiler supports DCE out of the box, and the `@JsExport` annotation allows specifying which Kotlin functions and classes to retain during DCE.
- The deprecated `kotlin-android-extensions` plugin is removed in Kotlin 2.2.0. Use the `kotlin-parcelize` plugin for the `Parcelable` implementation generator and the Android Jetpack's view bindings for synthetic views instead.
- Experimental `kotlinArtifacts` API is deprecated in Kotlin 2.2.0. Use the current DSL available in the Kotlin Gradle plugin to build final native binaries. If it's not sufficient for migration, leave a comment in this YouTrack issue.
- `KotlinCompilation.source`, deprecated in Kotlin 1.9.0, is now removed from the Kotlin Gradle plugin.
- The parameters for experimental commonization modes are deprecated in Kotlin 2.2.0. Clear the commonization cache to delete invalid compilation artifacts.

- The deprecated `konanVersion` property is now removed from the `CInteropProcess` task. Use `CInteropProcess.kotlinNativeVersion` instead.
- Usage of the deprecated `destinationDir` property will now lead to an error. Use `CInteropProcess.destinationDirectory.set()` instead.

Documentation updates

This release brings notable documentation changes, including the migration of Kotlin Multiplatform documentation to the KMP portal.

Additionally, we created new pages and tutorials, and revamped existing ones.

New and revamped tutorials

- Kotlin intermediate tour – Take your understanding of Kotlin to the next level. Learn when to use extension functions, interfaces, classes, and more.
- Build a Kotlin app that uses Spring AI – Learn how to create a Kotlin app that answers questions using OpenAI and a vector database.
- Create a Spring Boot project with Kotlin – Learn how to create a Spring Boot project with Gradle using IntelliJ IDEA's **New Project** wizard.
- Mapping Kotlin and C tutorial series – Learn how different types and constructs are mapped between Kotlin and C.
- Create an app using C interop and libcurl – Create a simple HTTP client that can run natively using the libcurl C library.
- Create your Kotlin Multiplatform library – Learn how to create and publish a multiplatform library using IntelliJ IDEA.
- Build a full-stack application with Ktor and Kotlin Multiplatform – This tutorial now uses IntelliJ IDEA instead of Fleet, along with Material 3 and the latest versions of Ktor and Kotlin.
- Manage local resource environment in your Compose Multiplatform app – Learn how to manage the application's resource environment, like in-app theme and language.

New and revamped pages

- Kotlin for AI overview – Discover Kotlin's capabilities for building AI-powered applications.
- Dokka migration guide – Learn how to migrate to v2 of the Dokka Gradle plugin.
- Kotlin Metadata JVM library – Explore guidance on reading, modifying, and generating metadata for Kotlin classes compiled for the JVM.
- CocoaPods integration – Learn how to set up the environment, add Pod dependencies, or use a Kotlin project as a CocoaPod dependency through tutorials and sample projects.
- New pages for Compose Multiplatform to support the iOS stable release:
  - Navigation and Deep linking in particular.
  - Implementing layouts in Compose.
  - Localizing strings and other i18n pages like support for RTL languages.

- Compose Hot Reload – Learn how to use Compose Hot Reload with your desktop targets and how to add it to an existing project.
- Exposed migrations – Learn about the tools Exposed provides for managing database schema changes.

How to update to Kotlin 2.2.0

The Kotlin plugin is distributed as a bundled plugin in IntelliJ IDEA and Android Studio.

To update to the new Kotlin version, change the Kotlin version to 2.2.0 in your build scripts.

Compatibility guide for Kotlin 2.2.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 2.1 to Kotlin 2.2.

Basic terms

In this document, we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Drop support in `-language-version` for 1.6 and 1.7

Issue: KT-71793

Component: Compiler

Incompatible change type: source

Short summary: Starting with Kotlin 2.2, the compiler no longer supports `-language-version=1.6` or `-language-version=1.7`. This means that language feature sets older than 1.8 are no longer supported. However, the language itself remains fully backward compatible with Kotlin 1.0.

Deprecation cycle:

- 2.1.0: report a warning when using `-language-version` with versions 1.6 and 1.7
- 2.2.0: report a warning when using `-language-version` with versions 1.8 and 1.9; raise the warning to an error for versions 1.6 and 1.7

Enable invokedynamic for annotated lambdas by default

Issue: KTLC-278

Component: Core language

Incompatible change type: behavioral

Short summary: Lambdas with annotations now use `invokedynamic` through `LambdaMetafactory` by default, aligning their behavior with Java lambdas. This affects reflection-based code that relied on retrieving annotations from generated lambda classes. To revert to the old behavior, use the `-Xindy-allow-annotated-lambdas=false` compiler option.

Deprecation cycle:

- 2.2.0: enable `invokedynamic` for annotated lambdas by default

Prohibit constructor call and inheritance on type aliases with variance in expanded types in K2

Issue: KTLC-4

Component: Core language

Incompatible change type: source

Short summary: Constructor calls and inheritance using type aliases that expand to types that use variance modifiers such as `out` are no longer supported by the K2 compiler. This resolves inconsistencies where using the original type wasn't allowed, but the same usage through a type alias was permitted. To migrate, use the original type explicitly where needed.

Deprecation cycle:

- 2.0.0: report a warning for constructor calls or supertype usage on type aliases that expand to types with variance modifiers
- 2.2.0: raise the warning to an error

Prohibit synthetic properties from Kotlin getters

Issue: KTLC-272

Component: Core language

Incompatible change type: source

Short summary: Synthetic properties are no longer allowed for getters defined in Kotlin. This affects cases where Java classes extend Kotlin ones and when working with mapped types like `java.util.LinkedHashSet`. To migrate, replace property access with direct calls to the corresponding getter functions.

Deprecation cycle:

- 2.0.0: report a warning for accessing synthetic properties created from Kotlin getters
- 2.2.0: raise the warning to an error

Change default method generation for interface functions on JVM

Issue: KTLC-269

Component: Core language

Incompatible change type: binary

Short summary: Functions declared in interfaces are now compiled to JVM default methods unless configured otherwise. This may result in compilation errors in Java code when unrelated supertypes define conflicting implementations. The behavior is controlled by the stable `-jvm-default` compiler option, which replaces the now deprecated `-Xjvm-default` option. To restore the previous behavior, where default implementations are generated only in `DefaultImpls` classes and subclasses, use `-jvm-default=disable`.

Deprecation cycle:

- 2.2.0: `-jvm-default` compiler option is set to `enable` by default

Forbid field-targeted annotations on annotation properties

Issue: KTLC-7

Component: Core language

Incompatible change type: source

Short summary: Field-targeted annotations are no longer allowed on annotation properties. Although these annotations had no observable effect, this change may affect custom IR plugins that relied on them. To migrate, remove the field-targeted annotation from the property.

Deprecation cycle:

- 2.1.0: `@JvmField` annotation is deprecated with a warning on annotation properties
- 2.1.20: report a warning for all field-targeted annotations on annotation properties
- 2.2.0: raise the warning to an error

Forbid reified type parameters in type aliases

Issue: KTLC-5

Component: Core language

Incompatible change type: source

Short summary: The `reified` modifier is no longer allowed on type parameters in type aliases. Reified type parameters are only valid in inline functions, so using them in type aliases had no effect. To migrate, remove the `reified` modifier from `typealias` declarations.

Deprecation cycle:

- 2.1.0: report a warning for reified type parameters in type aliases
- 2.2.0: raise the warning to an error

Correct type checks on inline value classes for `Number` and `Comparable`

Issue: KTLC-21

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Inline value classes are no longer treated as implementors of `java.lang.Number` or `java.lang.Comparable` in `is` and `as` checks. These checks previously returned incorrect results when applied to boxed inline classes. The optimization now applies only to primitive types and their wrappers.

Deprecation cycle:

- 2.2.0: enable the new behavior

Prohibit inaccessible generic types from indirect dependencies

Issue: KTLC-3

Component: Core language

Incompatible change type: source

Short summary: The K2 compiler now reports errors when using types from indirect dependencies that are not visible to the compiler. This affects cases such as lambda parameters or generic type arguments, where the referenced type is not available due to a missing dependency.

Deprecation cycle:

- 2.0.0: report errors for inaccessible generic types in lambdas and selected usages of inaccessible generic type arguments; report warnings for inaccessible non-generic types in lambdas and inaccessible type arguments in expression and super types
- 2.1.0: raise the warning on inaccessible non-generic types in lambdas to an error
- 2.2.0: raise the warning on inaccessible type arguments in expression types to an error

Enforce visibility checks on type parameter bounds

Issue: KTLC-274

Component: Core language

Incompatible change type: source

Short summary: Functions and properties can no longer use a type parameter bound that has more restrictive visibility than the declaration itself. This prevents exposing inaccessible types indirectly, which previously compiled without errors but led to runtime failures or IR validation errors in some cases.

Deprecation cycle:

- 2.1.0: report a warning when a type parameter has a bound that is not visible from the declaration's visibility scope
- 2.2.0: raise the warning to an error

Report errors when exposing private types in non-private inline functions

Issue: KT-70916

Component: Core language

Incompatible change type: source

Short summary: Accessing private types, functions, or properties from non-private inline functions is no longer allowed. To migrate, either avoid referencing private entities, make the function private, or remove the `inline` modifier. Note that removing `inline` breaks binary compatibility.

Deprecation cycle:

- 2.2.0: report an error when accessing private types or members from non-private inline functions

Forbid non-local returns in lambdas used as parameter's default value

Issue: KTLC-286

Component: Core language

Incompatible change type: source

Short summary: Non-local return statements are no longer allowed in lambdas used as parameter's default value. This pattern previously compiled but led to runtime crashes. To migrate, rewrite the lambda to avoid non-local returns or move the logic outside the default value.

Deprecation cycle:

- 2.2.0: report an error for non-local returns in lambdas used as parameter's default value

Standard library

Deprecate `kotlin.native.Throws`

Issue: KT-72137

Component: Kotlin/Native

Incompatible change type: source

Short summary: `kotlin.native.Throws` is deprecated; use the common `kotlin.Throws` annotation instead.

Deprecation cycle:

- 1.9.0: report a warning when using `kotlin.native.Throws`
- 2.2.0: raise the warning to an error

Deprecate `AbstractDoubleTimeSource`

Issue: KT-72137

Component: kotlin-stdlib

Incompatible change type: source

Short summary: `AbstractDoubleTimeSource` is deprecated; use `AbstractLongTimeSource` instead.

Deprecation cycle:

- 1.8.20: report a warning when using `AbstractDoubleTimeSource`
- 2.2.0: raise the warning to an error

Tools

Correct `setSource()` function in `KotlinCompileTool` to replace sources

Issue: KT-59632

Component: Gradle

Incompatible change type: behavioral

Short summary: The `setSource()` function in the `KotlinCompileTool` interface now replaces configured sources instead of adding to them. If you want to add sources without replacing existing ones, use the `source()` function.

Deprecation cycle:

- 2.2.0: enable the new behavior

Deprecate `KotlinCompilationOutput#resourcesDirProvider` property

Issue: KT-70620

Component: Gradle

Incompatible change type: source

Short summary: The `KotlinCompilationOutput#resourcesDirProvider` property is deprecated. Use `KotlinSourceSet.resources` in your Gradle build script instead to add additional resource directories.

Deprecation cycle:

- 2.1.0: `KotlinCompilationOutput#resourcesDirProvider` is deprecated with a warning
- 2.2.0: raise the warning to an error

Deprecate `BaseKapt.annotationProcessorOptionProviders` property

Issue: KT-58009

Component: Gradle

Incompatible change type: source

Short summary: The `BaseKapt.annotationProcessorOptionProviders` property is deprecated in favor of `BaseKapt.annotationProcessorOptionsProviders`, which accepts a `ListProperty<CommandLineArgumentProvider>` instead of a `MutableList<Any>`. This clearly defines the expected element type and prevents runtime failures caused by adding incorrect elements, such as nested lists. If your current code adds a list as a single element, replace the `add()` function with the `addAll()` function.

Deprecation cycle:

- 2.2.0: enforce the new type in the API

Deprecate `kotlin-android-extensions` plugin

Issue: KT-72341

Component: Gradle

Incompatible change type: source

Short summary: The `kotlin-android-extensions` plugin is deprecated. Use a separate plugin, `kotlin-parcelize`, for the `Parcelable` implementation generator and the Android Jetpack's view bindings for synthetic views instead.

Deprecation cycle:

- 1.4.20: the plugin is deprecated
- 2.1.20: a configuration error is introduced, and no plugin code is executed
- 2.2.0: the plugin code is removed
- 2.4.0: remove the plugin ID

Deprecate `kotlinOptions` DSL

Issue: KT-54110

Component: Gradle

Incompatible change type: source

Short summary: The ability to configure compiler options through the `kotlinOptions` DSL and the related `KotlinCompile<KotlinOptions>` task interface is deprecated in favor of the new `compilerOptions` DSL. As part of this deprecation, all properties in the `kotlinOptions` interface are now also individually marked as deprecated. To migrate, use the `compilerOptions` DSL to configure compiler options. For guidance on the migration, see Migrate from `kotlinOptions {}` to `compilerOptions {}`.

Deprecation cycle:

- 2.0.0: report a warning for `kotlinOptions` DSL
- 2.2.0: raise the warning to an error and deprecate all properties in `kotlinOptions`

Remove `kotlin.incremental.useClasspathSnapshot` property

Issue: KT-62963

Component: Gradle

Incompatible change type: source

Short summary: The `kotlin.incremental.useClasspathSnapshot` Gradle property is removed. This property controlled the deprecated JVM history-based incremental compilation mode, which has been replaced by the classpath-based approach enabled by default since Kotlin 1.8.20.

Deprecation cycle:

- 2.0.20: deprecate the `kotlin.incremental.useClasspathSnapshot` property with a warning
- 2.2.0: remove the property

Deprecations to Kotlin scripting

Issues: KT-71685, KT-75632, KT-76196.

Component: Scripting

Incompatible change type: source

Short summary: Kotlin 2.2.0 deprecates support for:

- REPL: To continue to use REPL via `kotlinc`, opt in with the `-Xrepl` compiler option.
- JSR-223: Since the JSR is in **Withdrawn** state. The JSR-223 implementation continues to work with language version 1.9 but there are no plans to migrate to the K2 compiler in the future.
- The `KotlinScriptMojo` Maven plugin. You will see compiler warnings if you continue to use it.

For more information, see our blog post.

Deprecation cycle:

- 2.1.0: deprecate the use of REPL in `kotlinc` with a warning
- 2.2.0: to use REPL via `kotlinc`, opt in with the `-Xrepl` compiler option; deprecate JSR-223, support can be restored by switching to language version 1.9; deprecate the `KotlinScriptMojo` Maven plugin
- 2.4.0: remove Kotlin script execution through the `KotlinScriptMojo` Maven plugin

Deprecate disambiguation classifier properties

Issue: KT-58231

Component: Gradle

Incompatible change type: source

Short summary: Options that were used to control how the Kotlin Gradle plugin disambiguates source set names and IDE imports became obsolete. Therefore, the following properties are now deprecated in the `KotlinTarget` interface:

- `useDisambiguationClassifierAsSourceSetNamePrefix`
- `overrideDisambiguationClassifierOnIdeImport`

Deprecation cycle:

- 2.0.0: report a warning when the Gradle properties are used
- 2.1.0: raise this warning to an error
- 2.2.0: remove Gradle properties

Deprecate commonization parameters

Issue: KT-75161

Component: Gradle

Incompatible change type: source

Short summary: The parameters for experimental commonization modes are deprecated in the Kotlin Gradle plugin. These parameters may produce invalid compilation artifacts that are then cached. To delete affected artifacts:

1. Remove the following options from your `gradle.properties` file:

   ```
   kotlin.mpp.enableOptimisticNumberCommonization
   kotlin.mpp.enablePlatformIntegerCommonization
   ```

2. Clear the commonization cache in the `~/.konan/*/klib/commonized` directory or run the following command:

   ```
   ./gradlew cleanNativeDistributionCommonization
   ```

Deprecation cycle:

- 2.2.0: deprecate commonization parameters with an error
- 2.2.20: remove commonization parameters

Deprecate support for legacy metadata compilation

Issue: KT-61817

Component: Gradle

Incompatible change type: source

Short summary: Options that were used to set up hierarchical structure and create intermediate source sets between the common and intermediate source sets became obsolete. The following compiler options are removed:

- `isCompatibilityMetadataVariantEnabled`
- `withGranularMetadata`
- `isKotlinGranularMetadataEnabled`

Deprecation cycle:

- 2.2.0: remove compiler options from the Kotlin Gradle plugin

Deprecate `KotlinCompilation.source` API

Issue: KT-64991

Component: Gradle

Incompatible change type: source

Short summary: The access to `KotlinCompilation.source` API that allowed adding Kotlin source sets directly to the Kotlin compilation has been deprecated.

Deprecation cycle:

- 1.9.0: report a warning when `KotlinCompilation.source` is used
- 1.9.20: raise this warning to an error
- 2.2.0: remove `KotlinCompilation.source` from the Kotlin Gradle plugin; attempts to use it lead to "unresolved reference" errors during the buildscript compilation

Deprecate target presets APIs

Issue: KT-71698

Component: Gradle

Incompatible change type: source

Short summary: Target presets for Kotlin Multiplatform targets became obsolete; target DSL functions like `jvm()` or `iosSimulatorArm64()` now cover the same use cases. All presets-related APIs are deprecated:

- The `presets` property in `org.jetbrains.kotlin.gradle.dsl.KotlinMultiplatformExtension`
- The `org.jetbrains.kotlin.gradle.plugin.KotlinTargetPreset` interface and all its inheritors
- The `fromPreset` overloads

Deprecation cycle:

- 1.9.20: report a warning on any usages of the presets-related API
- 2.0.0: raise this warning to an error
- 2.2.0: remove the presets-related API from the public API of the Kotlin Gradle plugin; sources that still use it fail with "unresolved reference" errors, and binaries (for example, Gradle plugins) might fail with linkage errors unless recompiled against the latest versions of the Kotlin Gradle plugin

Deprecate Apple target shortcuts

Issue: KT-70615

Component: Gradle

Incompatible change type: source

Short summary: The `ios()`, `watchos()`, and `tvos()` target shortcuts are deprecated in Kotlin Multiplatform DSL. The shortcuts were designed to partially create a source set hierarchy for Apple targets. The Kotlin Multiplatform Gradle plugin now provides a built-in hierarchy template. Instead of shortcuts, specify the list of targets, and then the plugin automatically sets up intermediate source sets for them.

Deprecation cycle:

- 1.9.20: report a warning when target shortcuts are used; the default hierarchy template is enabled by default instead
- 2.1.0: report an error when target shortcuts are used
- 2.2.0: remove target shortcut DSL from the Kotlin Multiplatform Gradle plugin

Deprecate `publishAllLibraryVariants()` function

Issue: KT-60623

Component: Gradle

Incompatible change type: source

Short summary: The `publishAllLibraryVariants()` function is deprecated. It was designed to publish all build variants for Android targets. This approach is not recommended now, as it can cause problems with variant resolution, especially when multiple flavors and build types are used. Use the `publishLibraryVariants()` function, which specifies build variants, instead.

Deprecation cycle:

- 2.2.0: `publishAllLibraryVariants()` is deprecated

Deprecate `android` target

Issue: KT-71608

Component: Gradle

Incompatible change type: source

Short summary: The `android` target name is deprecated in the current Kotlin DSL. Use `androidTarget` instead.

Deprecation cycle:

- 1.9.0: introduce a deprecation warning when the `android` name is used in Kotlin Multiplatform projects
- 2.1.0: raise this warning to an error
- 2.2.0: remove the `android` target DSL from the Kotlin Multiplatform Gradle plugin

Deprecate `konanVersion` in `CInteropProcess`

Issue: KT-71069

Component: Gradle

Incompatible change type: source

Short summary: The `konanVersion` property in the `CInteropProcess` task is deprecated. Use `CInteropProcess.kotlinNativeVersion` instead.

Deprecation cycle:

- 2.1.0: report a warning when the `konanVersion` property is used
- 2.2.0: raise this warning to an error
- 2.3.0: remove the `konanVersion` property from the Kotlin Gradle plugin

Deprecate `destinationDir` in `CInteropProcess`

Issue: KT-71068

Component: Gradle

Incompatible change type: source

Short summary: The `destinationDir` property in the `CInteropProcess` task is deprecated. Use the `CInteropProcess.destinationDirectory.set()` function instead.

Deprecation cycle:

- 2.1.0: report a warning when the `destinationDir` property is used
- 2.2.0: raise this warning to an error
- 2.3.0: remove the `destinationDir` property from the Kotlin Gradle plugin

Deprecate `kotlinArtifacts` API

Issue: KT-74953

Component: Gradle

Incompatible change type: source

Short summary: The experimental `kotlinArtifacts` API is deprecated. Use the current DSL available in the Kotlin Gradle plugin to build final native binaries. If it's not sufficient for migration, leave a comment in this YouTrack issue.

Deprecation cycle:

- 2.2.0: report a warning when the `kotlinArtifacts` API is used
- 2.3.0: raise this warning to an error

What's new in Kotlin 2.1.20

Released: March 20, 2025

The Kotlin 2.1.20 release is here! Here are the main highlights:

- **K2 compiler updates**: Updates to the new kapt and Lombok plugins
- **Kotlin Multiplatform**: New DSL to replace Gradle's Application plugin
- **Kotlin/Native**: Support for Xcode 16.3 and a new inlining optimization
- **Kotlin/Wasm**: Default custom formatters, support for DWARF, and migration to Provider API
- **Gradle support**: Compatibility with Gradle's Isolated Projects and custom publication variants
- **Standard library**: Common atomic types, improved UUID support, and new time-tracking functionality
- **Compose compiler**: Relaxed restrictions on `@Composable` functions and other updates
- **Documentation**: Important improvements to the Kotlin documentation

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 2.1.20 are bundled in the latest IntelliJ IDEA and Android Studio. You don't need to update the Kotlin plugin in your IDE. All you need to do is to change the Kotlin version to 2.1.20 in your build scripts.

See Update to a new release for details.

Download sources for Kotlin artifacts in projects with OSGi support

Sources of all dependencies of the `kotlin-osgi-bundle` library are now included in its distribution. This allows IntelliJ IDEA to download these sources to provide documentation for Kotlin symbols and improve the debugging experience.

Kotlin K2 compiler

We're continuing to improve plugin support for the new Kotlin K2 compiler. This release brings updates to the new kapt and Lombok plugins.

Beta

New default kapt plugin

Starting with Kotlin 2.1.20, the K2 implementation of the kapt compiler plugin is enabled by default for all the projects.

The JetBrains team launched the new implementation of the kapt plugin with the K2 compiler back in Kotlin 1.9.20. Since then, we have further developed the internal implementation of K2 kapt and made its behavior similar to that of the K1 version, while significantly improving its performance as well.

If you encounter any issues when using kapt with the K2 compiler, you can temporarily revert to the previous plugin implementation.

To do this, add the following option to the `gradle.properties` file of your project:

```
kapt.use.k2=false
```

Please report any issues to our issue tracker.

Experimental

Lombok compiler plugin: support for `@SuperBuilder` and updates on `@Builder`

The Kotlin Lombok compiler plugin now supports the `@SuperBuilder` annotation, making it easier to create builders for class hierarchies. Previously, developers using Lombok in Kotlin had to manually define builders when working with inheritance. With `@SuperBuilder`, the builder automatically inherits superclass fields, allowing you to initialize them when constructing an object.

Additionally, this update includes several improvements and bug fixes:

- The `@Builder` annotation now works on constructors, allowing more flexible object creation. For more details, see the corresponding YouTrack issue.
- Several issues related to Lombok's code generation in Kotlin have been resolved, improving overall compatibility. For more details, see the GitHub changelog.

For more information about the `@SuperBuilder` annotation, see the official Lombok documentation.

Experimental

Kotlin Multiplatform: new DSL to replace Gradle's Application plugin

Starting with Gradle 8.7, the Application plugin is no longer compatible with the Kotlin Multiplatform Gradle plugin. Kotlin 2.1.20 introduces an Experimental DSL to achieve similar functionality. The new `executable {}` block configures execution tasks and Gradle distributions for JVM targets.

Before the `executable {}` block in your build script, add the following `@OptIn` annotation:

```
@OptIn(ExperimentalKotlinGradlePluginApi::class)
```

For example:

```
kotlin {
    jvm {
        @OptIn(ExperimentalKotlinGradlePluginApi::class)
        binaries {
            // Configures a JavaExec task named "runJvm" and a Gradle distribution for the "main"
compilation in this target
            executable {
                mainClass.set("foo.MainKt")
            }

            // Configures a JavaExec task named "runJvmAnother" and a Gradle distribution for the
"main" compilation
            executable(KotlinCompilation.MAIN_COMPILATION_NAME, "another") {
                // Set a different class
                mainClass.set("foo.MainAnotherKt")
            }

            // Configures a JavaExec task named "runJvmTest" and a Gradle distribution for the "test"
compilation
            executable(KotlinCompilation.TEST_COMPILATION_NAME) {
                mainClass.set("foo.MainTestKt")
            }

            // Configures a JavaExec task named "runJvmTestAnother" and a Gradle distribution for the
"test" compilation
            executable(KotlinCompilation.TEST_COMPILATION_NAME, "another") {
                mainClass.set("foo.MainAnotherTestKt")
            }
        }
    }
}
```

In this example, Gradle's Distribution plugin is applied on the first `executable {}` block.

If you run into any issues, report them in our issue tracker or let us know in our public Slack channel.

Kotlin/Native

Support for Xcode 16.3

Starting with Kotlin **2.1.21**, the Kotlin/Native compiler supports Xcode 16.3 – the latest stable version of Xcode. Feel free to update your Xcode and continue working on your Kotlin projects for Apple operating systems.

The 2.1.21 release also fixes the related cinterop issue that caused compilation failures in Kotlin Multiplatform projects.

Experimental

New inlining optimization

Kotlin 2.1.20 introduces a new inlining optimization pass, which comes before the actual code generation phase.

The new inlining pass in the Kotlin/Native compiler should perform better than the standard LLVM inliner and improve the runtime performance of the generated code.

The new inlining pass is currently Experimental. To try it out, use the following compiler option:

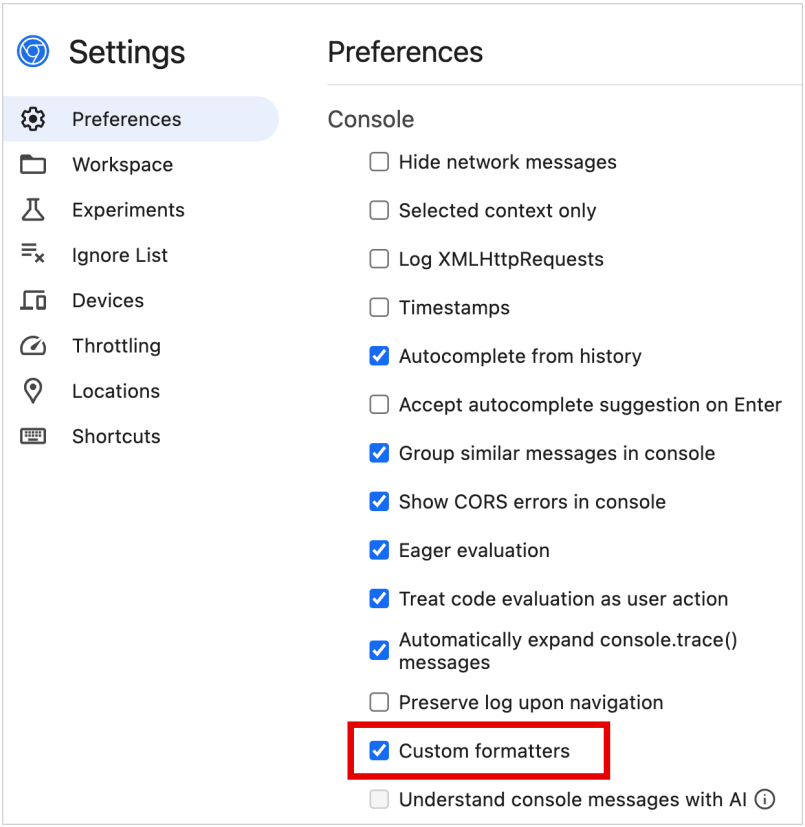
```
-Xbinary=preCodegenInlineThreshold=40
```

Our experiments show that setting the threshold to 40 tokens (code units parsed by the compiler) provides a reasonable compromise for compilation optimization. According to our benchmarks, this gives an overall performance improvement of 9.5%. Of course, you can try out other values, too.

If you experience increased binary size or compilation time, please report such issues via YouTrack.

Kotlin/Wasm

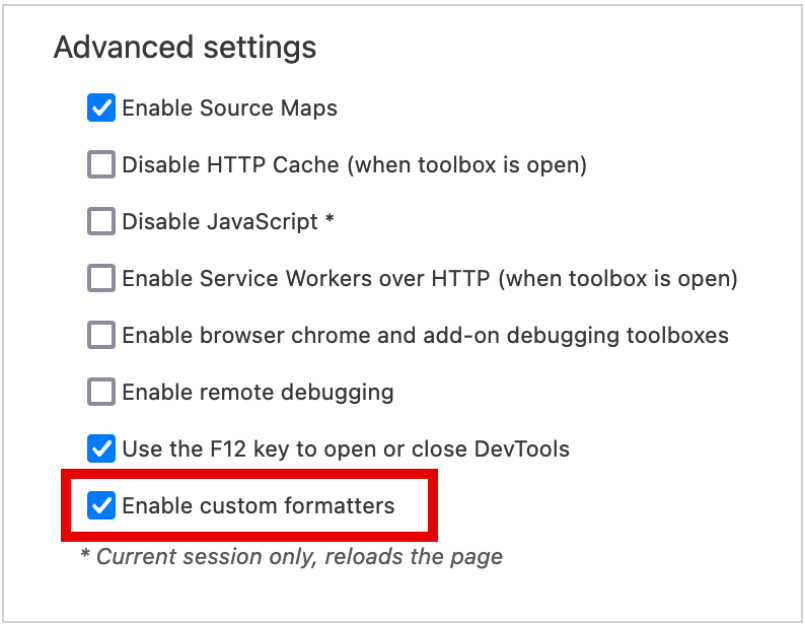
This release improves Kotlin/Wasm debugging and property usage. Custom formatters now work out of the box in development builds, while DWARF debugging facilitates code inspection. Additionally, the Provider API simplifies property usage in Kotlin/Wasm and Kotlin/JS.



Custom formatters enabled by default

Before, you had to manually configure custom formatters to improve debugging in web browsers when working with Kotlin/Wasm code.

In this release, custom formatters are enabled by default in development builds, so you don't need additional Gradle configurations.



To use this feature, you only need to ensure that custom formatters are enabled in your browser's developer tools:

- In Chrome DevTools, find the custom formatters checkbox in **Settings | Preferences | Console**:

Enable custom formatters in Chrome

- In Firefox DevTools, find the custom formatters checkbox in **Settings | Advanced settings**:

Enable custom formatters in Firefox

This change primarily affects Kotlin/Wasm development builds. If you have specific requirements for production builds, you need to adjust your Gradle configuration accordingly. To do so, add the following compiler option to the `wasmJs {}` block:

```
// build.gradle.kts
kotlin {
    wasmJs {
        // ...

        compilerOptions {
            freeCompilerArgs.add("-Xwasm-debugger-custom-formatters")
        }
    }
}
```

Support for DWARF to debug Kotlin/Wasm code

Kotlin 2.1.20 introduces support for DWARF (debugging with arbitrary record format) in Kotlin/Wasm.

With this change, the Kotlin/Wasm compiler is able to embed DWARF data into the generated WebAssembly (Wasm) binary. Many debuggers and virtual machines can read this data to provide insights into the compiled code.

DWARF is mainly useful for debugging Kotlin/Wasm applications inside standalone Wasm virtual machines (VMs). To use this feature, the Wasm VM and debugger must support DWARF.

With DWARF support, you can step through Kotlin/Wasm applications, inspect variables, and gain code insights. To enable this feature, use the following compiler option:

```
-Xwasm-generate-dwarf
```

Migration to Provider API for Kotlin/Wasm and Kotlin/JS properties

Previously, properties in Kotlin/Wasm and Kotlin/JS extensions were mutable (`var`) and assigned directly in build scripts:

```
the<NodeJsExtension>().version = "2.0.0"
```

Now, properties are exposed through the Provider API, and you must use the `.set()` function to assign values:

```
the<NodeJsEnvSpec>().version.set("2.0.0")
```

The Provider API ensures that values are lazily computed and properly integrated with task dependencies, improving build performance.

With this change, direct property assignments are deprecated in favor of `*EnvSpec` classes, such as `NodeJsEnvSpec` and `YarnRootEnvSpec` .

Additionally, several alias tasks have been removed to avoid confusion:

Deprecated task	Replacement
`wasmJsRun`	`wasmJsBrowserDevelopmentRun`
`wasmJsBrowserRun`	`wasmJsBrowserDevelopmentRun`
`wasmJsNodeRun`	`wasmJsNodeDevelopmentRun`

Deprecated task	Replacement
`wasmJsBrowserWebpack`	`wasmJsBrowserProductionWebpack` or `wasmJsBrowserDistribution`
`jsRun`	`jsBrowserDevelopmentRun`
`jsBrowserRun`	`jsBrowserDevelopmentRun`
`jsNodeRun`	`jsNodeDevelopmentRun`
`jsBrowserWebpack`	`jsBrowserProductionWebpack` or `jsBrowserDistribution`

If you only use Kotlin/JS or Kotlin/Wasm in build scripts, no action is required as Gradle automatically handles assignments.

However, if you maintain a plugin based on the Kotlin Gradle Plugin, and your plugin does not apply `kotlin-dsl`, you must update property assignments to use the `.set()` function.

Gradle

Kotlin 2.1.20 is fully compatible with Gradle 7.6.3 through 8.11. You can also use Gradle versions up to the latest Gradle release. However, be aware that doing so may result in deprecation warnings, and some new Gradle features might not work.

This version of Kotlin includes compatibility of Kotlin Gradle plugins with Gradle's Isolated Projects as well as support for custom Gradle publication variants.

Experimental

Kotlin Gradle plugins compatible with Gradle's Isolated Projects

> This feature is currently in a pre-Alpha state in Gradle. JS and Wasm targets are not supported at the moment. Use it only with Gradle version 8.10 or higher and solely for evaluation purposes.

Since Kotlin 2.1.0, you've been able to preview Gradle's Isolated Projects feature in your projects.

Previously, you had to configure the Kotlin Gradle plugin to make your project compatible with the Isolated Projects feature before you could try it out. In Kotlin 2.1.20, this additional step is no longer necessary.

Now, to enable the Isolated Projects feature, you only need to set the system property.

Gradle's Isolated Projects feature is supported in Kotlin Gradle plugins for both multiplatform projects and projects that contain only the JVM or Android target.

Specifically for multiplatform projects, if you notice problems with your Gradle build after upgrading, you can opt out of the new Kotlin Gradle plugin behavior by adding:

```
kotlin.kmp.isolated-projects.support=disable
```

However, if you use this Gradle property in your multiplatform project, you can't use the Isolated Projects feature.

Let us know about your experience with this feature in YouTrack.

Experimental

Support for adding custom Gradle publication variants

Kotlin 2.1.20 introduces support for adding custom Gradle publication variants. This feature is available for multiplatform projects and projects targeting the JVM.

You cannot modify existing Gradle variants with this feature.

This feature is Experimental. To opt in, use the `@OptIn(ExperimentalKotlinGradlePluginApi::class)` annotation.

To add a custom Gradle publication variant, invoke the `adhocSoftwareComponent()` function, which returns an instance of `AdhocComponentWithVariants` that you can configure in the Kotlin DSL:

```
plugins {
    // Only JVM and Multiplatform are supported
    kotlin("jvm")
    // or
    kotlin("multiplatform")
}

kotlin {
    @OptIn(ExperimentalKotlinGradlePluginApi::class)
    publishing {
        // Returns an instance of AdhocSoftwareComponent
        adhocSoftwareComponent()
        // Alternatively, you can configure AdhocSoftwareComponent in the DSL block as follows
        adhocSoftwareComponent {
            // Add your custom variants here using the AdhocSoftwareComponent API
        }
    }
}
```

For more information on variants, see Gradle's Customizing publishing guide.

Standard library

This release brings new Experimental features to the standard library: common atomic types, improved support for UUIDs, and new time-tracking functionality.

Experimental

Common atomic types

In Kotlin 2.1.20, we are introducing common atomic types in the standard library's `kotlin.concurrent.atomics` package, enabling shared, platform-independent code for thread-safe operations. This simplifies development for Kotlin Multiplatform projects by removing the need to duplicate atomic-dependent logic across source sets.

The `kotlin.concurrent.atomics` package and its properties are Experimental. To opt in, use the `@OptIn(ExperimentalAtomicApi::class)` annotation or the compiler option `-opt-in=kotlin.ExperimentalAtomicApi`.

Here's an example that shows how you can use `AtomicInt` to safely count processed items across multiple threads:

```
// Imports the necessary libraries
import kotlin.concurrent.atomics.*
import kotlinx.coroutines.*

@OptIn(ExperimentalAtomicApi::class)
suspend fun main() {
    // Initializes the atomic counter for processed items
    var processedItems = AtomicInt(0)
    val totalItems = 100
    val items = List(totalItems) { "item$it" }
    // Splits the items into chunks for processing by multiple coroutines
    val chunkSize = 20
    val itemChunks = items.chunked(chunkSize)
    coroutineScope {
        for (chunk in itemChunks) {
            launch {
                for (item in chunk) {
                    println("Processing $item in thread ${Thread.currentThread()}")
                    processedItems += 1 // Increment counter atomically
                }
            }
        }
    }
    // Prints the total number of processed items
    println("Total processed items: ${processedItems.load()}")
}
```

To enable seamless interoperability between Kotlin's atomic types and Java's `java.util.concurrent.atomic` atomic types, the API provides the `.asJavaAtomic()` and `.asKotlinAtomic()` extension functions. On the JVM, Kotlin atomics and Java atomics are the same types in runtime, so you can transform Java atomics into Kotlin atomics and vice versa without any overhead.

Here's an example that shows how Kotlin and Java atomic types can work together:

```
// Imports the necessary libraries
import kotlin.concurrent.atomics.*
import java.util.concurrent.atomic.*

@OptIn(ExperimentalAtomicApi::class)
fun main() {
    // Converts Kotlin's AtomicInt to Java's AtomicInteger
    val kotlinAtomic = AtomicInt(42)
    val javaAtomic: AtomicInteger = kotlinAtomic.asJavaAtomic()
    println("Java atomic value: ${javaAtomic.get()}")
    // Java atomic value: 42

    // Converts Java's AtomicInteger back to Kotlin's AtomicInt
    val kotlinAgain: AtomicInt = javaAtomic.asKotlinAtomic()
    println("Kotlin atomic value: ${kotlinAgain.load()}")
    // Kotlin atomic value: 42
}
```

Experimental

Changes in UUID parsing, formatting, and comparability

The JetBrains team continues to improve the support for UUIDs introduced to the standard library in 2.0.20.

Previously, the `parse()` function only accepted UUIDs in the hex-and-dash format. With Kotlin 2.1.20, you can use `parse()` for *both* the hex-and-dash and the plain hexadecimal (without dashes) formats.

We've also introduced functions specific to operations with the hex-and-dash format in this release:

- `parseHexDash()` parses UUIDs from the hex-and-dash format.
- `toHexDashString()` converts a `Uuid` into a `String` in the hex-and-dash format (mirroring the functionality of `toString()`).

These functions work similarly to `parseHex()` and `toHexString()`, which were introduced earlier for the hexadecimal format. Explicit naming for parsing and formatting functionality should improve code clarity and your overall experience with UUIDs.

UUIDs in Kotlin are now `Comparable`. Starting with Kotlin 2.1.20, you can directly compare and sort values of the `Uuid` type. This enables the use of the `<` and `>` operators and standard library extensions available exclusively for `Comparable` types or their collections (such as `sorted()`), and it also allows passing UUIDs to any functions or APIs that require the `Comparable` interface.

Remember that the UUID support in the standard library is still Experimental. To opt in, use the `@OptIn(ExperimentalUuidApi::class)` annotation or the compiler option `-opt-in=kotlin.uuid.ExperimentalUuidApi`:

```
import kotlin.uuid.ExperimentalUuidApi
import kotlin.uuid.Uuid

@OptIn(ExperimentalUuidApi::class)
fun main() {
    // parse() accepts a UUID in a plain hexadecimal format
    val uuid = Uuid.parse("550e8400e29b41d4a716446655440000")

    // Converts it to the hex-and-dash format
    val hexDashFormat = uuid.toHexDashString()

    // Outputs the UUID in the hex-and-dash format
    println(hexDashFormat)

    // Outputs UUIDs in ascending order
    println(
        listOf(
            uuid,
            Uuid.parse("780e8400e29b41d4a716446655440005"),
            Uuid.parse("5ab88400e29b41d4a716446655440076")
        ).sorted()
    )
}
```

Experimental

New time tracking functionality

Starting with Kotlin 2.1.20, the standard library provides the ability to represent a moment in time. This functionality was previously only available in `kotlinx-datetime`, an official Kotlin library.

The `kotlinx.datetime.Clock` interface is introduced to the standard library as `kotlin.time.Clock` and the `kotlinx.datetime.Instant` class as `kotlin.time.Instant`. These concepts naturally align with the `time` package in the standard library because they're only concerned with moments in time compared to a more complex calendar and timezone functionality that remains in `kotlinx-datetime`.

`Instant` and `Clock` are useful when you need precise time tracking without considering time zones or dates. For example, you can use them to log events with timestamps, measure durations between two points in time, and obtain the current moment for system processes.

To provide interoperability with other languages, additional converter functions are available:

- `.toKotlinInstant()` converts a time value to a `kotlin.time.Instant` instance.
- `.toJavaInstant()` converts the `kotlin.time.Instant` value to a `java.time.Instant` value.
- `Instant.toJSDate()` converts the `kotlin.time.Instant` value to an instance of the JS `Date` class. This conversion is not precise; JS uses millisecond precision to represent dates, while Kotlin allows for nanosecond resolution.

The new time features of the standard library are still Experimental. To opt in, use the `@OptIn(ExperimentalTime::class)` annotation:

```
import kotlin.time.*

@OptIn(ExperimentalTime::class)
fun main() {

    // Get the current moment in time
    val currentInstant = Clock.System.now()
    println("Current time: $currentInstant")

    // Find the difference between two moments in time
    val pastInstant = Instant.parse("2023-01-01T00:00:00Z")
    val duration = currentInstant - pastInstant

    println("Time elapsed since 2023-01-01: $duration")
}
```

For more information on the implementation, see this KEEP proposal.

Compose compiler

In 2.1.20, the Compose compiler relaxes some restrictions on `@Composable` functions introduced in previous releases. In addition, the Compose compiler Gradle plugin is set to include source information by default, aligning the behavior on all platforms with Android.

Support for parameters with default values in open `@Composable` functions

The compiler previously restricted parameters with default values in open `@Composable` functions due to incorrect compiler output, which would result in crashes at runtime. The underlying issue is now resolved, and parameters with default values are fully supported when used with Kotlin 2.1.20 or newer.

Compose compiler allowed parameters with default values in open functions before version 1.5.8, so the support depends on project configuration:

- If an open composable function is compiled with Kotlin version 2.1.20 or newer, the compiler generates correct wrappers for parameters with default values. This includes wrappers compatible with pre-1.5.8 binaries, meaning that downstream libraries will also be able to use this open function.
- If the open composable function is compiled with Kotlin older than 2.1.20, Compose uses a compatibility mode, which might result in runtime crashes. When using the compatibility mode, the compiler emits a warning to highlight potential problems.

Final overridden functions are allowed to be restartable

Virtual functions (overrides of `open` and `abstract`, including interfaces) were forced to be non-restartable with the 2.1.0 release. This restriction is now relaxed for functions that are members of final classes or are `final` themselves – they will be restarted or skipped as usual.

You might observe some behavior changes in affected functions after upgrading to Kotlin 2.1.20. To force non-restartable logic from the previous version, apply the `@NonRestartableComposable` annotation to the function.

`ComposableSingletons` removed from public API

`ComposableSingletons` is a class created by the Compose compiler when optimizing `@Composable` lambdas. Lambdas that do not capture any parameters are allocated once and cached in a property of the class, saving allocations during runtime. The class is generated with internal visibility and is only intended for optimizing lambdas inside a compilation unit (usually a file).

However, this optimization was also applied to `inline` function bodies, which resulted in singleton lambda instances leaking into the public API. To fix this problem, starting with 2.1.20, `@Composable` lambdas are no longer optimized into singletons inside inline functions. At the same time, the Compose compiler will continue generating singleton classes and lambdas for inline functions to support binary compatibility for modules that were compiled under the previous model.

Source information included by default

The Compose compiler Gradle plugin already has the including source information feature enabled by default on Android. Starting with Kotlin 2.1.20, this feature will be enabled by default on all platforms.

Remember to check if you set this option using `freeCompilerArgs`. This method can cause the build to fail when used alongside the plugin, due to an option being effectively set twice.

Breaking changes and deprecations

- To align Kotlin Multiplatform with upcoming changes in Gradle, we are phasing out the `withJava()` function. Java source sets are now created by default. If you use the Java test fixtures Gradle plugin, upgrade directly to Kotlin 2.1.21 to avoid compatibility issues.
- The JetBrains team is proceeding with the deprecation of the `kotlin-android-extensions` plugin. If you try to use it in your project, you'll now get a configuration error, and no plugin code will be executed.
- The legacy `kotlin.incremental.classpath.snapshot.enabled` property has been removed from the Kotlin Gradle plugin. The property used to provide an opportunity to fall back to a built-in ABI snapshot on the JVM. The plugin now uses other methods to detect and avoid unnecessary recompilations, making the property obsolete.

Documentation updates

The Kotlin documentation has received some notable changes:

Revamped and new pages

- Kotlin roadmap – see the updated list of Kotlin's priorities on language and ecosystem evolution.

- Gradle best practices page – learn essential best practices for optimizing your Gradle builds and improving performance.
- Compose Multiplatform and Jetpack Compose – an overview of the relation between the two UI frameworks.
- Kotlin Multiplatform and Flutter – see the comparison of two popular cross-platform frameworks.
- Interoperability with C – explore the details of Kotlin's interoperability with C.
- Numbers – learn about different Kotlin types for representing numbers.

New and updated tutorials

- Publish your library to Maven Central – learn how to publish KMP library artifacts to the most popular Maven repository.
- Kotlin/Native as a dynamic library – create a dynamic Kotlin library.
- Kotlin/Native as an Apple framework – create your own framework and use Kotlin/Native code from Swift/Objective-C applications on macOS and iOS.

How to update to Kotlin 2.1.20

Starting from IntelliJ IDEA 2023.3 and Android Studio Iguana (2023.2.1) Canary 15, the Kotlin plugin is distributed as a bundled plugin included in your IDE. This means that you can't install the plugin from JetBrains Marketplace anymore.

To update to the new Kotlin version, change the Kotlin version to 2.1.20 in your build scripts.

What's new in Kotlin 2.1.0

Released: November 27, 2024

The Kotlin 2.1.0 release is here! Here are the main highlights:

- **New language features in preview**: Guard conditions in `when` with a subject, non-local `break` and `continue`, and multi-dollar string interpolation.
- **K2 compiler updates**: More flexibility around compiler checks and improvements to the kapt implementation.
- **Kotlin Multiplatform**: Introduced basic support for Swift export, stable Gradle DSL for compiler options, and more.
- **Kotlin/Native**: Improved support for `iosArm64` and other updates.
- **Kotlin/Wasm**: Multiple updates, including support for incremental compilation.
- **Gradle support**: Improved compatibility with newer versions of Gradle and the Android Gradle plugin, along with updates to the Kotlin Gradle plugin API.
- **Documentation**: Significant improvements to the Kotlin documentation.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 2.1.0 are bundled in the latest IntelliJ IDEA and Android Studio. You don't need to update the Kotlin plugin in your IDE. All you need to do is change the Kotlin version to 2.1.0 in your build scripts.

See Update to a new Kotlin version for details.

Language

After the Kotlin 2.0.0 release with the K2 compiler, the JetBrains team is focusing on improving the language with new features. In this release, we are excited to announce several new language design improvements.

These features are available in preview, and we encourage you to try them and share your feedback:

- Guard conditions in `when` with a subject
- Non-local `break` and `continue`
- Multi-dollar interpolation: improved handling of `$` in string literals

> All the features have IDE support in the latest 2024.3 version of IntelliJ IDEA with K2 mode enabled.
>
> Learn more in the IntelliJ IDEA 2024.3 blog post.

See the full list of Kotlin language design features and proposals.

This release also brings the following language updates:

- Support for requiring opt-in to extend APIs
- Improved overload resolution for functions with generic types
- Improved exhaustiveness checks for when expressions with sealed classes

Guard conditions in when with a subject

> This feature is In preview, and opt-in is required (see details below).
>
> We would appreciate your feedback in YouTrack.

Starting from 2.1.0, you can use guard conditions in `when` expressions or statements with subjects.

Guard conditions allow you to include more than one condition for the branches of a `when` expression, making complex control flows more explicit and concise as well as flattening the code structure.

To include a guard condition in a branch, place it after the primary condition, separated by `if`:

```
sealed interface Animal {
    data class Cat(val mouseHunter: Boolean) : Animal {
        fun feedCat() {}
    }

    data class Dog(val breed: String) : Animal {
        fun feedDog() {}
    }
}

fun feedAnimal(animal: Animal) {
    when (animal) {
        // Branch with only the primary condition. Calls `feedDog()` when `animal` is `Dog`
        is Animal.Dog -> animal.feedDog()
        // Branch with both primary and guard conditions. Calls `feedCat()` when `animal` is `Cat` and
is not `mouseHunter`
        is Animal.Cat if !animal.mouseHunter -> animal.feedCat()
        // Prints "Unknown animal" if none of the above conditions match
        else -> println("Unknown animal")
    }
}
```

In a single `when` expression, you can combine branches with and without guard conditions. The code in a branch with a guard condition runs only if both the primary condition and the guard condition are `true`. If the primary condition does not match, the guard condition is not evaluated. Additionally, guard conditions support `else if`.

To enable guard conditions in your project, use the following compiler option in the command line:

```
kotlinc -Xwhen-guards main.kt
```

Or add it to the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xwhen-guards")
    }
}
```

Non-local break and continue

> This feature is In preview, and opt-in is required (see details below).
>
> We would appreciate your feedback in YouTrack.

Kotlin 2.1.0 adds a preview of another long-awaited feature, the ability to use non-local `break` and `continue`. This feature expands the toolset you can use in the scope of inline functions and reduces boilerplate code in your project.

Previously, you could use only non-local returns. Now, Kotlin also supports `break` and `continue` jump expressions non-locally. This means that you can apply them within lambdas passed as arguments to an inline function that encloses the loop:

```
fun processList(elements: List<Int>): Boolean {
    for (element in elements) {
        val variable = element.nullableMethod() ?: run {
            log.warning("Element is null or invalid, continuing...")
            continue
        }
        if (variable == 0) return true // If variable is zero, return true
    }
    return false
}
```

To try the feature in your project, use the `-Xnon-local-break-continue` compiler option in the command line:

```
kotlinc -Xnon-local-break-continue main.kt
```

Or add it in the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xnon-local-break-continue")
    }
}
```

We're planning to make this feature Stable in future Kotlin releases. If you encounter any issues when using non-local `break` and `continue`, please report them to our issue tracker.

Multi-dollar string interpolation

> The feature is In preview and opt-in is required (see details below).
>
> We would appreciate your feedback in YouTrack.

Kotlin 2.1.0 introduces support for multi-dollar string interpolation, improving how the dollar sign (`$`) is handled within string literals. This feature is helpful in contexts that require multiple dollar signs, such as templating engines, JSON schemas, or other data formats.

String interpolation in Kotlin uses a single dollar sign. However, using a literal dollar sign in a string, which is common in financial data and templating systems, required workarounds such as `${'$'}`. With the multi-dollar interpolation feature enabled, you can configure how many dollar signs trigger interpolation, with fewer dollar signs being treated as string literals.

Here's an example of how to generate an JSON schema multi-line string with placeholders using `$` :

```
val KClass<*>.jsonSchema : String
    get() = $$"""
    {
      "$schema": "https://json-schema.org/draft/2020-12/schema",
      "$id": "https://example.com/product.schema.json",
      "$dynamicAnchor": "meta"
      "title": "$${simpleName ?: qualifiedName ?: "unknown"}",
      "type": "object"
    }
    """
```

In this example, the initial `$$` means that you need **two dollar signs** (`$$`) to trigger interpolation. It prevents `$schema` , `$id` , and `$dynamicAnchor` from being interpreted as interpolation markers.

This approach is especially helpful when working with systems that use dollar signs for placeholder syntax.

To enable the feature, use the following compiler option in the command line:

```
kotlinc -Xmulti-dollar-interpolation main.kt
```

Alternatively, update the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.add("-Xmulti-dollar-interpolation")
    }
}
```

If your code already uses standard string interpolation with a single dollar sign, no changes are needed. You can use `$$` whenever you need literal dollar signs in your strings.

Support for requiring opt-in to extend APIs

Kotlin 2.1.0 introduces the `@SubclassOptInRequired` annotation, which allows library authors to require an explicit opt-in before users can implement experimental interfaces or extend experimental classes.

This feature can be useful when a library API is stable enough to use but might evolve with new abstract functions, making it unstable for inheritance.

To add the opt-in requirement to an API element, use the `@SubclassOptInRequired` annotation with a reference to the annotation class:

```
@RequiresOptIn(
level = RequiresOptIn.Level.WARNING,
message = "Interfaces in this library are experimental"
)
annotation class UnstableApi()

@SubclassOptInRequired(UnstableApi::class)
interface CoreLibraryApi
```

In this example, the `CoreLibraryApi` interface requires users to opt in before they can implement it. A user can opt in like this:

```
@OptIn(UnstableApi::class)
interface MyImplementation: CoreLibraryApi
```

> When you use the `@SubclassOptInRequired` annotation to require opt-in, the requirement is not propagated to any inner or nested classes.

For a real-world example of how to use the `@SubclassOptInRequired` annotation in your API, check out the `SharedFlow` interface in the `kotlinx.coroutines` library.

Improved overload resolution for functions with generic types

Previously, if you had a number of overloads for a function where some had value parameters of a generic type and others had function types in the same position, the resolution behavior could sometimes be inconsistent.

This led to different behavior depending on whether your overloads were member functions or extension functions. For example:

```
class KeyValueStore<K, V> {
    fun store(key: K, value: V) {} // 1
    fun store(key: K, lazyValue: () -> V) {} // 2
}

fun <K, V> KeyValueStore<K, V>.storeExtension(key: K, value: V) {} // 1
fun <K, V> KeyValueStore<K, V>.storeExtension(key: K, lazyValue: () -> V) {} // 2

fun test(kvs: KeyValueStore<String, Int>) {
    // Member functions
    kvs.store("", 1)    // Resolves to 1
    kvs.store("") { 1 } // Resolves to 2

    // Extension functions
    kvs.storeExtension("", 1)    // Resolves to 1
    kvs.storeExtension("") { 1 } // Doesn't resolve
}
```

In this example, the `KeyValueStore` class has two overloads for the `store()` function, where one overload has function parameters with generic types `K` and `V`, and another has a lambda function that returns a generic type `V`. Similarly, there are two overloads for the extension function: `storeExtension()`.

When the `store()` function was called with and without a lambda function, the compiler successfully resolved the correct overloads. However, when the extension function `storeExtension()` was called with a lambda function, the compiler didn't resolve the correct overload because it incorrectly considered both overloads to be applicable.

To fix this problem, we've introduced a new heuristic so that the compiler can discard a possible overload when a function parameter with a generic type can't accept a lambda function based on information from a different argument. This change makes the behavior of member functions and extension functions consistent, and it is enabled by default in Kotlin 2.1.0.

Improved exhaustiveness checks for when expressions with sealed classes

In previous versions of Kotlin, the compiler required an `else` branch in `when` expressions for type parameters with sealed upper bounds, even when all cases in the `sealed class` hierarchy were covered. This behavior is addressed and improved in Kotlin 2.1.0, making exhaustiveness checks more powerful and allowing you to remove redundant `else` branches, keeping `when` expressions cleaner and more intuitive.

Here's an example demonstrating the change:

```
sealed class Result
object Error: Result()
class Success(val value: String): Result()

fun <T : Result> render(result: T) = when (result) {
    Error -> "Error!"
    is Success -> result.value
    // Requires no else branch
}
```

Kotlin K2 compiler

With Kotlin 2.1.0, the K2 compiler now provides more flexibility when working with compiler checks and warnings, as well as improved support for the kapt plugin.

Extra compiler checks

With Kotlin 2.1.0, you can now enable additional checks in the K2 compiler. These are extra declaration, expression, and type checks that are usually not crucial for compilation but can still be useful if you want to validate the following cases:

Check type	Comment
`REDUNDANT_NULLABLE`	`Boolean??` is used instead of `Boolean?`
`PLATFORM_CLASS_MAPPED_TO_KOTLIN`	`java.lang.String` is used instead of `kotlin.String`
`ARRAY_EQUALITY_OPERATOR_CAN_BE_REPLACED_WITH_EQUALS`	`arrayOf("") == arrayOf("")` is used instead of `arrayOf("").contentEquals(arrayOf(""))`
`REDUNDANT_CALL_OF_CONVERSION_METHOD`	`42.toInt()` is used instead of `42`
`USELESS_CALL_ON_NOT_NULL`	`"".orEmpty()` is used instead of `""`
`REDUNDANT_SINGLE_EXPRESSION_STRING_TEMPLATE`	`"$string"` is used instead of `string`
`UNUSED_ANONYMOUS_PARAMETER`	A parameter is passed in the lambda expression but never used
`REDUNDANT_VISIBILITY_MODIFIER`	`public class Klass` is used instead of `class Klass`
`REDUNDANT_MODALITY_MODIFIER`	`final class Klass` is used instead of `class Klass`
`REDUNDANT_SETTER_PARAMETER_TYPE`	`set(value: Int)` is used instead of `set(value)`
`CAN_BE_VAL`	`var local = 0` is defined but never reassigned, can be `val local = 42` instead
`ASSIGNED_VALUE_IS_NEVER_READ`	`val local = 42` is defined but never used afterward in the code
`UNUSED_VARIABLE`	`val local = 0` is defined but never used in the code
`REDUNDANT_RETURN_UNIT_TYPE`	`fun foo(): Unit {}` is used instead of `fun foo() {}`
`UNREACHABLE_CODE`	Code statement is present but can never be executed

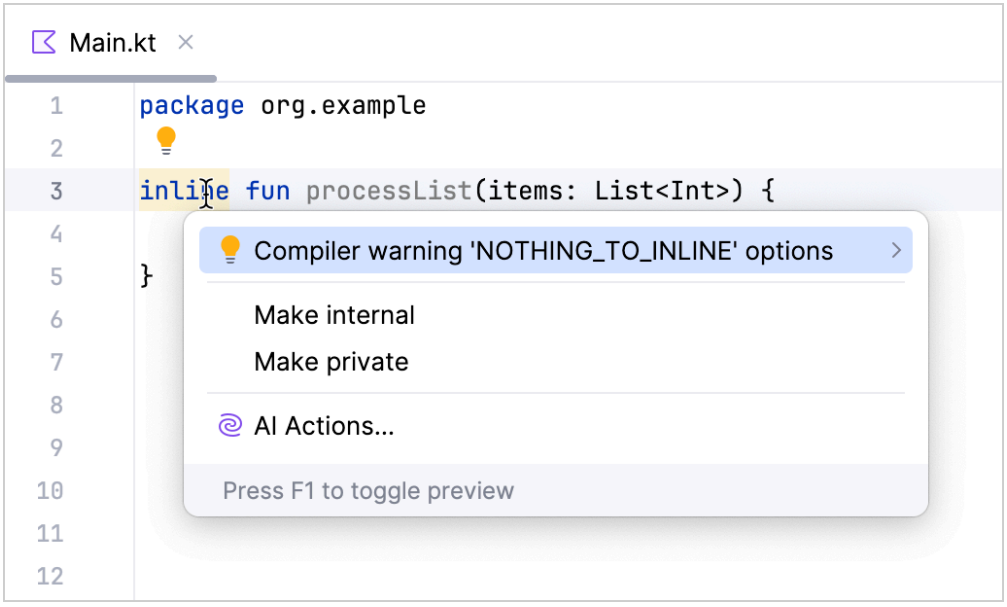
If the check is true, you'll receive a compiler warning with a suggestion on how to fix the problem.

Extra checks are disabled by default. To enable them, use the `-Wextra` compiler option in the command line or specify `extraWarnings` in the `compilerOptions {}` block of your Gradle build file:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        extraWarnings.set(true)
    }
}
```

For more information on how to define and use compiler options, see Compiler options in the Kotlin Gradle plugin.

Global warning suppression



In 2.1.0, the Kotlin compiler has received a highly requested feature – the ability to suppress warnings globally.

You can now suppress specific warnings in the whole project by using the `-Xsuppress-warning=WARNING_NAME` syntax in the command line or the `freeCompilerArgs` attribute in the `compilerOptions {}` block of your build file.

For example, if you have extra compiler checks enabled in your project but want to suppress one of them, use:

```
// build.gradle.kts
kotlin {
    compilerOptions {
        extraWarnings.set(true)
        freeCompilerArgs.add("-Xsuppress-warning=CAN_BE_VAL")
    }
}
```

If you want to suppress a warning but don't know its name, select the element and click the light bulb icon (or use Cmd + Enter/Alt + Enter):

Warning name intention

The new compiler option is currently Experimental. The following details are also worth noting:

- Error suppression is not allowed.

- If you pass an unknown warning name, compilation will result in an error.
- You can specify several warnings at once:

Command line

```
kotlinc -Xsuppress-warning=NOTHING_TO_INLINE -Xsuppress-warning=NO_TAIL_CALLS_FOUND main.kt
```

Build file

```
// build.gradle.kts
kotlin {
    compilerOptions {
        freeCompilerArgs.addAll(
            listOf(
                "-Xsuppress-warning=NOTHING_TO_INLINE",
                "-Xsuppress-warning=NO_TAIL_CALLS_FOUND"
            )
        )
    }
}
```

Improved K2 kapt implementation

The kapt plugin for the K2 compiler (K2 kapt) is in Alpha. It may be changed at any time.

We would appreciate your feedback in YouTrack.

Currently, projects using the kapt plugin work with the K1 compiler by default, supporting Kotlin versions up to 1.9.

In Kotlin 1.9.20, we launched an experimental implementation of the kapt plugin with the K2 compiler (K2 kapt). We have now improved K2 kapt's internal implementation to mitigate technical and performance issues.

While the new K2 kapt implementation doesn't introduce new features, its performance has significantly improved compared to the previous K2 kapt implementation. Additionally, the K2 kapt plugin's behavior is now much closer to that of K1 kapt.

To use the new K2 kapt plugin implementation, enable it just like you did the previous K2 kapt plugin. Add the following option to the `gradle.properties` file of your project:

```
kapt.use.k2=true
```

In upcoming releases, the K2 kapt implementation will be enabled by default instead of K1 kapt, so you will no longer need to enable it manually.

We highly appreciate your feedback before the new implementation is stabilized.

Resolution for overload conflicts between unsigned and non-primitive types

This release addresses the issue of resolution for overload conflicts that could occur in previous versions when functions were overloaded for unsigned and non-primitive types, as in the following examples:

Overloaded extension functions

```
fun Any.doStuff() = "Any"
fun UByte.doStuff() = "UByte"

fun main() {
    val uByte: UByte = UByte.MIN_VALUE
    uByte.doStuff() // Overload resolution ambiguity before Kotlin 2.1.0
}
```

In earlier versions, calling `uByte.doStuff()` led to ambiguity because both the `Any` and `UByte` extensions were applicable.

Overloaded top-level functions

```
fun doStuff(value: Any) = "Any"
fun doStuff(value: UByte) = "UByte"

fun main() {
    val uByte: UByte = UByte.MIN_VALUE
    doStuff(uByte) // Overload resolution ambiguity before Kotlin 2.1.0
}
```

Similarly, the call to `doStuff(uByte)` was ambiguous because the compiler couldn't decide whether to use the `Any` or `UByte` version. With 2.1.0, the compiler now handles these cases correctly, resolving the ambiguity by giving precedence to the more specific type, in this case `UByte`.

Kotlin/JVM

Starting with version 2.1.0, the compiler can generate classes containing Java 23 bytecode.

Change of JSpecify nullability mismatch diagnostics severity to strict

Kotlin 2.1.0 enforces strict handling of nullability annotations from `org.jspecify.annotations`, improving type safety for Java interoperability.

The following nullability annotations are affected:

- `org.jspecify.annotations.Nullable`
- `org.jspecify.annotations.NonNull`
- `org.jspecify.annotations.NullMarked`
- Legacy annotations in `org.jspecify.nullness` (JSpecify 0.2 and earlier)

Starting from Kotlin 2.1.0, nullability mismatches are raised from warnings to errors by default. This ensures that annotations like `@NonNull` and `@Nullable` are enforced during type checks, preventing unexpected nullability issues at runtime.

The `@NullMarked` annotation also affects the nullability of all members within its scope, making the behavior more predictable when you're working with annotated Java code.

Here's an example demonstrating the new default behavior:

```java
// Java
import org.jspecify.annotations.*;
public class SomeJavaClass {
    @NonNull
    public String foo() { // ...
    }

    @Nullable
    public String bar() { // ...
    }
}
```

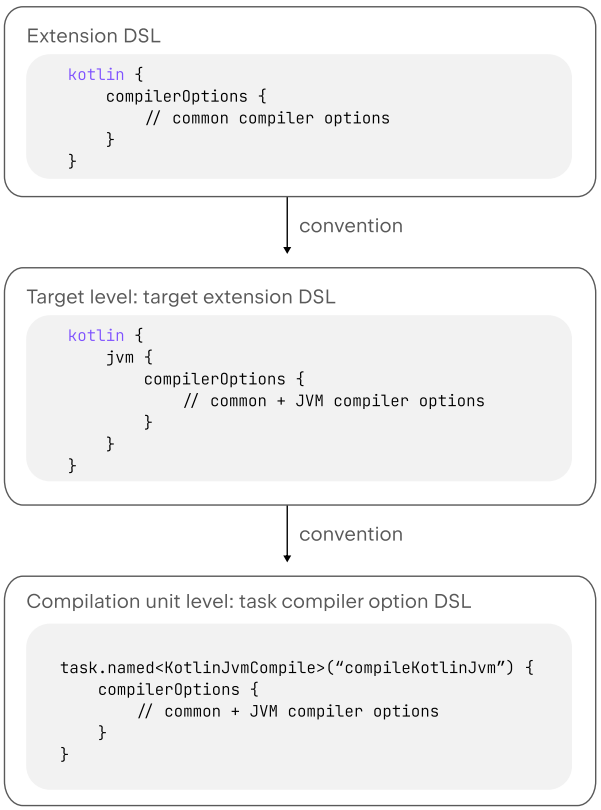
```kotlin
// Kotlin
fun test(sjc: SomeJavaClass) {
    // Accesses a non-null result, which is allowed
    sjc.foo().length

    // Raises an error in the default strict mode because the result is nullable
    // To avoid the error, use ?.length instead
    sjc.bar().length
}
```

You can manually control the severity of diagnostics for these annotations. To do so, use the `-Xnullability-annotations` compiler option to choose a mode:

- `ignore` : Ignore nullability mismatches.
- `warning` : Report warnings for nullability mismatches.
- `strict` : Report errors for nullability mismatches (default mode).

For more information, see Nullability annotations.



Kotlin Multiplatform

Kotlin 2.1.0 introduces basic support for Swift export and makes publishing Kotlin Multiplatform libraries easier. It also focuses on improvements around Gradle that stabilize the new DSL for configuring compiler options and bring a preview of the Isolated Projects feature.

New Gradle DSL for compiler options in multiplatform projects promoted to Stable

In Kotlin 2.0.0, we introduced a new Experimental Gradle DSL to simplify the configuration of compiler options across your multiplatform projects. In Kotlin 2.1.0, this DSL has been promoted to Stable.

The overall project configuration now has three layers. The highest is the extension level, then the target level, and the lowest is the compilation unit (which is usually a compilation task):

Kotlin compiler options levels

To learn more about the different levels and how compiler options can be configured between them, see Compiler options.

Preview Gradle's Isolated Projects in Kotlin Multiplatform

This feature is Experimental and is currently in a pre-Alpha state in Gradle. Use it only with Gradle version 8.10 and solely for evaluation purposes. The feature may be dropped or changed at any time.

We would appreciate your feedback on it in YouTrack. Opt-in is required (see details below).

In Kotlin 2.1.0, you can preview Gradle's Isolated Projects feature in your multiplatform projects.

The Isolated Projects feature in Gradle improves build performance by "isolating" configuration of individual Gradle projects from each other. Each project's build logic is restricted from directly accessing the mutable state of other projects, allowing them to safely run in parallel. To support this feature, we made some changes to the Kotlin Gradle plugin's model, and we are interested in hearing about your experiences during this preview phase.

There are two ways to enable the Kotlin Gradle plugin's new model:

- Option 1: **Testing compatibility without enabling Isolated Projects** – To check compatibility with the Kotlin Gradle plugin's new model without enabling the Isolated Projects feature, add the following Gradle property in the `gradle.properties` file of your project:

```
# gradle.properties
kotlin.kmp.isolated-projects.support=enable
```

- Option 2: **Testing with Isolated Projects enabled** – Enabling the Isolated Projects feature in Gradle automatically configures the Kotlin Gradle plugin to use the new model. To enable the Isolated Projects feature, set the system property. In this case, you don't need to add the Gradle property for the Kotlin Gradle plugin to your project.

Basic support for Swift export

> This feature is currently in the early stages of development. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Version 2.1.0 takes the first step towards providing support for Swift export in Kotlin, allowing you to export Kotlin sources directly to the Swift interface without using Objective-C headers. This should make multiplatform development for Apple targets easier.

The current basic support includes the ability to:

- Export multiple Gradle modules from Kotlin directly to Swift.
- Define custom Swift module names with the `moduleName` property.
- Set collapse rules for the package structure with the `flattenPackage` property.

You can use the following build file in your project as a starting point for setting up Swift export:

```
// build.gradle.kts
kotlin {

    iosX64()
    iosArm64()
    iosSimulatorArm64()

    @OptIn(ExperimentalSwiftExportDsl::class)
    swiftExport {
        // Root module name
        moduleName = "Shared"

        // Collapse rule
        // Removes package prefix from generated Swift code
        flattenPackage = "com.example.sandbox"

        // Export external modules
        export(project(":subproject")) {
            // Exported module name
            moduleName = "Subproject"
            // Collapse exported dependency rule
            flattenPackage = "com.subproject.library"
        }
    }
}
```

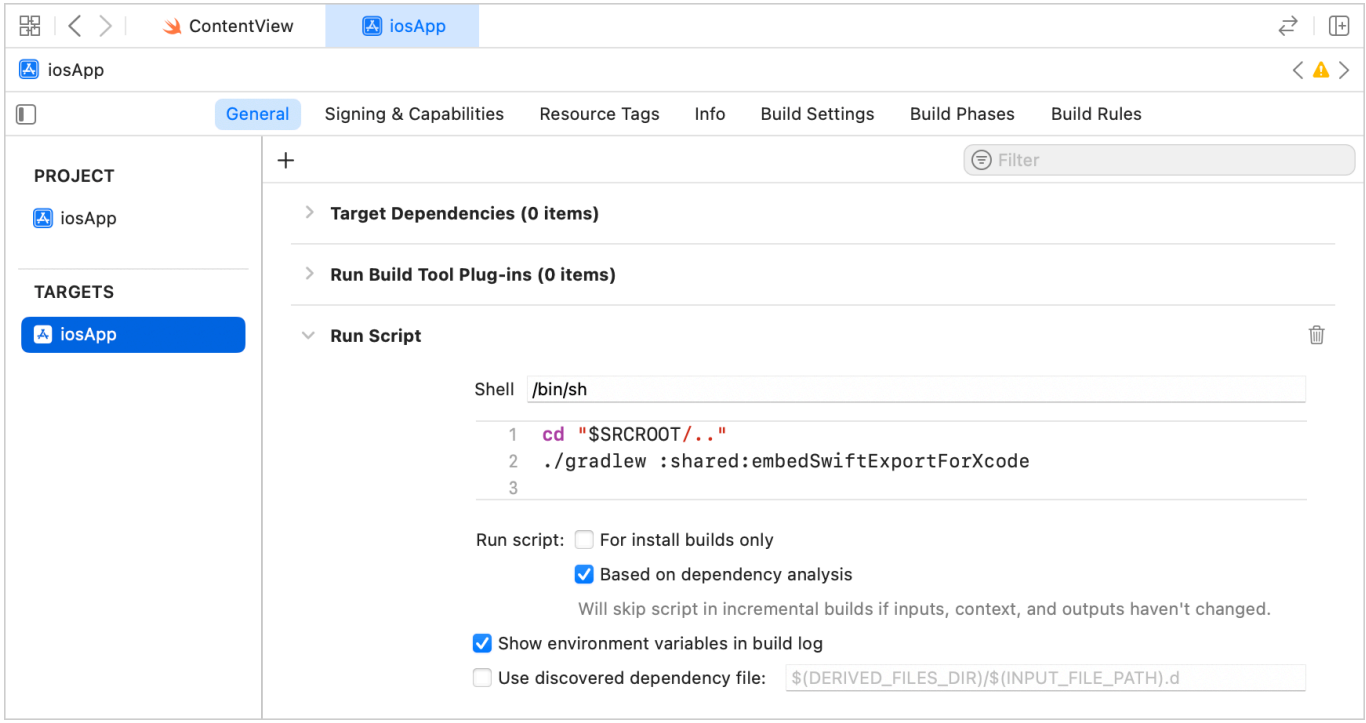
You can also clone our public sample with Swift export already set up.

The compiler automatically generates all the necessary files (including `swiftmodule` files, static `a` library, and header and `modulemap` files) and copies them into the app's build directory, which you can access from Xcode.

How to enable Swift export

Keep in mind that the feature is currently only in the early stages of development.

Swift export currently works in projects that use direct integration to connect the iOS framework to the Xcode project. This is a standard configuration for Kotlin Multiplatform projects created in Android Studio or through the web wizard.



To try out Swift export in your project:

1. Add the following Gradle option to your `gradle.properties` file:

```
# gradle.properties
kotlin.experimental.swift-export.enabled=true
```

2. In Xcode, open the project settings.
3. On the **Build Phases** tab, locate the **Run Script** phase with the `embedAndSignAppleFrameworkForXcode` task.
4. Adjust the script to feature the `embedSwiftExportForXcode` task instead in the run script phase:

```
./gradlew :<Shared module name>:embedSwiftExportForXcode
```

Add the Swift export script

Leave feedback on Swift export

We're planning to expand and stabilize Swift export support in future Kotlin releases. Please leave your feedback in this YouTrack issue.

Ability to publish Kotlin libraries from any host

> This feature is currently Experimental. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

The Kotlin compiler produces `.klib` artifacts for publishing Kotlin libraries. Previously, you could get the necessary artifacts from any host, except for Apple platform targets that required a Mac machine. That put a special restraint on Kotlin Multiplatform projects that targeted iOS, macOS, tvOS, and watchOS targets.

Kotlin 2.1.0 lifts this restriction, adding support for cross-compilation. Now you can use any supported host to produce `.klib` artifacts, which should greatly simplify the publishing process for Kotlin and Kotlin Multiplatform libraries.

How to enable publishing libraries from any host

To try cross-compilation out in your project, add the following binary option to your `gradle.properties` file:

```
# gradle.properties
kotlin.native.enableKlibsCrossCompilation=true
```

This feature is currently Experimental and has some limitations. You still need to use a Mac machine if:

- Your library has a cinterop dependency.
- You have CocoaPods integration set up in your project.
- You need to build or test final binaries for Apple targets.

Leave feedback on publishing libraries from any host

We're planning to stabilize this feature and further improve library publication in future Kotlin releases. Please leave your feedback in our issue tracker YouTrack.

For more information, see Publishing multiplatform libraries.

Support for non-packed klibs

Kotlin 2.1.0 makes it possible to generate non-packed `.klib` file artifacts. This gives you the option to configure dependencies on klibs directly rather than unpack them first.

This change can also improve performance, decreasing compilation and linking time in your Kotlin/Wasm, Kotlin/JS, and Kotlin/Native projects.

For example, our benchmark shows a performance improvement of roughly 3% in total build time on the project with 1 linking and 10 compilation tasks (the project builds a single native executable binary that depends on 9 simplified projects). However, the actual impact on build time depends on both the number of subprojects and their respective sizes.

How to set up your project

By default, Kotlin compilation and linking tasks are now configured to use the new non-packed artifacts.

If you have set up custom build logic for resolving klibs and want to use the new unpacked artifacts, you need to explicitly specify the preferred variant of klib package resolution in your Gradle build file:

```
// build.gradle.kts
import org.jetbrains.kotlin.gradle.plugin.attributes.KlibPackaging
// ...
val resolvableConfiguration = configurations.resolvable("resolvable") {

    // For the new non-packed configuration:
    attributes.attribute(KlibPackaging.ATTRIBUTE, project.objects.named(KlibPackaging.NON_PACKED))

    // For the previous packed configuration:
    attributes.attribute(KlibPackaging.ATTRIBUTE, project.objects.named(KlibPackaging.PACKED))
}
```

Non-packed `.klib` files are generated at the same path in your project's build directory as the packed ones previously were. In turn, packed klibs are now located in the `build/libs` directory.

If no attribute is specified, the packed variant is used. You can check the list of available attributes and variants with the following console command:

```
./gradlew outgoingVariants
```

We would appreciate your feedback on this feature in YouTrack.

Further deprecation of old `android` target

In Kotlin 2.1.0, the deprecation warning for the old `android` target name has been raised to an error.

Currently, we recommend using the `androidTarget` option in your Kotlin Multiplatform projects targeting Android. This is a temporary solution that is necessary to free the `android` name for the upcoming Android/KMP plugin from Google.

We'll provide further migration instructions when the new plugin is available. The new DSL from Google will be the preferred option for Android target support in Kotlin Multiplatform.

For more information, see the Kotlin Multiplatform compatibility guide.

Dropped support for declaring multiple targets of the same type

Before Kotlin 2.1.0, you could declare multiple targets of the same type in your multiplatform projects. However, this made it challenging to distinguish between targets and to support shared source sets effectively. In most cases, a simpler setup, such as using separate Gradle projects, works better. For detailed guidance and an example of how to migrate, see Declaring several similar targets in the Kotlin Multiplatform compatibility guide.

Kotlin 1.9.20 triggered a deprecation warning if you declared multiple targets of the same type in your multiplatform projects. In Kotlin 2.1.0, this deprecation warning is now an error for all targets except Kotlin/JS ones. To learn more about why Kotlin/JS targets are exempt, see this issue in YouTrack.

Kotlin/Native

Kotlin 2.1.0 includes an upgrade for the `iosArm64` target support, improved cinterop caching process, and other updates.

iosArm64 promoted to Tier 1

The `iosArm64` target, which is crucial for Kotlin Multiplatform development, has been promoted to Tier 1. This is the highest level of support in the Kotlin/Native compiler.

This means the target is regularly tested on the CI pipeline to ensure that it's able to compile and run. We also provide source and binary compatibility between compiler releases for the target.

For more information on target tiers, see Kotlin/Native target support.

LLVM update from 11.1.0 to 16.0.0

In Kotlin 2.1.0, we updated LLVM from version 11.1.0 to 16.0.0. The new version includes bug fixes and security updates. In certain cases, it also provides compiler optimizations and faster compilation.

If you have Linux targets in your project, take note that the Kotlin/Native compiler now uses the `lld` linker by default for all Linux targets.

This update shouldn't affect your code, but if you encounter any issues, please report them to our issue tracker.

Changes to caching in cinterop

In Kotlin 2.1.0, we're making changes to the cinterop caching process. It no longer has the `CacheableTask` annotation type. The new recommended approach is to use the `cacheIf` output type to cache the results of the task.

This should resolve issues where `UP-TO-DATE` checks failed to detect changes to header files specified in the definition file, preventing the build system from recompiling the code.

Deprecation of the mimalloc memory allocator

Back in Kotlin 1.9.0, we introduced the new memory allocator, and then we enabled it by default in Kotlin 1.9.20. The new allocator has been designed to make garbage collection more efficient and improve the Kotlin/Native memory manager's runtime performance.

The new memory allocator replaced the previous default allocator, mimalloc. Now, it's time to deprecate mimalloc in the Kotlin/Native compiler.

You can now remove the `-Xallocator=mimalloc` compiler option from your build scripts. If you encounter any issues, please report them to our issue tracker.

For more information on the memory allocator and garbage collection in Kotlin, see Kotlin/Native memory management.

Kotlin/Wasm

Kotlin/Wasm received multiple updates along with support for incremental compilation.

Support for incremental compilation

Previously, when you changed something in your Kotlin code, the Kotlin/Wasm toolchain had to recompile the entire codebase.

Starting from 2.1.0, incremental compilation is supported for Wasm targets. In development tasks, the compiler now recompiles only files relevant to changes from the last compilation, which noticeably reduces the compilation time.

This change currently doubles the compilation speed, and there are plans to improve it further in future releases.

In the current setup, incremental compilation for Wasm targets is disabled by default. To enable incremental compilation, add the following line to your project's `local.properties` or `gradle.properties` file:

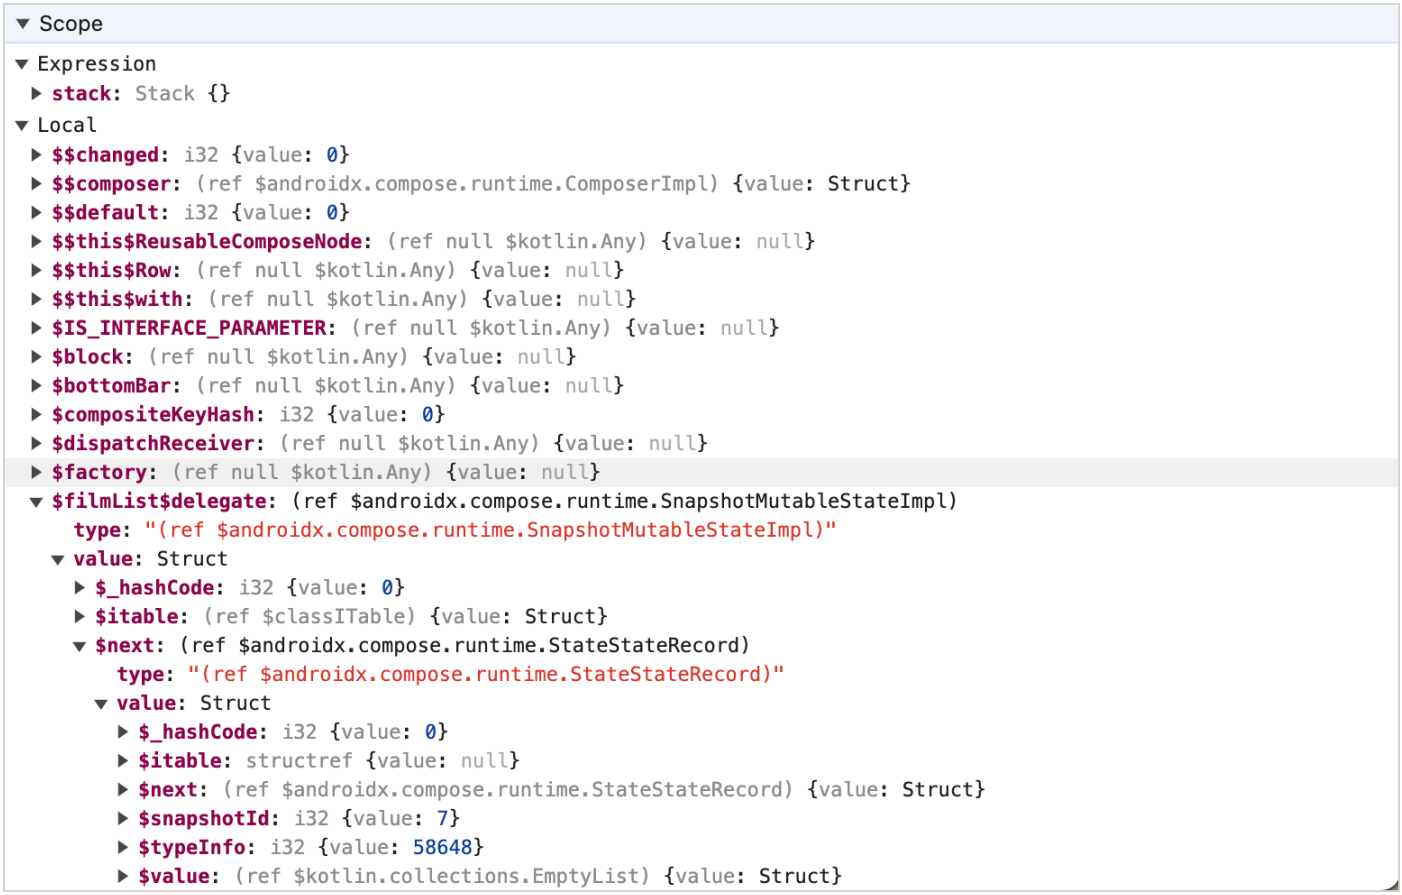
```
# gradle.properties
kotlin.incremental.wasm=true
```

Try out Kotlin/Wasm incremental compilation and share your feedback. Your insights will help make this feature Stable and enabled by default sooner.

Browser APIs moved to the kotlinx-browser stand-alone library

Previously, the declarations for web APIs and related target utilities were part of the Kotlin/Wasm standard library.

In this release, the `org.w3c.*` declarations have been moved from the Kotlin/Wasm standard library to the new kotlinx-browser library. This library also includes other web-related packages, such as `org.khronos.webgl`, `kotlin.dom`, and `kotlinx.browser`.

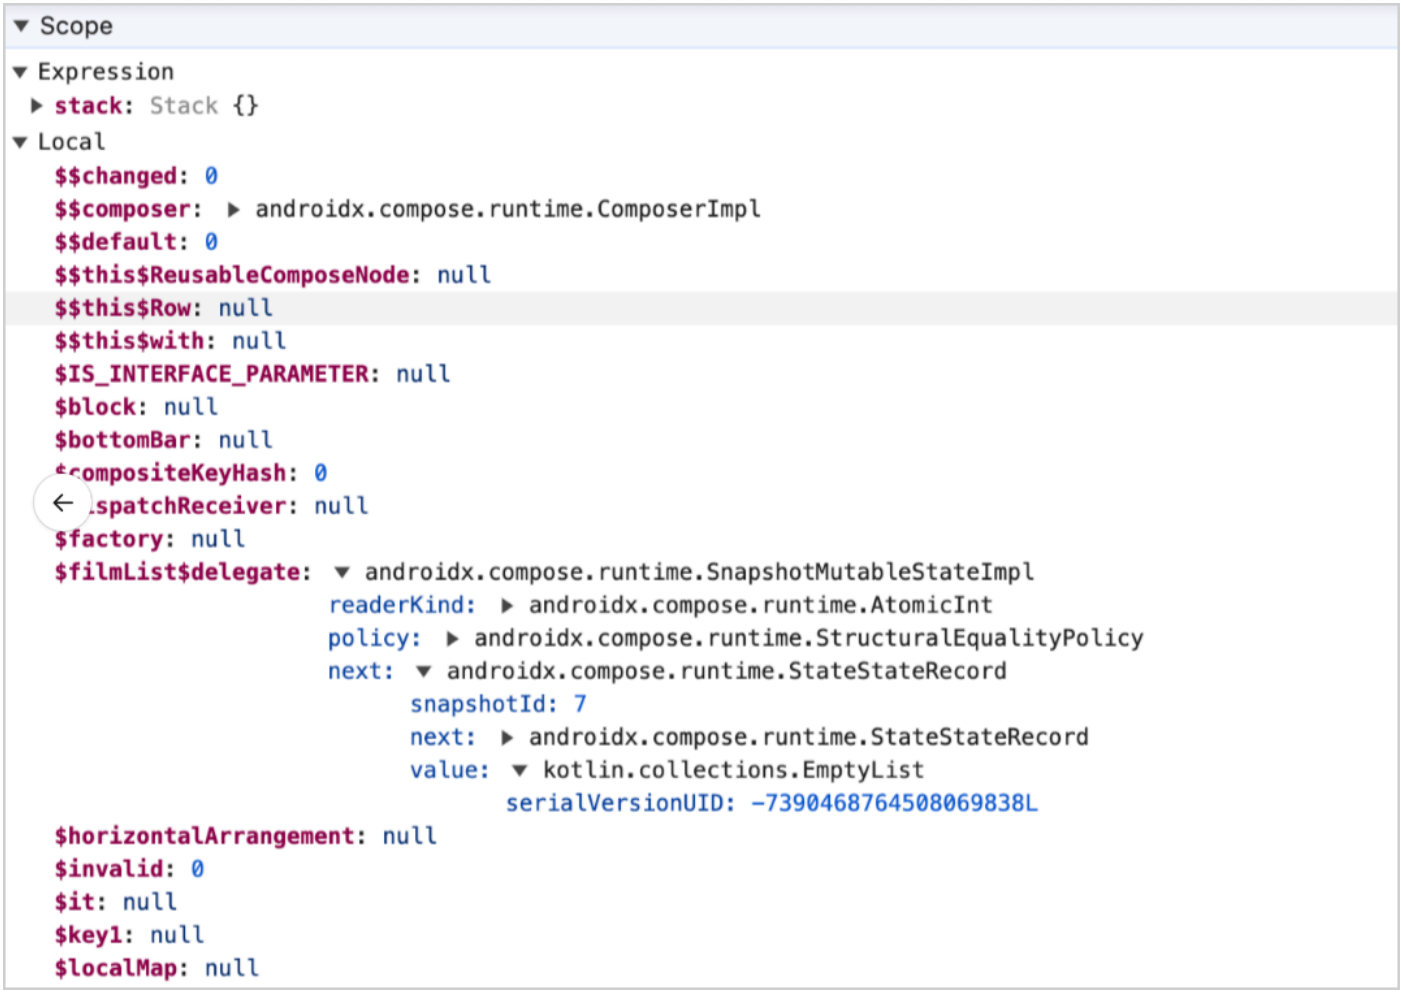


This separation provides modularity, enabling independent updates for web-related APIs outside of Kotlin's release cycle. Additionally, the Kotlin/Wasm standard library now contains only declarations available in any JavaScript environment.

To use the declarations from the moved packages, you need to add the `kotlinx-browser` dependency to your project's build configuration file:

```
// build.gradle.kts
val wasmJsMain by getting {
    dependencies {
        implementation("org.jetbrains.kotlinx:kotlinx-browser:0.3")
    }
}
```

Improved debugging experience for Kotlin/Wasm



Previously, when debugging Kotlin/Wasm code in web browsers, you might have encountered a low-level representation of variable values in the debugging interface. This often made it challenging to track the current state of the application.

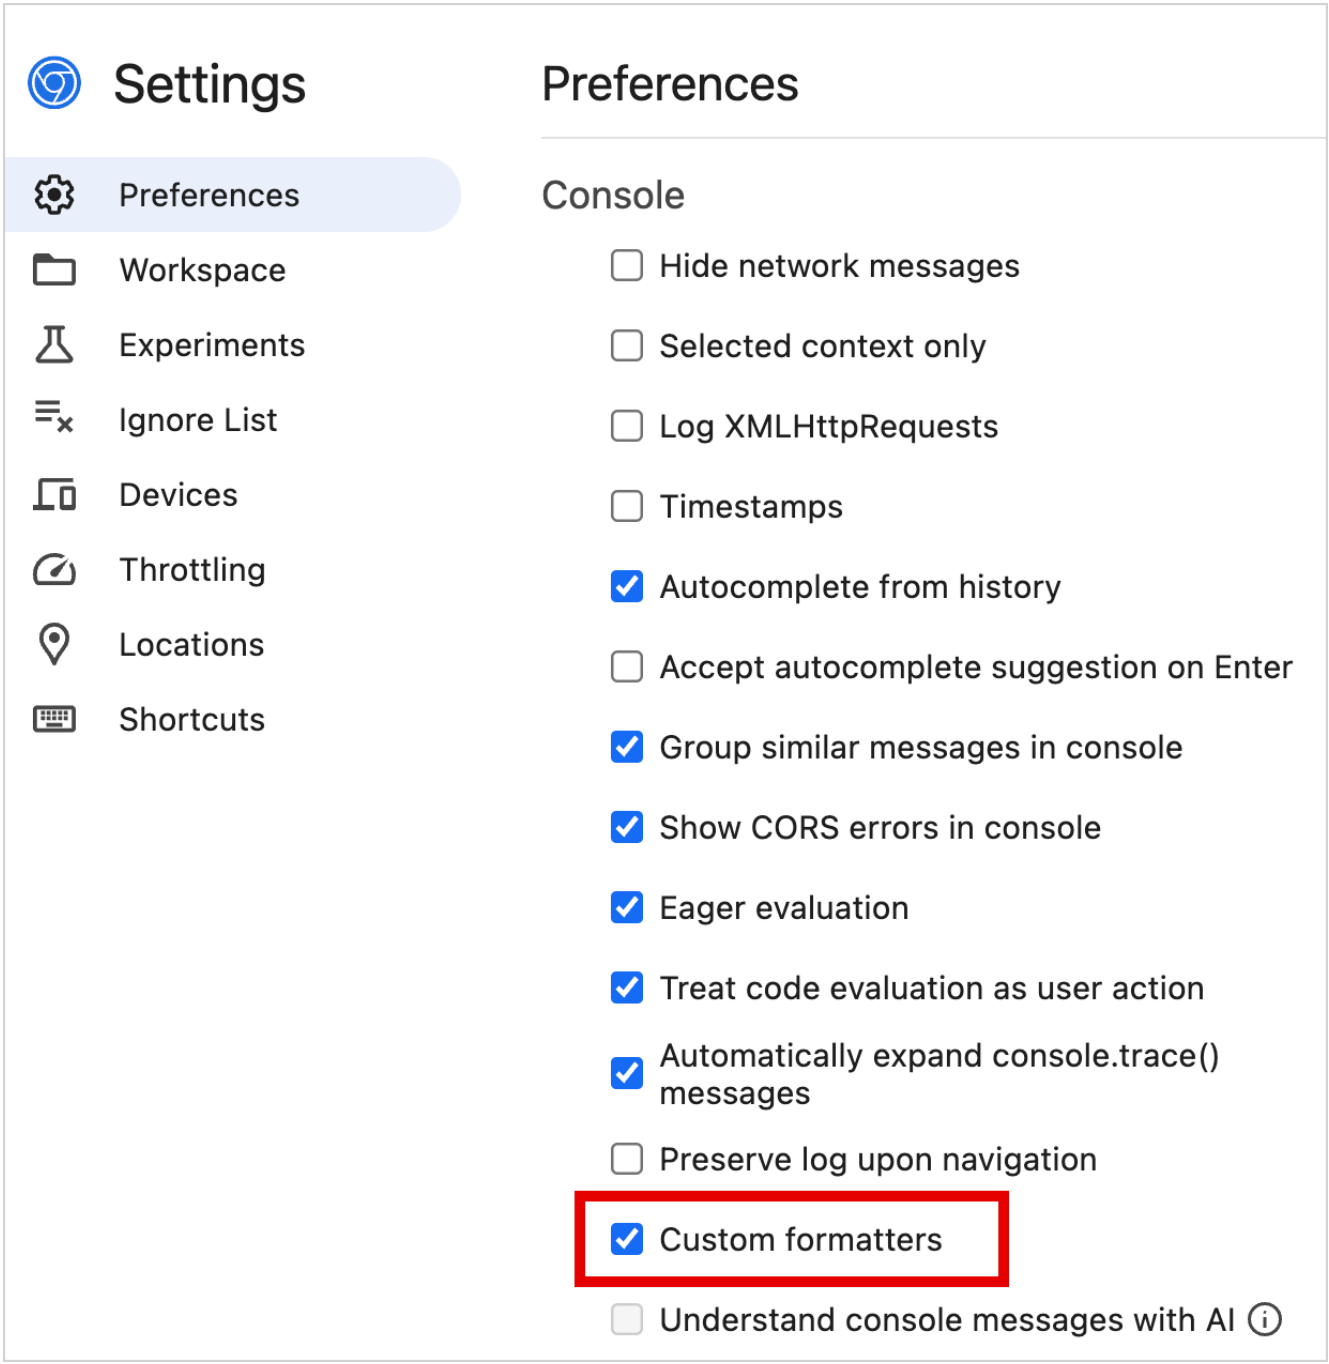
Kotlin/Wasm old debugger

To improve this experience, custom formatters have been added in the variable view. The implementation uses the custom formatters API, which is supported across major browsers like Firefox and Chromium-based ones.

With this change, you can now display and locate variable values in a more user-friendly and comprehensible manner.

Kotlin/Wasm improved debugger

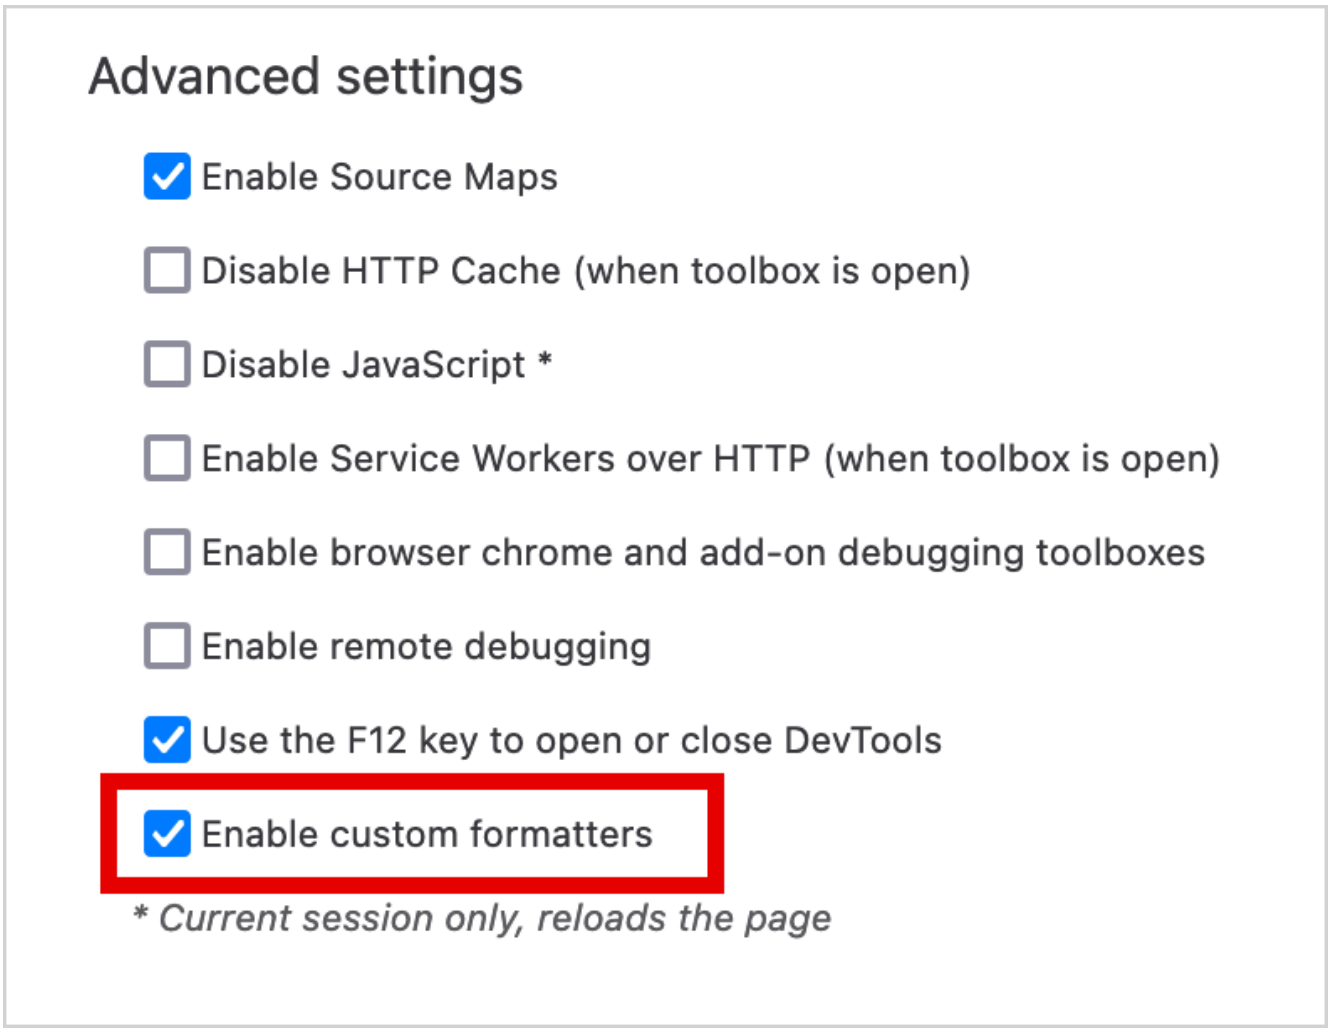
To try the new debugging experience:



1. Add the following compiler option to the `wasmJs {}` compiler options:

```
// build.gradle.kts
kotlin {
    wasmJs {
        // ...

        compilerOptions {
            freeCompilerArgs.add("-Xwasm-debugger-custom-formatters")
        }
    }
}
```



2. Enable custom formatters in your browser:

   - In Chrome DevTools, it's available via **Settings | Preferences | Console**:

Enable custom formatters in Chrome

- In Firefox DevTools, it's available via **Settings | Advanced settings**:

Enable custom formatters in Firefox

Reduced size of Kotlin/Wasm binaries

The size of your Wasm binaries produced by production builds will be reduced by up to 30%, and you may see some performance improvements. This is because the `--closed-world`, `--type-ssa`, and `--type-merging` Binaryen options are now considered safe to use for all Kotlin/Wasm projects and are enabled by default.

Improved JavaScript array interoperability in Kotlin/Wasm

While Kotlin/Wasm's standard library provides the `JsArray<T>` type for JavaScript arrays, there was no direct method to transform `JsArray<T>` into Kotlin's native `Array` or `List` types.

This gap required creating custom functions for array transformations, complicating interoperability between Kotlin and JavaScript code.

This release introduces an adapter function that automatically converts `JsArray<T>` to `Array<T>` and vice versa, simplifying array operations.

Here's an example of conversion between generic types: Kotlin `List<T>` and `Array<T>` to JavaScript `JsArray<T>`.

```
val list: List<JsString> =
    listOf("Kotlin", "Wasm").map { it.toJsString() }

// Uses .toJsArray() to convert List or Array to JsArray
val jsArray: JsArray<JsString> = list.toJsArray()

// Uses .toArray() and .toList() to convert it back to Kotlin types
val kotlinArray: Array<JsString> = jsArray.toArray()
val kotlinList: List<JsString> = jsArray.toList()
```

Similar methods are available for converting typed arrays to their Kotlin equivalents (for example, `IntArray` and `Int32Array`). For detailed information and implementation, see the `kotlinx-browser` repository.

Here's an example of conversion between typed arrays: Kotlin `IntArray` to JavaScript `Int32Array`.

```
import org.khronos.webgl.*

    // ...

    val intArray: IntArray = intArrayOf(1, 2, 3)

    // Uses .toInt32Array() to convert Kotlin IntArray to JavaScript Int32Array
    val jsInt32Array: Int32Array = intArray.toInt32Array()

    // Uses toIntArray() to convert JavaScript Int32Array back to Kotlin IntArray
    val kotlinIntArray: IntArray = jsInt32Array.toIntArray()
```

Support for accessing JavaScript exception details in Kotlin/Wasm

Previously, when a JavaScript exception occurred in Kotlin/Wasm, the `JsException` type provided only a generic message without details from the original JavaScript error.

Starting from Kotlin 2.1.0, you can configure `JsException` to include the original error message and stack trace by enabling a specific compiler option. This provides more context to help diagnose issues originating from JavaScript.

This behavior depends on the `WebAssembly.JSTag` API, which is available only in certain browsers:

- **Chrome**: Supported from version 115
- **Firefox**: Supported from version 129
- **Safari**: Not yet supported

To enable this feature, which is disabled by default, add the following compiler option to your `build.gradle.kts` file:

```
// build.gradle.kts
kotlin {
    wasmJs {
        compilerOptions {
            freeCompilerArgs.add("-Xwasm-attach-js-exception")
        }
    }
}
```

Here's an example demonstrating the new behavior:

```
external object JSON {
    fun <T: JsAny> parse(json: String): T
}

fun main() {
    try {
        JSON.parse("an invalid JSON")
    } catch (e: JsException) {
        println("Thrown value is: ${e.thrownValue}")
        // SyntaxError: Unexpected token 'a', "an invalid JSON" is not valid JSON

        println("Message: ${e.message}")
        // Message: Unexpected token 'a', "an invalid JSON" is not valid JSON

        println("Stacktrace:")
        // Stacktrace:

        // Prints the full JavaScript stack trace
        e.printStackTrace()
    }
}
```

With the `-Xwasm-attach-js-exception` option enabled, `JsException` provides specific details from the JavaScript error. Without the option, `JsException` includes only a generic message stating that an exception was thrown while running JavaScript code.

Deprecation of default exports

As part of the migration to named exports, an error was previously printed to the console when a default import was used for Kotlin/Wasm exports in JavaScript.

In 2.1.0, default imports have been completely removed to fully support named exports.

When coding in JavaScript for the Kotlin/Wasm target, you now need to use the corresponding named imports instead of default imports.

This change marks the last phase of a deprecation cycle to migrate to named exports:

In version 2.0.0: A warning message was printed to the console, explaining that exporting entities via default exports is deprecated.

In version 2.0.20: An error occurred, requesting the use of the corresponding named import.

In version 2.1.0: The use of default imports has been completely removed.

Subproject-specific Node.js settings

You can configure Node.js settings for your project by defining properties of the `NodeJsRootPlugin` class for `rootProject`. In 2.1.0, you can configure these settings for each subproject using a new class, `NodeJsPlugin`. Here's an example demonstrating how to set a specific Node.js version for a subproject:

```
// build.gradle.kts
project.plugins.withType<org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsPlugin> {
    project.the<org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsEnvSpec>().version = "22.0.0"
}
```

To use the new class for the entire project, add the same code in the `allprojects {}` block:

```
// build.gradle.kts
allprojects {
    project.plugins.withType<org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsPlugin> {
        project.the<org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsEnvSpec>().version = "your
Node.js version"
    }
}
```

You can also use Gradle convention plugins to apply the settings to a particular set of subprojects.

Kotlin/JS

Support for non-identifier characters in properties

Kotlin/JS previously did not allow using names for test methods with spaces enclosed in backticks.

Similarly, it was not possible to access JavaScript object properties that contained characters not permitted in Kotlin identifiers, such as hyphens or spaces:

```
external interface Headers {
    var accept: String?

    // Invalid Kotlin identifier due to hyphen
    var `content-length`: String?
}

val headers: Headers = TODO("value provided by a JS library")
val accept = headers.accept
// Causes error due to the hyphen in property name
val length = headers.`content-length`
```

This behavior differed from JavaScript and TypeScript, which allow such properties to be accessed using non-identifier characters.

Starting from Kotlin 2.1.0, this feature is enabled by default. Kotlin/JS now allows you to use the backticks (``) and the `@JsName` annotation to interact with JavaScript properties containing non-identifier characters and to use names for test methods.

Additionally, you can use the `@JsName` and `@JsQualifier` annotations to map Kotlin property names to JavaScript equivalents:

```
object Bar {
    val `property example`: String = "bar"
}

@JsQualifier("fooNamespace")
external object Foo {
    val `property example`: String
}

@JsExport
object Baz {
    val `property example`: String = "bar"
}

fun main() {
    // In JavaScript, this is compiled into Bar.property_example_HASH
    println(Bar.`property example`)
    // In JavaScript, this is compiled into fooNamespace["property example"]
    println(Foo.`property example`)
    // In JavaScript, this is compiled into Baz["property example"]
    println(Baz.`property example`)
}
```

Support for generating ES2015 arrow functions

In Kotlin 2.1.0, Kotlin/JS introduces support for generating ES2015 arrow functions, such as `(a, b) => expression`, instead of anonymous functions.

Using arrow functions can reduce the bundle size of your project, especially when using the experimental `-Xir-generate-inline-anonymous-functions` mode. This also makes the generated code more aligned with modern JS.

This feature is enabled by default when targeting ES2015. Alternatively, you can enable it by using the `-Xes-arrow-functions` command line argument.

Learn more about ES2015 (ECMAScript 2015, ES6) in the official documentation.

Gradle improvements

Kotlin 2.1.0 is fully compatible with Gradle 7.6.3 through 8.6. Gradle versions 8.7 to 8.10 are also supported, with only one exception. If you use the Kotlin Multiplatform Gradle plugin, you may see deprecation warnings in your multiplatform projects calling the `withJava()` function in the JVM target. We plan to fix this issue as soon as possible.

For more information, see the related issue in YouTrack.

You can also use Gradle versions up to the latest Gradle release, but if you do, keep in mind that you might encounter deprecation warnings or some new Gradle features might not work.

Minimum supported AGP version bumped to 7.3.1

Starting with Kotlin 2.1.0, the minimum supported Android Gradle plugin version is 7.3.1.

Minimum supported Gradle version bumped to 7.6.3

Starting with Kotlin 2.1.0, the minimum supported Gradle version is 7.6.3.

New API for Kotlin Gradle plugin extensions

Kotlin 2.1.0 introduces a new API to make it easier to create your own plugins for configuring the Kotlin Gradle plugin. This change deprecates the `KotlinTopLevelExtension` and `KotlinTopLevelExtensionConfig` interfaces and introduces the following interfaces for plugin authors:

Name	Description
`KotlinBaseExtension`	A plugin DSL extension type for configuring common Kotlin JVM, Android, and Multiplatform plugin options for the entire project: • `org.jetbrains.kotlin.jvm` • `org.jetbrains.kotlin.android` • `org.jetbrains.kotlin.multiplatform`
`KotlinJvmExtension`	A plugin DSL extension type for configuring Kotlin **JVM** plugin options for the entire project.
`KotlinAndroidExtension`	A plugin DSL extension type for configuring Kotlin **Android** plugin options for the entire project.

For example, if you want to configure compiler options for both JVM and Android projects, use `KotlinBaseExtension`:

```
configure<KotlinBaseExtension> {
    if (this is HasConfigurableKotlinCompilerOptions<*>) {
        with(compilerOptions) {
            if (this is KotlinJvmCompilerOptions) {
                jvmTarget.set(JvmTarget.JVM_17)
            }
        }
    }
}
```

This configures the JVM target to 17 for both JVM and Android projects.

To configure compiler options specifically for JVM projects, use `KotlinJvmExtension`:

```
configure<KotlinJvmExtension> {
    compilerOptions {
        jvmTarget.set(JvmTarget.JVM_17)
    }

    target.mavenPublication {
        groupId = "com.example"
        artifactId = "example-project"
        version = "1.0-SNAPSHOT"
    }
}
```

This example similarly configures the JVM target to 17 for JVM projects. It also configures a Maven publication for the project so that its output is published to a Maven repository.

You can use the `KotlinAndroidExtension` in exactly the same way.

Compiler symbols hidden from the Kotlin Gradle plugin API

Previously, KGP included `org.jetbrains.kotlin:kotlin-compiler-embeddable` in its runtime dependencies, making internal compiler symbols available in the build script classpath. These symbols were intended for internal use only.

Starting with Kotlin 2.1.0, KGP bundles a subset of `org.jetbrains.kotlin:kotlin-compiler-embeddable` class files in its JAR file and progressively removes them. This change aims to prevent compatibility issues and simplify KGP maintenance.

If other parts of your build logic, such as plugins like `kotlinter`, depend on a different version of `org.jetbrains.kotlin:kotlin-compiler-embeddable` than the one bundled with KGP, it can lead to conflicts and runtime exceptions.

To prevent such issues, KGP now shows a warning if `org.jetbrains.kotlin:kotlin-compiler-embeddable` is present in the build classpath alongside KGP.

As a long-term solution, if you're a plugin author using `org.jetbrains.kotlin:kotlin-compiler-embeddable` classes, we recommend running them in an isolated classloader. For example, you can achieve it using the Gradle Workers API with classloader or process isolation.

Using the Gradle Workers API

This example demonstrates how to safely use the Kotlin compiler in a project producing a Gradle plugin. First, add a compile-only dependency in your build script. This makes the symbol available at compile time only:

```
// build.gradle.kts
dependencies {
    compileOnly("org.jetbrains.kotlin:kotlin-compiler-embeddable:2.4.20")
}
```

Next, define a Gradle work action to print the Kotlin compiler version:

```
import org.gradle.workers.WorkAction
import org.gradle.workers.WorkParameters
import org.jetbrains.kotlin.config.KotlinCompilerVersion
abstract class ActionUsingKotlinCompiler : WorkAction<WorkParameters.None> {
    override fun execute() {
        println("Kotlin compiler version: ${KotlinCompilerVersion.getVersion()}")
    }
}
```

Now create a task that submits this action to the worker executor using classloader isolation:

```
import org.gradle.api.DefaultTask
import org.gradle.api.file.ConfigurableFileCollection
import org.gradle.api.tasks.Classpath
import org.gradle.api.tasks.TaskAction
import org.gradle.workers.WorkerExecutor
import javax.inject.Inject
abstract class TaskUsingKotlinCompiler: DefaultTask() {
    @get:Inject
    abstract val executor: WorkerExecutor

    @get:Classpath
    abstract val kotlinCompiler: ConfigurableFileCollection

    @TaskAction
    fun compile() {
        val workQueue = executor.classLoaderIsolation {
            classpath.from(kotlinCompiler)
        }
        workQueue.submit(ActionUsingKotlinCompiler::class.java) {}
    }
}
```

Finally, configure the Kotlin compiler classpath in your Gradle plugin:

```
import org.gradle.api.Plugin
import org.gradle.api.Project
abstract class MyPlugin: Plugin<Project> {
    override fun apply(target: Project) {
        val myDependencyScope = target.configurations.create("myDependencyScope")
        target.dependencies.add(myDependencyScope.name,
"$KOTLIN_COMPILER_EMBEDDABLE:$KOTLIN_COMPILER_VERSION")
        val myResolvableConfiguration = target.configurations.create("myResolvable") {
            extendsFrom(myDependencyScope)
        }
        target.tasks.register("myTask", TaskUsingKotlinCompiler::class.java) {
            kotlinCompiler.from(myResolvableConfiguration)
        }
    }

    companion object {
        const val KOTLIN_COMPILER_EMBEDDABLE = "org.jetbrains.kotlin:kotlin-compiler-embeddable"
        const val KOTLIN_COMPILER_VERSION = "2.4.20"
    }
}
```

Compose compiler updates

Support for multiple stability configuration files

The Compose compiler can interpret multiple stability configuration files, but the `stabilityConfigurationFile` option of the Compose Compiler Gradle plugin previously allowed for only a single file to be specified. In Kotlin 2.1.0, this functionality was reworked to allow you to use several stability configuration files for a single module:

- The `stabilityConfigurationFile` option is deprecated.
- There is a new option, `stabilityConfigurationFiles`, with the type `ListProperty<RegularFile>`.

Here's how to pass several files to the Compose compiler using the new option:

```
// build.gradle.kt
composeCompiler {
    stabilityConfigurationFiles.addAll(
        project.layout.projectDirectory.file("configuration-file1.conf"),
        project.layout.projectDirectory.file("configuration-file2.conf"),
    )
}
```

Pausable composition

Pausable composition is a new Experimental feature that changes how the compiler generates skippable functions. With this feature enabled, composition can be suspended on skipping points during runtime, allowing long-running composition processes to be split across multiple frames. Pausable composition is used in lazy lists and other performance-intensive components for prefetching content that might cause frames to drop when executed in a blocking manner.

To try out pausable composition, add the following feature flag in the Gradle configuration for the Compose compiler:

```
// build.gradle.kts
composeCompiler {
    featureFlags = setOf(
        ComposeFeatureFlag.PausableComposition
    )
}
```

Runtime support for this feature was added in the 1.8.0-alpha02 version of `androidx.compose.runtime`. The feature flag has no effect when used with older runtime versions.

Changes to open and overridden @Composable functions

Virtual (open, abstract, and overridden) `@Composable` functions can no longer be restartable. The codegen for restartable groups was generating calls that did not work correctly with inheritance, resulting in runtime crashes.

This means that virtual functions won't be restarted or skipped: whenever their state is invalidated, runtime will recompose their parent composable instead. If your code is sensitive to recompositions, you may notice changes in runtime behavior.

Performance improvements

The Compose compiler used to create a full copy of module's IR to transform `@Composable` types. Apart from increased memory consumption when copying elements that were not related to Compose, this behavior was also breaking downstream compiler plugins in certain edge cases.

This copy operation was removed, resulting in potentially faster compilation times.

Standard library

Changes to the deprecation severity of standard library APIs

In Kotlin 2.1.0, we are raising the deprecation severity level of several standard library APIs from warning to error. If your code relies on these APIs, you need to update it to ensure compatibility. The most notable changes include:

- **Locale-sensitive case conversion functions for `Char` and `String` are deprecated:** Functions like `Char.toLowerCase()`, `Char.toUpperCase()`, `String.toUpperCase()`, and `String.toLowerCase()` are now deprecated, and using them results in an error. Replace them with locale-agnostic function alternatives or other case conversion mechanisms. If you want to continue using the default locale, replace calls like `String.toLowerCase()` with `String.lowercase(Locale.getDefault())`, explicitly specifying the locale. For a locale-agnostic conversion, replace them with `String.lowercase()`, which uses the invariant locale by default.
- **Kotlin/Native freezing API is deprecated:** Using the freezing-related declarations previously marked with the `@FreezingIsDeprecated` annotation now results in an error. This change reflects the transition from the legacy memory manager in Kotlin/Native, which required freezing objects to share them between threads. To learn how to migrate from freezing-related APIs in the new memory model, see the Kotlin/Native migration guide. For more information, see the announcement about the deprecation of freezing.
- **`appendln()` is deprecated in favor of `appendLine()`:** The `StringBuilder.appendln()` and `Appendable.appendln()` functions are now deprecated, and using them results in an error. To replace them, use the `StringBuilder.appendLine()` or `Appendable.appendLine()` functions instead. The `appendln()` function is deprecated because, on Kotlin/JVM, it uses the `line.separator` system property, which has a different default value on each OS. On Kotlin/JVM, this property defaults to `\r\n` (CR LF) on Windows and `\n` (LF) on other systems. On the other hand, the `appendLine()` function consistently uses `\n` (LF) as the line separator, ensuring consistent behavior across platforms.

For a complete list of affected APIs in this release, see the KT-71628 YouTrack issue.

Stable file tree traversal extensions for java.nio.file.Path

Kotlin 1.7.20 introduced Experimental extension functions for the `java.nio.file.Path` class, which allows you to walk through a file tree. In Kotlin 2.1.0, the following file tree traversal extensions are now Stable:

- `walk()` lazily traverses the file tree rooted at the specified path.
- `fileVisitor()` makes it possible to create a `FileVisitor` separately. `FileVisitor` specifies the actions to be performed on directories and files during traversal.
- `visitFileTree(fileVisitor: FileVisitor, ...)` traverses through a file tree, invoking the specified `FileVisitor` on each encountered entry, and it uses the `java.nio.file.Files.walkFileTree()` function under the hood.
- `visitFileTree(..., builderAction: FileVisitorBuilder.() -> Unit)` creates a `FileVisitor` with the provided `builderAction` and calls the `visitFileTree(fileVisitor, ...)` function.
- `sealed interface FileVisitorBuilder` allows you to define a custom `FileVisitor` implementation.
- `enum class PathWalkOption` provides traversal options for the `Path.walk()` function.

The examples below demonstrate how to use these file traversal APIs to create custom `FileVisitor` behaviors, which allows you to define specific actions for visiting files and directories.

For instance, you can explicitly create a `FileVisitor` and use it later:

```
val cleanVisitor = fileVisitor {
    onPreVisitDirectory { directory, attributes ->
        // Placeholder: Add logic on visiting directories
        FileVisitResult.CONTINUE
    }

    onVisitFile { file, attributes ->
        // Placeholder: Add logic on visiting files
        FileVisitResult.CONTINUE
    }
}

// Placeholder: Add logic here for general setup before traversal
projectDirectory.visitFileTree(cleanVisitor)
```

You can also create a `FileVisitor` with the `builderAction` and use it immediately for the traversal:

```
projectDirectory.visitFileTree {
    // Defines the builderAction:
    onPreVisitDirectory { directory, attributes ->
        // Some logic on visiting directories
        FileVisitResult.CONTINUE
    }

    onVisitFile { file, attributes ->
        // Some logic on visiting files
        FileVisitResult.CONTINUE
    }
}
```

Additionally, you can traverse a file tree rooted at the specified path with the `walk()` function:

```
fun traverseFileTree() {
    val cleanVisitor = fileVisitor {
        onPreVisitDirectory { directory, _ ->
            if (directory.name == "build") {
                directory.toFile().deleteRecursively()
                FileVisitResult.SKIP_SUBTREE
            } else {
                FileVisitResult.CONTINUE
            }
        }

        // Deletes files with the .class extension
        onVisitFile { file, _ ->
            if (file.extension == "class") {
                file.deleteExisting()
            }
            FileVisitResult.CONTINUE
        }
    }

    // Sets up the root directory and files
    val rootDirectory = createTempDirectory("Project")

    // Creates the src directory with A.kt and A.class files
    rootDirectory.resolve("src").let { srcDirectory ->
        srcDirectory.createDirectory()
        srcDirectory.resolve("A.kt").createFile()
        srcDirectory.resolve("A.class").createFile()
    }

    // Creates the build directory with a Project.jar file
    rootDirectory.resolve("build").let { buildDirectory ->
        buildDirectory.createDirectory()
        buildDirectory.resolve("Project.jar").createFile()
    }

    // Uses the walk() function:
    val directoryStructure = rootDirectory.walk(PathWalkOption.INCLUDE_DIRECTORIES)
        .map { it.relativeTo(rootDirectory).toString() }
        .toList().sorted()
    println(directoryStructure)
    // "[, build, build/Project.jar, src, src/A.class, src/A.kt]"

    // Traverses the file tree with cleanVisitor, applying the
rootDirectory.visitFileTree(cleanVisitor) cleanup rules
    val directoryStructureAfterClean = rootDirectory.walk(PathWalkOption.INCLUDE_DIRECTORIES)
        .map { it.relativeTo(rootDirectory).toString() }
        .toList().sorted()
    println(directoryStructureAfterClean)
    // "[, src, src/A.kt]"
}
```

Documentation updates

The Kotlin documentation has received some notable changes:

Language concepts

- Improved Null safety page – Learn how to handle `null` values safely in your code.

- Improved Objects declarations and expressions page – Learn how to define a class and create an instance in a single step.
- Improved When expressions and statements section – Learn about the `when` conditional and how you can use it.
- Updated Kotlin roadmap, Kotlin evolution principles, and Kotlin language features and proposals pages – Learn about Kotlin's plans, ongoing developments, and guiding principles.

Compose compiler

- Compose compiler documentation now located in the Compiler and plugins section – Learn about the Compose compiler, the compiler options, and the steps to migrate.

API references

- New Kotlin Gradle plugins API reference – Explore the API references for the Kotlin Gradle plugin and the Compose compiler Gradle plugin.

Multiplatform development

- New Building a Kotlin library for multiplatform page – Learn how to design your Kotlin libraries for Kotlin Multiplatform.
- New Introduction to Kotlin Multiplatform page – Learn about Kotlin Multiplatform's key concepts, dependencies, libraries, and more.
- New iOS integration section – Learn how to integrate a Kotlin Multiplatform shared module into your iOS app.
- New Kotlin/Native's definition file page – Learn how to create a definition file to consume C and Objective-C libraries.
- Get started with WASI – Learn how to run a simple Kotlin/Wasm application using WASI in various WebAssembly virtual machines.

Tooling

- New Dokka migration guide – Learn how to migrate to Dokka Gradle plugin v2.

Compatibility guide for Kotlin 2.1.0

Kotlin 2.1.0 is a feature release and can, therefore, bring changes that are incompatible with your code written for earlier versions of the language. Find the detailed list of these changes in the Compatibility guide for Kotlin 2.1.0.

Install Kotlin 2.1.0

Starting from IntelliJ IDEA 2023.3 and Android Studio Iguana (2023.2.1) Canary 15, the Kotlin plugin is distributed as a bundled plugin included in your IDE. This means that you can't install the plugin from JetBrains Marketplace anymore.

To update to the new Kotlin version, change the Kotlin version to 2.1.0 in your build scripts.

Compatibility guide for Kotlin 2.1.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 2.0 to Kotlin 2.1.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Remove language versions 1.4 and 1.5

Issue: KT-60521

Component: Core language

Incompatible change type: source

Short summary: Kotlin 2.1 introduces language version 2.1 and removes support for language versions 1.4 and 1.5. Language versions 1.6 and 1.7 are deprecated.

Deprecation cycle:

- 1.6.0: report a warning for language version 1.4
- 1.9.0: report a warning for language version 1.5
- 2.1.0: report a warning for language versions 1.6 and 1.7; raise the warning to an error for language versions 1.4 and 1.5

Change the typeOf() function behavior on Kotlin/Native

Issue: KT-70754

Component: Core language

Incompatible change type: behavioral

Short summary: The behavior of the `typeOf()` function on Kotlin/Native is aligned with Kotlin/JVM to ensure consistency across platforms.

Deprecation cycle:

- 2.1.0: align the `typeOf()` function behavior on Kotlin/Native

Prohibit exposing types through type parameters' bounds

Issue: KT-69653

Component: Core language

Incompatible change type: source

Short summary: Exposing types with lower visibility through type parameter bounds is now prohibited, addressing inconsistencies in type visibility rules. This change ensures that bounds on type parameters follow the same visibility rules as classes, preventing issues like IR validation errors in the JVM.

Deprecation cycle:

- 2.1.0: report a warning for exposing types via type parameter bounds with lower visibility
- 2.2.0: raise the warning to an error

Prohibit inheriting an abstract var property and a val property with the same name

Issue: KT-58659

Component: Core language

Incompatible change type: source

Short summary: If a class inherits an abstract `var` property from an interface and a `val` property with the same name from a superclass, it now triggers a compilation error. This resolves runtime crashes caused by missing setters in such cases.

Deprecation cycle:

- 2.1.0: report a warning (or an error in progressive mode) when a class inherits an abstract `var` property from an interface and a `val` property with the same name from a superclass
- 2.2.0: raise the warning to an error

Report error when accessing uninitialized enum entries

Issue: KT-68451

Component: Core language

Incompatible change type: source

Short summary: The compiler now reports an error when uninitialized enum entries are accessed during enum class or entry initialization. This aligns the behavior with member property initialization rules, preventing runtime exceptions and ensuring consistent logic.

Deprecation cycle:

- 2.1.0: report an error when accessing uninitialized enum entries

Changes in K2 smart cast propagation

Issue: KTLC-34

Component: Core language

Incompatible change type: behavioral

Short summary: The K2 compiler changes its behavior for smart cast propagation by introducing bidirectional propagation of type information for inferred variables, like `val x = y`. Explicitly typed variables, such as `val x: T = y`, no longer propagate type information, ensuring stricter adherence to declared types.

Deprecation cycle:

- 2.1.0: enable the new behavior

Correct the handling of member-extension property overrides in Java subclasses

Issue: KTLC-35

Component: Core language

Incompatible change type: behavioral

Short summary: The getter for member-extension properties overridden by Java subclasses is now hidden in the subclass's scope, aligning its behavior with that of regular Kotlin properties.

Deprecation cycle:

- 2.1.0: enable the new behavior

Correct visibility alignment for getters and setters of var properties overriding a protected val

Issue: KTLC-36

Component: Core language

Incompatible change type: binary

Short summary: The visibility of getters and setters for `var` properties overriding a `protected val` property is now consistent, with both inheriting the visibility of the overridden `val` property.

Deprecation cycle:

- 2.1.0: enforce consistent visibility for both getters and setters in K2; K1 remains unaffected

Raise severity of JSpecify nullability mismatch diagnostics to errors

Issue: KTLC-11

Component: Core language

Incompatible change type: source

Short summary: Nullability mismatches from `org.jspecify.annotations`, such as `@NonNull`, `@Nullable`, and `@NullMarked` are now treated as errors instead of warnings, enforcing stricter type safety for Java interoperability. To adjust the severity of these diagnostics, use the `-Xnullability-annotations` compiler option.

Deprecation cycle:

- 1.6.0: report warnings for potential nullability mismatches
- 1.8.20: expand warnings to specific JSpecify annotations, including: `@Nullable`, `@NullnessUnspecified`, `@NullMarked`, and legacy annotations in `org.jspecify.nullness` (JSpecify 0.2 and earlier)
- 2.0.0: add support for the `@NonNull` annotation
- 2.1.0: change default mode to `strict` for JSpecify annotations, converting warnings into errors; use `-Xnullability-annotations=@org.jspecify.annotations:warning` or `-Xnullability-annotations=@org.jspecify.annotations:ignore` to override the default behavior

Change overload resolution to prioritize extension functions over invoke calls in ambiguous cases

Issue: KTLC-37

Component: Core language

Incompatible change type: behavioral

Short summary: Overload resolution now consistently prioritizes extension functions over invoke calls in ambiguous cases. This resolves inconsistencies in the resolution logic for local functions and properties. The change applies only after recompilation, without affecting precompiled binaries.

Deprecation cycle:

- 2.1.0: change overload resolution to consistently prioritize extension functions over `invoke` calls for extension functions with matching signatures; this change applies only after recompilation and does not affect precompiled binaries

Prohibit returning nullable values from lambdas in SAM constructors of JDK function interfaces

Issue: KTLC-42

Component: Core language

Incompatible change type: source

Short summary: Returning nullable values from lambdas in SAM constructors of JDK function interfaces now triggers a compilation error if the specified type argument is non-nullable. This resolves issues where nullability mismatches could lead to runtime exceptions, ensuring stricter type safety.

Deprecation cycle:

- 2.0.0: report a deprecation warning for nullable return values in SAM constructors of JDK function interfaces
- 2.1.0: enable the new behavior by default

Correct handling of private members conflicting with public members in Kotlin/Native

Issue: KTLC-43

Component: Core language

Incompatible change type: behavioral

Short summary: In Kotlin/Native, private members no longer override or conflict with public members in a superclass, aligning behavior with Kotlin/JVM. This resolves inconsistencies in override resolution and eliminates unexpected behavior caused by separate compilation.

Deprecation cycle:

- 2.1.0: private functions and properties in Kotlin/Native no longer override or affect public members in a superclass, aligning with JVM behavior

Forbid access to private operator functions in public inline functions

Issue: KTLC-71

Component: Core language

Incompatible change type: source

Short summary: Private operator functions such as `getValue()`, `setValue()`, `provideDelegate()`, `hasNext()`, and `next()` can no longer be accessed in public inline functions.

Deprecation cycle:

- 2.0.0: report a deprecation warning for accessing private operator functions in public inline functions
- 2.1.0: raise the warning to an error

Prohibit passing invalid arguments to invariant parameters annotated with @UnsafeVariance

Issue: KTLC-72

Component: Core language

Incompatible change type: source

Short summary: The compiler now ignores `@UnsafeVariance` annotations during type checks, enforcing stricter type safety for invariant type parameters. This prevents invalid calls that rely on `@UnsafeVariance` to bypass expected type checks.

Deprecation cycle:

- 2.1.0: activate the new behavior

Report nullability errors for error-level nullable arguments of warning-level Java types

Issue: KTLC-100

Component: Core language

Incompatible change type: source

Short summary: The compiler now detects nullability mismatches in Java methods where a warning-level nullable type contains type arguments with stricter, error-level nullability. This ensures that previously ignored errors in type arguments are reported correctly.

Deprecation cycle:

- 2.0.0: report a deprecation warning for nullability mismatches in Java methods with stricter type arguments
- 2.1.0: raise the warning to an error

Report implicit usages of inaccessible types

Issue: KTLC-3

Component: Core language

Incompatible change type: source

Short summary: The compiler now reports usages of inaccessible types in function literals and type arguments, preventing compilation and runtime failures caused by incomplete type information.

Deprecation cycle:

- 2.0.0: report warnings for function literals with parameters or receivers of inaccessible non-generic types and for types with inaccessible type argument; report errors for function literals with parameters or receivers of inaccessible generic types and for types with inaccessible generic type arguments in specific scenarios
- 2.1.0: raise warnings to errors for function literals with parameters and receivers of inaccessible non-generic types
- 2.2.0: raise warnings to errors for types with inaccessible type arguments

Standard library

Deprecate locale-sensitive case conversion functions for Char and String

Issue: KT-43023

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Among other Kotlin standard library APIs, locale-sensitive case conversion functions for `Char` and `String`, such as `Char.toUpperCase()` and `String.toLowerCase()`, are deprecated. Replace them with locale-agnostic alternatives like `String.lowercase()` or explicitly specify the locale for locale-sensitive behavior, such as `String.lowercase(Locale.getDefault())`.

For a comprehensive list of deprecated Kotlin standard library APIs in Kotlin 2.1.0, see KT-71628.

Deprecation cycle:

- 1.4.30: introduce locale-agnostic alternatives as experimental API
- 1.5.0: deprecate locale-sensitive case conversion functions with a warning
- 2.1.0: raise the warning to an error

Remove kotlin-stdlib-common JAR artifact

Issue: KT-62159

Component: kotlin-stdlib

Incompatible change type: binary

Short summary: The `kotlin-stdlib-common.jar` artifact, previously used for legacy multiplatform declarations metadata, is deprecated and replaced by `.klib` files as the standard format for common multiplatform declarations metadata. This change does not affect the main `kotlin-stdlib.jar` or `kotlin-stdlib-all.jar` artifacts.

Deprecation cycle:

- 2.1.0: deprecate and remove `kotlin-stdlib-common.jar` artifact

Deprecate appendln() in favor of appendLine()

Issue: KTLC-27

Component: kotlin-stdlib

Incompatible change type: source

Short summary: `StringBuilder.appendln()` is deprecated in favor of `StringBuilder.appendLine()`.

Deprecation cycle:

- 1.4.0: the `appendln()` function is deprecated; report a warning on use
- 2.1.0: raise the warning to an error

Deprecate freezing-related APIs in Kotlin/Native

Issue: KT-69545

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Freezing-related APIs in Kotlin/Native, previously marked with the `@FreezingIsDeprecated` annotation, are now deprecated. This aligns with the introduction of the new memory manager that removes the need for freezing objects for thread sharing. For migration details, see the Kotlin/Native migration guide.

Deprecation cycle:

- 1.7.20: deprecate freezing-related APIs with a warning
- 2.1.0: raise the warning to an error

Change Map.Entry behavior to fail-fast on structural modification

Issue: KTLC-23

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: Accessing a `Map.Entry` key-value pair after its associated map has been structurally modified now throws a `ConcurrentModificationException`.

Deprecation cycle:

- 2.1.0: throw an exception when a map structural modification is detected

Tools

Deprecate KotlinCompilationOutput#resourcesDirProvider

Issue: KT-69255

Component: Gradle

Incompatible change type: source

Short summary: The `KotlinCompilationOutput#resourcesDirProvider` field is deprecated. Use `KotlinSourceSet.resources` in your Gradle build script instead to add additional resource directories.

Deprecation cycle:

- 2.1.0: `KotlinCompilationOutput#resourcesDirProvider` is deprecated

Deprecate registerKotlinJvmCompileTask(taskName, moduleName) function

Issue: KT-69927

Component: Gradle

Incompatible change type: source

Short summary: The `registerKotlinJvmCompileTask(taskName, moduleName)` function is deprecated in favor of the new `registerKotlinJvmCompileTask(taskName, compilerOptions, explicitApiMode)` function, which now accepts `KotlinJvmCompilerOptions`. This allows you to pass a `compilerOptions` instance, typically from an extension or target, with values used as conventions for the task's options.

Deprecation cycle:

- 2.1.0: the `registerKotlinJvmCompileTask(taskName, moduleName)` function is deprecated

Deprecate registerKaptGenerateStubsTask(taskName) function

Issue: KT-70383

Component: Gradle

Incompatible change type: source

Short summary: The `registerKaptGenerateStubsTask(taskName)` function is deprecated. Use the new `registerKaptGenerateStubsTask(compileTask, kaptExtension, explicitApiMode)` function instead. This new version allows you to link values as conventions from the relevant `KotlinJvmCompile` task, ensuring both tasks are using the same set of options.

Deprecation cycle:

- 2.1.0: the `registerKaptGenerateStubsTask(taskName)` function is deprecated

Deprecate KotlinTopLevelExtension and KotlinTopLevelExtensionConfig interfaces

Issue: KT-71602

Component: Gradle

Incompatible change type: behavioral

Short summary: `KotlinTopLevelExtension` and `KotlinTopLevelExtensionConfig` interfaces are deprecated in favor of a new `KotlinTopLevelExtension` interface. This interface merges `KotlinTopLevelExtensionConfig`, `KotlinTopLevelExtension`, and `KotlinProjectExtension` to streamline API hierarchy, and provide official access to the JVM toolchain and compiler properties.

Deprecation cycle:

- 2.1.0: the `KotlinTopLevelExtension` and `KotlinTopLevelExtensionConfig` interfaces are deprecated

Remove kotlin-compiler-embeddable from build runtime dependencies

Issue: KT-61706

Component: Gradle

Incompatible change type: source

Short summary: The `kotlin-compiler-embeddable` dependency is removed from the runtime in Kotlin Gradle Plugin (KGP). Required modules are now included directly in KGP artifacts, with the Kotlin language version limited to 2.0 to support compatibility with Gradle Kotlin runtime in versions below 8.2.

Deprecation cycle:

- 2.1.0: report a warning on using `kotlin-compiler-embeddable`
- 2.2.0: raise the warning to an error

Hide compiler symbols from the Kotlin Gradle Plugin API

Issue: KT-70251

Component: Gradle

Incompatible change type: source

Short summary: Compiler module symbols bundled within the Kotlin Gradle Plugin (KGP), such as `KotlinCompilerVersion`, are hidden from the public API to prevent unintended access in build scripts.

Deprecation cycle:

- 2.1.0: report a warning on accessing these symbols
- 2.2.0: raise the warning to an error

Add support for multiple stability configuration files

Issue: KT-68345

Component: Gradle

Incompatible change type: source

Short summary: The `stabilityConfigurationFile` property in the Compose extension is deprecated in favor of a new `stabilityConfigurationFiles` property, which allows specifying multiple configuration files.

Deprecation cycle:

- 2.1.0: `stabilityConfigurationFile` property is deprecated

Remove deprecated platform plugin IDs

Issue: KT-65565

Component: Gradle

Incompatible change type: source

Short summary: Support for these platform plugin IDs have been removed:

- `kotlin-platform-common`
- `org.jetbrains.kotlin.platform.common`

Deprecation cycle:

- 1.3: the platform plugin IDs are deprecated
- 2.1.0: the platform plugin IDs are no longer supported

What's new in Kotlin 2.0.20

Released: August 22, 2024

The Kotlin 2.0.20 release is out! This version includes performance improvements and bug fixes for Kotlin 2.0.0, where we announced the Kotlin K2 compiler as Stable. Here are some additional highlights from this release:

- The data class copy function to have the same visibility as the constructor
- Static accessors for source sets from the default target hierarchy are now available in multiplatform projects
- Concurrent marking for Kotlin/Native has been made possible in the garbage collector
- The `@ExperimentalWasmDsl` annotation in Kotlin/Wasm has a new location
- Support has been added for Gradle versions 8.6–8.8
- A new option allows sharing JVM artifacts between Gradle projects as class files
- The Compose compiler has been updated
- Support for UUIDs has been added to the common Kotlin standard library

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 2.0.20 are bundled in the latest IntelliJ IDEA and Android Studio. You don't need to update the Kotlin plugin in your IDE. All you need to do is to change the Kotlin version to 2.0.20 in your build scripts.

See Update to a new release for details.

Language

Kotlin 2.0.20 begins to introduce changes to improve consistency in data classes and replace the Experimental context receivers feature.

Data class copy function to have the same visibility as constructor

Currently, if you create a data class using a `private` constructor, the automatically generated `copy()` function doesn't have the same visibility. This can cause problems later in your code. In future Kotlin releases, we will introduce the behavior that the default visibility of the `copy()` function is the same as the constructor. This change will be introduced gradually to help you migrate your code as smoothly as possible.

Our migration plan starts with Kotlin 2.0.20, which issues warnings in your code where the visibility will change in the future. For example:

```
// Triggers a warning in 2.0.20
data class PositiveInteger private constructor(val number: Int) {
    companion object {
        fun create(number: Int): PositiveInteger? = if (number > 0) PositiveInteger(number) else null
    }
}

fun main() {
    val positiveNumber = PositiveInteger.create(42) ?: return
    // Triggers a warning in 2.0.20
    val negativeNumber = positiveNumber.copy(number = -1)
    // Warning: Non-public primary constructor is exposed via the generated 'copy()' method of the
'data' class.
    // The generated 'copy()' will change its visibility in future releases.
}
```

For the latest information about our migration plan, see the corresponding issue in YouTrack.

To give you more control over this behavior, in Kotlin 2.0.20 we've introduced two annotations:

- `@ConsistentCopyVisibility` to opt in to the behavior now before we make it the default in a later release.
- `@ExposedCopyVisibility` to opt out of the behavior and suppress warnings at the declaration site. Note that even with this annotation, the compiler still reports warnings when the `copy()` function is called.

If you want to opt in to the new behavior already in 2.0.20 for a whole module rather than in individual classes, you can use the `-Xconsistent-data-class-copy-visibility` compiler option. This option has the same effect as adding the `@ConsistentCopyVisibility` annotation to all data classes in a module.

Phased replacement of context receivers with context parameters

In Kotlin 1.6.20, we introduced context receivers as an Experimental feature. After listening to community feedback, we've decided not to continue with this approach and will take a different direction.

In future Kotlin releases, context receivers will be replaced by context parameters. Context parameters are still in the design phase, and you can find the proposal in the KEEP.

Since the implementation of context parameters requires significant changes to the compiler, we've decided not to support context receivers and context parameters simultaneously. This decision greatly simplifies the implementation and minimizes the risk of unstable behavior.

We understand that context receivers are already being used by a large number of developers. Therefore, we will begin gradually removing support for context receivers. Our migration plan starts with Kotlin 2.0.20, where warnings are issued in your code when context receivers are used with the `-Xcontext-receivers` compiler option. For example:

```
class MyContext

context(MyContext)
// Warning: Experimental context receivers are deprecated and will be superseded by context
parameters.
// Please don't use context receivers. You can either pass parameters explicitly or use members with
extensions.
fun someFunction() {
}
```

This warning will become an error in future Kotlin releases.

If you use context receivers in your code, we recommend that you migrate your code to use either of the following:

- Explicit parameters.

Before	After

`context(ContextReceiverType)`
`fun someFunction() {`
`  contextReceiverMember()`
`}`
	`fun someFunction(explicitContext: ContextReceiverType) {`
	`  explicitContext.contextReceiverMember()`
	`}`

- Extension member functions (if possible).

Before	After

`context(ContextReceiverType)`
`fun contextReceiverMember() = TODO()`
 	
`context(ContextReceiverType)`
`fun someFunction() {`
`  contextReceiverMember()`
`}`
	`class ContextReceiverType {`
	`  fun contextReceiverMember() = TODO()`
	`}`
	
	`fun ContextReceiverType.someFunction() {`
	`  contextReceiverMember()`
	`}`

Alternatively, you can wait until the Kotlin release where context parameters are supported in the compiler. Note that context parameters will initially be introduced as an Experimental feature.

Kotlin Multiplatform

Kotlin 2.0.20 brings improvements to source set management in multiplatform projects as well as deprecates compatibility with some Gradle Java plugins due to recent changes in Gradle.

Static accessors for source sets from the default target hierarchy

Since Kotlin 1.9.20, the default hierarchy template is automatically applied to all Kotlin Multiplatform projects. And for all of the source sets from the default hierarchy template, the Kotlin Gradle plugin provided type-safe accessors. That way, you could finally access source sets for all the specified targets without having to use `by getting` or `by creating` constructs.

Kotlin 2.0.20 aims to improve your IDE experience even further. It now provides static accessors in the `sourceSets {}` block for all the source sets from the default hierarchy template. We believe this change will make accessing source sets by name easier and more predictable.

Each such source set now has a detailed KDoc comment with a sample and a diagnostic message with a warning in case you try to access the source set without declaring the corresponding target first:

```
kotlin {
    jvm()
    linuxX64()
    linuxArm64()
    mingwX64()

    sourceSets {
        commonMain.languageSettings {
            progressiveMode = true
        }

        jvmMain { }
        linuxX64Main { }
        linuxArm64Main { }
        // Warning: accessing source set without registering the target
        iosX64Main { }
    }
}
```

```
public abstract val NamedDomainObjectContainer<KotlinSourceSet>.iosX64Main:
NamedDomainObjectProvider<KotlinSourceSet>
```

Static accessor for the main Kotlin Source Set of iosX64 target. Declare iosX64 target to access this source set. If iosX64 target wasn't declared, accessing this source set will cause a runtime error during configuration time.

Sample:

```
kotlin {
   iosX64() // Target is declared, iosX64Main source set is created

   sourceSets {
     iosX64Main.dependencies {
         // Add iosX64Main dependencies here
     }
   }
}
```

Since: 2.0.20

Accessing the source sets by name

Learn more about the hierarchical project structure in Kotlin Multiplatform.

Deprecated compatibility with Kotlin Multiplatform Gradle plugin and Gradle Java plugins

In Kotlin 2.0.20, we introduce a deprecation warning when you apply the Kotlin Multiplatform Gradle plugin and any of the following Gradle Java plugins to the same project: Java, Java Library, and Application. The warning also appears when another Gradle plugin in your multiplatform project applies a Gradle Java plugin. For example, the Spring Boot Gradle Plugin automatically applies the Application plugin.

We've added this deprecation warning due to fundamental compatibility issues between Kotlin Multiplatform's project model and Gradle's Java ecosystem plugins. Gradle's Java ecosystem plugins currently don't take into account that other plugins may:

- Also publish or compile for the JVM target in a different way than the Java ecosystem plugins.
- Have two different JVM targets in the same project, such as JVM and Android.
- Have a complex multiplatform project structure with potentially multiple non-JVM targets.

Unfortunately, Gradle doesn't currently provide any API to address these issues.

We previously used some workarounds in Kotlin Multiplatform to help with the integration of Java ecosystem plugins. However, these workarounds never truly solved the compatibility issues, and since the release of Gradle 8.8, these workarounds are no longer possible. For more information, see our YouTrack issue.

While we don't yet know exactly how to resolve this compatibility problem, we are committed to continuing support for some form of Java source compilation in your Kotlin Multiplatform projects. At a minimum, we will support the compilation of Java sources and using Gradle's `java-base` plugin within your multiplatform projects.

In the meantime, if you see this deprecation warning in your multiplatform project, we recommend that you:

1. Determine whether you actually need the Gradle Java plugin in your project. If not, consider removing it.
2. Check if the Gradle Java plugin is only used for a single task. If so, you might be able to remove the plugin without much effort. For example, if the task uses a Gradle Java plugin to create a Javadoc JAR file, you can define the Javadoc task manually instead.

Otherwise, if you want to use both the Kotlin Multiplatform Gradle plugin and these Gradle plugins for Java in your multiplatform project, we recommend that you:

1. Create a separate subproject in your multiplatform project.
2. In the separate subproject, apply the Gradle plugin for Java.
3. In the separate subproject, add a dependency on your parent multiplatform project.

> The separate subproject must **not** be a multiplatform project, and you must only use it to set up a dependency on your multiplatform project.

For example, you have a multiplatform project called `my-main-project` and you want to use the Application Gradle plugin to run a JVM application.

Once you've created a subproject, let's call it `subproject-A`, your parent project structure should look like this:

```
.
├── build.gradle.kts
├── settings.gradle
├── subproject-A
    └── build.gradle.kts
    └── src
        └── Main.java
```

In your subproject's `build.gradle.kts` file, apply the Application plugin in the `plugins {}` block:

Kotlin

```
plugins {
    id("application")
}
```

Groovy

```
plugins {
    id('application')
}
```

In your subproject's `build.gradle.kts` file, add a dependency on your parent multiplatform project:

Kotlin

```
dependencies {
    implementation(project(":my-main-project")) // The name of your parent multiplatform project
}
```

Groovy

```
dependencies {
    implementation project(':my-main-project') // The name of your parent multiplatform project
}
```

Your parent project is now set up to work with both plugins.

Kotlin/Native

Kotlin/Native receives improvements in the garbage collector and for calling Kotlin suspending functions from Swift/Objective-C.

Concurrent marking in garbage collector

In Kotlin 2.0.20, the JetBrains team takes another step toward improving Kotlin/Native runtime performance. We've added experimental support for concurrent marking in the garbage collector (GC).

By default, application threads must be paused when GC is marking objects in the heap. This greatly affects the duration of the GC pause time, which is important for the performance of latency-critical applications, such as UI applications built with Compose Multiplatform.

Now, the marking phase of the garbage collection can be run simultaneously with application threads. This should significantly shorten the GC pause time and help improve app responsiveness.

How to enable

The feature is currently Experimental. To enable it, set the following option in your `gradle.properties` file:

```
kotlin.native.binary.gc=cms
```

Please report any problems to our issue tracker YouTrack.

Support for bitcode embedding removed

Starting with Kotlin 2.0.20, the Kotlin/Native compiler no longer supports bitcode embedding. Bitcode embedding was deprecated in Xcode 14 and removed in Xcode 15 for all Apple targets.

Now, the `embedBitcode` parameter for the framework configuration, as well as the `-Xembed-bitcode` and `-Xembed-bitcode-marker` command line arguments are deprecated.

If you still use earlier versions of Xcode but want to upgrade to Kotlin 2.0.20, disable bitcode embedding in your Xcode projects.

Changes to GC performance monitoring with signposts

Kotlin 2.0.0 made it possible to monitor the performance of the Kotlin/Native garbage collector (GC) through Xcode Instruments. Instruments include the signposts tool, which can show GC pauses as events. This comes in handy when checking GC-related freezes in your iOS apps.

The feature was enabled by default, but unfortunately, it sometimes led to crashes when the application was run simultaneously with Xcode Instruments. Starting with Kotlin 2.0.20, it requires an explicit opt-in with the following compiler option:

```
-Xbinary=enableSafepointSignposts=true
```

Learn more about GC performance analysis in the documentation.

Ability to call Kotlin suspending functions from Swift/Objective-C on non-main threads

Previously, Kotlin/Native had a default restriction, limiting the ability to call Kotlin suspending functions from Swift and Objective-C to only the main thread. Kotlin 2.0.20 lifts that limitation, allowing you to run Kotlin `suspend` functions from Swift/Objective-C on any thread.

If you've previously switched the default behavior for non-main threads with the `kotlin.native.binary.objcExportSuspendFunctionLaunchThreadRestriction=none` binary option, you can now remove it from your `gradle.properties` file.

Kotlin/Wasm

In Kotlin 2.0.20, Kotlin/Wasm continues the migration towards named exports and relocates the `@ExperimentalWasmDsl` annotation.

Error in default export usage

As part of the migration towards named exports, a warning message was previously printed to the console when using a default import for Kotlin/Wasm exports in JavaScript.

To fully support named exports, this warning has now been upgraded to an error. If you use a default import, you encounter the following error message:

```
Do not use default import. Use the corresponding named import instead.
```

This change is part of a deprecation cycle to migrate towards named exports. Here's what you can expect during each phase:

- **In version 2.0.0**: A warning message is printed to the console, explaining that exporting entities via default exports is deprecated.
- **In version 2.0.20**: An error occurs, requesting the use of the corresponding named import.
- **In version 2.1.0**: The use of default imports is completely removed.

New location of ExperimentalWasmDsl annotation

Previously, the `@ExperimentalWasmDsl` annotation for WebAssembly (Wasm) features was placed in this location within the Kotlin Gradle plugin:

```
org.jetbrains.kotlin.gradle.targets.js.dsl.ExperimentalWasmDsl
```

In 2.0.20, the `@ExperimentalWasmDsl` annotation has been relocated to:

```
org.jetbrains.kotlin.gradle.ExperimentalWasmDsl
```

The previous location is now deprecated and might lead to build failures with unresolved references.

To reflect the new location of the `@ExperimentalWasmDsl` annotation, update the import statement in your Gradle build scripts. Use an explicit import for the new `@ExperimentalWasmDsl` location:

```
import org.jetbrains.kotlin.gradle.ExperimentalWasmDsl
```

Alternatively, remove this star import statement from the old package:

```
import org.jetbrains.kotlin.gradle.targets.js.dsl.*
```

Kotlin/JS

Kotlin/JS introduces some Experimental features to support static members in JavaScript and to create Kotlin collections from JavaScript.

Support for using Kotlin static members in JavaScript

> This feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Starting with Kotlin 2.0.20, you can use the `@JsStatic` annotation. It works similarly to @JvmStatic and instructs the compiler to generate additional static methods for the target declaration. This helps you use static members from your Kotlin code directly in JavaScript.

You can use the `@JsStatic` annotation for functions defined in named objects, as well as in companion objects declared inside classes and interfaces. The compiler generates both a static method of the object and an instance method in the object itself. For example:

```
class C {
    companion object {
        @JsStatic
        fun callStatic() {}
        fun callNonStatic() {}
    }
}
```

Now, `callStatic()` is static in JavaScript while `callNonStatic()` is not:

```
C.callStatic();              // Works, accessing the static function
C.callNonStatic();           // Error, not a static function in the generated JavaScript
C.Companion.callStatic();    // Instance method remains
C.Companion.callNonStatic(); // The only way it works
```

It's also possible to apply the `@JsStatic` annotation to a property of an object or a companion object, making its getter and setter methods static members in that object or the class containing the companion object.

Ability to create Kotlin collections from JavaScript

> This feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 2.0.0 introduced the ability to export Kotlin collections to JavaScript (and TypeScript). Now, the JetBrains team is taking another step to improve collection interoperability. Starting with Kotlin 2.0.20, it's possible to create Kotlin collections directly from the JavaScript/TypeScript side.

You can create Kotlin collections from JavaScript and pass them as arguments to the exported constructors or functions. As soon as you mention a collection inside an exported declaration, Kotlin generates a factory for the collection that is available in JavaScript/TypeScript.

Take a look at the following exported function:

```
// Kotlin
@JsExport
fun consumeMutableMap(map: MutableMap<String, Int>)
```

Since the `MutableMap` collection is mentioned, Kotlin generates an object with a factory method available from JavaScript/TypeScript. This factory method then creates a `MutableMap` from a JavaScript `Map`:

```
// JavaScript
import { consumeMutableMap } from "an-awesome-kotlin-module"
import { KtMutableMap } from "an-awesome-kotlin-module/kotlin-kotlin-stdlib"

consumeMutableMap(
    KtMutableMap.fromJsMap(new Map([["First", 1], ["Second", 2]]))
)
```

This feature is available for the `Set`, `Map`, and `List` Kotlin collection types and their mutable counterparts.

Gradle

Kotlin 2.0.20 is fully compatible with Gradle 6.8.3 through 8.6. Gradle 8.7 and 8.8 are also supported, with only one exception: If you use the Kotlin Multiplatform Gradle plugin, you may see deprecation warnings in your multiplatform projects calling the `withJava()` function in the JVM target. We plan to fix this issue as soon as possible.

For more information, see the issue in YouTrack.

You can also use Gradle versions up to the latest Gradle release, but if you do, keep in mind that you might encounter deprecation warnings or some new Gradle features might not work.

This version brings changes such as beginning the deprecation process for the old incremental compilation approach based on JVM history files, as well as a new way of sharing JVM artifacts between projects.

Deprecated incremental compilation based on JVM history files

In Kotlin 2.0.20, the incremental compilation approach based on JVM history files is deprecated in favor of the new incremental compilation approach that has been enabled by default since Kotlin 1.8.20.

The incremental compilation approach based on JVM history files suffered from limitations, such as not working with Gradle's build cache and not supporting compilation avoidance. In contrast, the new incremental compilation approach overcomes these limitations and has performed well since its introduction.

Given that the new incremental compilation approach has been used by default for the last two major Kotlin releases, the `kotlin.incremental.useClasspathSnapshot` Gradle property is deprecated in Kotlin 2.0.20. Therefore, if you use it to opt out, you will see a deprecation warning.

Option to share JVM artifacts between projects as class files

> This feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack. Opt-in is required (see details below).

In Kotlin 2.0.20, we introduce a new approach that changes the way the outputs of Kotlin/JVM compilations, such as JAR files, are shared between projects. With this approach, Gradle's `apiElements` configuration now has a secondary variant that provides access to the directory containing compiled `.class` files. When configured, your project uses this directory instead of requesting the compressed JAR artifact during compilation. This reduces the number of times JAR files are compressed and decompressed, especially for incremental builds.

Our testing shows that this new approach can provide build performance improvements for Linux and macOS hosts. However, on Windows hosts, we have seen a degradation in performance due to how Windows handles I/O operations when working with files.

To try this new approach, add the following property to your `gradle.properties` file:

```
kotlin.jvm.addClassesVariant=true
```

By default, this property is set to `false` and the `apiElements` variant in Gradle requests the compressed JAR artifact.

> Gradle has a related property that you can use in your Java-only projects to only expose the compressed JAR artifact during compilation **instead** of the directories containing compiled `.class` files:
>
> ```
> org.gradle.java.compile-classpath-packaging=true
> ```
>
> For more information on this property and its purpose, see Gradle's documentation on the Significant build performance drop on Windows for huge multi-projects.

We would appreciate your feedback on this new approach. Have you noticed any performance improvements while using it? Let us know by adding a comment in YouTrack.

Aligned dependency behavior of Kotlin Gradle plugin with java-test-fixtures plugin

Prior to Kotlin 2.0.20, if you used the `java-test-fixtures` plugin in your project, there was a difference between Gradle and the Kotlin Gradle plugin in how dependencies were propagated.

The Kotlin Gradle plugin propagated dependencies:

- From the `java-test-fixtures` plugin's `implementation` and `api` dependency types to the `test` source set compilation classpath.
- From the main source set's `implementation` and `api` dependency types to the `java-test-fixtures` plugin's source set compilation classpath.

However, Gradle only propagated dependencies in the `api` dependency types.

This difference in behavior led to some projects finding resource files multiple times in the classpath.

As of Kotlin 2.0.20, the Kotlin Gradle plugin's behavior is aligned with Gradle's `java-test-fixtures` plugin so this problem no longer occurs for this or other Gradle plugins.

As a result of this change, some dependencies in the `test` and `testFixtures` source sets may no longer be accessible. If this happens, either change the dependency declaration type from `implementation` to `api` or add a new dependency declaration on the affected source set.

Added task dependency for rare cases when the compile task lacks one on an artifact

Prior to 2.0.20, we found that there were scenarios where a compile task was missing a task dependency for one of its artifact inputs. This meant that the result of the dependent compile task was unstable, as sometimes the artifact had been generated in time, but sometimes, it hadn't.

To fix this issue, the Kotlin Gradle plugin now automatically adds the required task dependency in these scenarios.

In very rare cases, we've found that this new behavior can cause a circular dependency error. For example, if you have multiple compilations where one compilation can see all internal declarations of the other, and the generated artifact relies on the output of both compilation tasks, you could see an error like:

```
FAILURE: Build failed with an exception.

What went wrong:
Circular dependency between the following tasks:
:lib:compileKotlinJvm
--- :lib:jvmJar
     \--- :lib:compileKotlinJvm (*)
(*) - details omitted (listed previously)
```

To fix this circular dependency error, we've added a Gradle property: `archivesTaskOutputAsFriendModule`.

By default, this property is set to `true` to track the task dependency. To disable the use of the artifact in the compilation task, so that no task dependency is required, add the following in your `gradle.properties` file:

```
kotlin.build.archivesTaskOutputAsFriendModule=false
```

For more information, see the issue in YouTrack.

Compose compiler

In Kotlin 2.0.20, the Compose compiler gets a few improvements.

Fix for the unnecessary recompositions issue introduced in 2.0.0

Compose compiler 2.0.0 has an issue where it sometimes incorrectly infers the stability of types in multiplatform projects with non-JVM targets. This can lead to unnecessary (or even endless) recompositions. We strongly recommended updating your Compose apps made for Kotlin 2.0.0 to version 2.0.10 or newer.

If your app is built with Compose compiler 2.0.10 or newer but uses dependencies built with version 2.0.0, these older dependencies may still cause recomposition issues. To prevent this, update your dependencies to versions built with the same Compose compiler as your app.

New way to configure compiler options

We've introduced a new option configuration mechanism to avoid the churn of top-level parameters. It's harder for the Compose compiler team to test things out by creating or removing top-level entries for the `composeCompiler {}` block. So, options such as strong skipping mode and non-skipping group optimizations are now enabled through the `featureFlags` property. This property will be used to test new Compose compiler options that will eventually become default.

This change has also been applied to the Compose compiler Gradle plugin. To configure feature flags going forward, use the following syntax (this code will flip all of the default values):

```
composeCompiler {
    featureFlags = setOf(
        ComposeFeatureFlag.IntrinsicRemember.disabled(),
        ComposeFeatureFlag.OptimizeNonSkippingGroups,
        ComposeFeatureFlag.StrongSkipping.disabled()
    )
}
```

Or, if you are configuring the Compose compiler directly, use the following syntax:

```
-P plugin:androidx.compose.compiler.plugins.kotlin:featureFlag=IntrinsicRemember
```

The `enableIntrinsicRemember`, `enableNonSkippingGroupOptimization`, and `enableStrongSkippingMode` properties have been therefore deprecated.

We would appreciate any feedback you have on this new approach in YouTrack.

Strong skipping mode enabled by default

Strong skipping mode for the Compose compiler is now enabled by default.

Strong skipping mode is a Compose compiler configuration option that changes the rules for what composables can be skipped. With strong skipping mode enabled, composables with unstable parameters can now also be skipped. Strong skipping mode also automatically remembers lambdas used in composable functions, so you should no longer need to wrap your lambdas with `remember` to avoid recomposition.

For more details, see the strong skipping mode documentation.

Composition trace markers enabled by default

The `includeTraceMarkers` option is now set to `true` by default in the Compose compiler Gradle plugin to match the default value in the compiler plugin. This allows you to see composable functions in the Android Studio system trace profiler. For details about composition tracing, see this Android Developers blog post.

Non-skipping group optimizations

This release includes a new compiler option: when enabled, non-skippable and non-restartable composable functions will no longer generate a group around the body of the composable. This leads to fewer allocations and thus to improved performance. This option is experimental and disabled by default but can be enabled with the feature flag `OptimizeNonSkippingGroups` as shown above.

This feature flag is now ready for wider testing. Any issues found when enabling the feature can be filed on the Google issue tracker.

Support for default parameters in abstract composable functions

You can now add default parameters to abstract composable functions.

Previously, the Compose compiler would report an error when attempting to do this even though it is valid Kotlin code. We've now added support for this in the Compose compiler, and the restriction has been removed. This is especially useful for including default `Modifier` values:

```
abstract class Composables {
    @Composable
    abstract fun Composable(modifier: Modifier = Modifier)
}
```

Default parameters for open composable functions are still restricted in 2.0.20. This restriction will be addressed in future releases.

Standard library

The standard library now supports universally unique identifiers as an Experimental feature and includes some changes to Base64 decoding.

Support for UUIDs in the common Kotlin standard library

> This feature is Experimental. To opt in, use the `@ExperimentalUuidApi` annotation or the compiler option `-opt-in=kotlin.uuid.ExperimentalUuidApi`.

Kotlin 2.0.20 introduces a class for representing UUIDs (universally unique identifiers) in the common Kotlin standard library to address the challenge of uniquely identifying items.

Additionally, this feature provides APIs for the following UUID-related operations:

- Generating UUIDs.
- Parsing UUIDs from and formatting them to their string representations.
- Creating UUIDs from specified 128-bit values.
- Accessing the 128 bits of a UUID.

The following code example demonstrates these operations:

```
// Constructs a byte array for UUID creation
val byteArray = byteArrayOf(
    0x55, 0x0E, 0x84.toByte(), 0x00, 0xE2.toByte(), 0x9B.toByte(), 0x41, 0xD4.toByte(),
    0xA7.toByte(), 0x16, 0x44, 0x66, 0x55, 0x44, 0x00, 0x00
)

val uuid1 = Uuid.fromByteArray(byteArray)
val uuid2 = Uuid.fromULongs(0x550E8400E29B41D4uL, 0xA716446655440000uL)
val uuid3 = Uuid.parse("550e8400-e29b-41d4-a716-446655440000")

println(uuid1)
// 550e8400-e29b-41d4-a716-446655440000
println(uuid1 == uuid2)
// true
println(uuid2 == uuid3)
// true

// Accesses UUID bits
val version = uuid1.toLongs { mostSignificantBits, _ ->
    ((mostSignificantBits shr 12) and 0xF).toInt()
}
println(version)
// 4

// Generates a random UUID
val randomUuid = Uuid.random()

println(uuid1 == randomUuid)
// false
```

To maintain compatibility with APIs that use `java.util.UUID`, there are two extension functions in Kotlin/JVM for converting between `java.util.UUID` and `kotlin.uuid.Uuid`: `.toJavaUuid()` and `.toKotlinUuid()`. For example:

```
val kotlinUuid = Uuid.parseHex("550e8400e29b41d4a716446655440000")
// Converts Kotlin UUID to java.util.UUID
val javaUuid = kotlinUuid.toJavaUuid()

val javaUuid = java.util.UUID.fromString("550e8400-e29b-41d4-a716-446655440000")
// Converts Java UUID to kotlin.uuid.Uuid
val kotlinUuid = javaUuid.toKotlinUuid()
```

This feature and the provided APIs simplify multiplatform software development by allowing code sharing among multiple platforms. UUIDs are also ideal in environments where generating unique identifiers is difficult.

Some example use cases involving UUIDs include:

- Assigning unique IDs to database records.
- Generating web session identifiers.
- Any scenario requiring unique identification or tracking.

Support for minLength in HexFormat

> The `HexFormat` class and its properties are Experimental. To opt in, use the `@OptIn(ExperimentalStdlibApi::class)` annotation or the compiler option `-opt-in=kotlin.ExperimentalStdlibApi`.

Kotlin 2.0.20 adds a new `minLength` property to the `NumberHexFormat` class, accessed through `HexFormat.number`. This property lets you specify the minimum number of digits in hexadecimal representations of numeric values, enabling padding with zeros to meet the required length. Additionally, leading zeros can be trimmed using the `removeLeadingZeros` property:

```
fun main() {
    println(93.toHexString(HexFormat {
        number.minLength = 4
        number.removeLeadingZeros = true
    }))
    // "005d"
}
```

The `minLength` property does not affect parsing. However, parsing now allows hex strings to have more digits than the type's width if the extra leading digits are zeros.

Changes to the Base64's decoder behavior

The `Base64` class and its related features are Experimental. To opt in, use the `@OptIn(ExperimentalEncodingApi::class)` annotation or the compiler option `-opt-in=kotlin.io.encoding.ExperimentalEncodingApi`.

Two changes were introduced to the Base64 decoder's behavior in Kotlin 2.0.20:

- The Base64 decoder now requires padding
- A `withPadding` function has been added for padding configuration

The Base64 decoder now requires padding

The Base64 encoder now adds padding by default, and the decoder requires padding and prohibits non-zero pad bits when decoding.

withPadding function for padding configuration

A new `.withPadding()` function has been introduced to give users control over the padding behavior of Base64 encoding and decoding:

```
val base64 = Base64.UrlSafe.withPadding(Base64.PaddingOption.ABSENT_OPTIONAL)
```

This function enables the creation of `Base64` instances with different padding options:

`PaddingOption`	On encode	On decode
`PRESENT`	Add padding	Padding is required
`ABSENT`	Omit padding	No padding allowed
`PRESENT_OPTIONAL`	Add padding	Padding is optional

PaddingOption	On encode	On decode
ABSENT_OPTIONAL	Omit padding	Padding is optional

You can create `Base64` instances with different padding options and use them to encode and decode data:

```
import kotlin.io.encoding.Base64
import kotlin.io.encoding.ExperimentalEncodingApi

@OptIn(ExperimentalEncodingApi::class)
fun main() {
    // Example data to encode
    val data = "fooba".toByteArray()

    // Creates a Base64 instance with URL-safe alphabet and PRESENT padding
    val base64Present = Base64.UrlSafe.withPadding(Base64.PaddingOption.PRESENT)
    val encodedDataPresent = base64Present.encode(data)
    println("Encoded data with PRESENT padding: $encodedDataPresent")
    // Encoded data with PRESENT padding: Zm9vYmE=

    // Creates a Base64 instance with URL-safe alphabet and ABSENT padding
    val base64Absent = Base64.UrlSafe.withPadding(Base64.PaddingOption.ABSENT)
    val encodedDataAbsent = base64Absent.encode(data)
    println("Encoded data with ABSENT padding: $encodedDataAbsent")
    // Encoded data with ABSENT padding: Zm9vYmE

    // Decodes the data back
    val decodedDataPresent = base64Present.decode(encodedDataPresent)
    println("Decoded data with PRESENT padding: ${String(decodedDataPresent)}")
    // Decoded data with PRESENT padding: fooba

    val decodedDataAbsent = base64Absent.decode(encodedDataAbsent)
    println("Decoded data with ABSENT padding: ${String(decodedDataAbsent)}")
    // Decoded data with ABSENT padding: fooba
}
```

Documentation updates

The Kotlin documentation has received some notable changes:

- Improved Standard input page - Learn how to use Java Scanner and `readln()`.
- Improved K2 compiler migration guide - Learn about performance improvements, compatibility with Kotlin libraries and what to do with your custom compiler plugins.
- Improved Exceptions page - Learn about exceptions, how to throw and catch them.
- Improved Test code using JUnit in JVM - tutorial - Learn how to create tests using JUnit.
- Improved Interoperability with Swift/Objective-C page - Learn how to use Kotlin declarations in Swift/Objective-C code and Objective-C declarations in Kotlin code.
- Improved Swift package export setup page - Learn how to set up Kotlin/Native output that can be consumed by a Swift package manager dependency.

Install Kotlin 2.0.20

Starting from IntelliJ IDEA 2023.3 and Android Studio Iguana (2023.2.1) Canary 15, the Kotlin plugin is distributed as a bundled plugin included in your IDE. This means that you can't install the plugin from JetBrains Marketplace anymore.

To update to the new Kotlin version, change the Kotlin version to 2.0.20 in your build scripts.

What's new in Kotlin 2.0.0

Released: May 21, 2024

The Kotlin 2.0.0 release is out and the new Kotlin K2 compiler is Stable! Additionally, here are some other highlights:

- New Compose compiler Gradle plugin
- Generation of lambda functions using invokedynamic
- The kotlinx-metadata-jvm library is now Stable
- Monitoring GC performance in Kotlin/Native with signposts on Apple platforms
- Resolving conflicts in Kotlin/Native with Objective-C methods
- Support for named export in Kotlin/Wasm
- Support for unsigned primitive types in functions with @JsExport in Kotlin/Wasm
- Optimize production builds by default using Binaryen
- New Gradle DSL for compiler options in multiplatform projects
- Stable replacement of the enum class values generic function
- Stable AutoCloseable interface

Kotlin 2.0 is a huge milestone for the JetBrains team. This release was the center of KotlinConf 2024. Check out the opening keynote, where we announced exciting updates and addressed the recent work on the Kotlin language:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support Kotlin 2.0.0 are bundled in the latest IntelliJ IDEA and Android Studio. You don't need to update the Kotlin plugin in your IDE. All you need to do is to change the Kotlin version to Kotlin 2.0.0 in your build scripts.

- For details about IntelliJ IDEA's support for the Kotlin K2 compiler, see Support in IDEs.
- For more details about IntelliJ IDEA's support for Kotlin, see Kotlin releases.

Kotlin K2 compiler

The road to the K2 compiler has been a long one, but now the JetBrains team is finally ready to announce its stabilization. In Kotlin 2.0.0, the new Kotlin K2 compiler is used by default and it is Stable for all target platforms: JVM, Native, Wasm, and JS. The new compiler brings major performance improvements, speeds up new language feature development, unifies all platforms that Kotlin supports, and provides a better architecture for multiplatform projects.

The JetBrains team has ensured the quality of the new compiler by successfully compiling 10 million lines of code from selected user and internal projects. 18,000 developers were involved in the stabilization process, testing the new K2 compiler across a total of 80,000 projects and reporting any problems they found.

To help make the migration process to the new compiler as smooth as possible, we've created a K2 compiler migration guide. This guide explains the many benefits of the compiler, highlights any changes you might encounter, and describes how to roll back to the previous version if necessary.

In a blog post, we explored the performance of the K2 compiler in different projects. Check it out if you'd like to see real data on how the K2 compiler performs and find instructions on how to collect performance benchmarks from your own projects.

You can also watch this talk from KotlinConf 2024, where Michail Zarečenskij, the lead language designer, discusses the feature evolution in Kotlin and the K2 compiler:

Watch video online.

Current K2 compiler limitations

Enabling K2 in your Gradle project comes with certain limitations that can affect projects using Gradle versions below 8.3 in the following cases:

- Compilation of source code from `buildSrc`.
- Compilation of Gradle plugins in included builds.
- Compilation of other Gradle plugins if they are used in projects with Gradle versions below 8.3.
- Building Gradle plugin dependencies.

If you encounter any of the problems mentioned above, you can take the following steps to address them:

- Set the language version for `buildSrc`, any Gradle plugins, and their dependencies:

```
kotlin {
    compilerOptions {
        languageVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9)
        apiVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9)
    }
}
```

> If you configure language and API versions for specific tasks, these values will override the values set by the `compilerOptions` extension. In this case, language and API versions should not be higher than 1.9.

- Update the Gradle version in your project to 8.3 or later.

Smart cast improvements

The Kotlin compiler can automatically cast an object to a type in specific cases, saving you the trouble of having to explicitly cast it yourself. This is called smart casting. The Kotlin K2 compiler now performs smart casts in even more scenarios than before.

In Kotlin 2.0.0, we've made improvements related to smart casts in the following areas:

- Local variables and further scopes
- Type checks with logical `or` operator
- Inline functions
- Properties with function types
- Exception handling
- Increment and decrement operators

Local variables and further scopes

Previously, if a variable was evaluated as not `null` within an `if` condition, the variable would be smart-cast. Information about this variable would then be shared further within the scope of the `if` block.

However, if you declared the variable **outside** the `if` condition, no information about the variable would be available within the `if` condition, so it couldn't be smart-cast. This behavior was also seen with `when` expressions and `while` loops.

From Kotlin 2.0.0, if you declare a variable before using it in your `if`, `when`, or `while` condition, then any information collected by the compiler about the variable will be accessible in the corresponding block for smart-casting.

This can be useful when you want to do things like extract boolean conditions into variables. Then, you can give the variable a meaningful name, which will improve your code readability and make it possible to reuse the variable later in your code. For example:

```
class Cat {
    fun purr() {
        println("Purr purr")
    }
}

fun petAnimal(animal: Any) {
    val isCat = animal is Cat
    if (isCat) {
        // In Kotlin 2.0.0, the compiler can access
        // information about isCat, so it knows that
        // animal was smart-cast to the type Cat.
        // Therefore, the purr() function can be called.
        // In Kotlin 1.9.20, the compiler doesn't know
        // about the smart cast, so calling the purr()
        // function triggers an error.
        animal.purr()
    }
}

fun main() {
    val kitty = Cat()
    petAnimal(kitty)
    // Purr purr
}
```

Type checks with logical or operator

In Kotlin 2.0.0, if you combine type checks for objects with an `or` operator (`||`), a smart cast is made to their closest common supertype. Before this change, a smart cast was always made to the `Any` type.

In this case, you still had to manually check the object type afterward before you could access any of its properties or call its functions. For example:

```
interface Status {
    fun signal() {}
}

interface Ok : Status
interface Postponed : Status
interface Declined : Status

fun signalCheck(signalStatus: Any) {
    if (signalStatus is Postponed || signalStatus is Declined) {
        // signalStatus is smart-cast to a common supertype Status
        signalStatus.signal()
        // Prior to Kotlin 2.0.0, signalStatus is smart cast
        // to type Any, so calling the signal() function triggered an
        // Unresolved reference error. The signal() function can only
        // be called successfully after another type check:

        // check(signalStatus is Status)
        // signalStatus.signal()
    }
}
```

The common supertype is an **approximation** of a union type. Union types are not supported in Kotlin.

Inline functions

In Kotlin 2.0.0, the K2 compiler treats inline functions differently, allowing it to determine in combination with other compiler analyses whether it's safe to smart-cast.

Specifically, inline functions are now treated as having an implicit `callsInPlace` contract. This means that any lambda functions passed to an inline function are called in place. Since lambda functions are called in place, the compiler knows that a lambda function can't leak references to any variables contained within its function body.

The compiler uses this knowledge along with other compiler analyses to decide whether it's safe to smart-cast any of the captured variables. For example:

```
interface Processor {
    fun process()
}

inline fun inlineAction(f: () -> Unit) = f()

fun nextProcessor(): Processor? = null

fun runProcessor(): Processor? {
    var processor: Processor? = null
    inlineAction {
        // In Kotlin 2.0.0, the compiler knows that processor
        // is a local variable, and inlineAction() is an inline function, so
        // references to processor can't be leaked. Therefore, it's safe
        // to smart-cast processor.

        // If processor isn't null, processor is smart-cast
        if (processor ≠ null) {
            // The compiler knows that processor isn't null, so no safe call
            // is needed
            processor.process()

            // In Kotlin 1.9.20, you have to perform a safe call:
            // processor?.process()
        }

        processor = nextProcessor()
    }

    return processor
}
```

Properties with function types

In previous versions of Kotlin, there was a bug that meant that class properties with a function type weren't smart-cast. We fixed this behavior in Kotlin 2.0.0 and the K2 compiler. For example:

```
class Holder(val provider: (() -> Unit)?) {
    fun process() {
        // In Kotlin 2.0.0, if provider isn't null, then
        // provider is smart-cast
        if (provider != null) {
            // The compiler knows that provider isn't null
            provider()

            // In 1.9.20, the compiler doesn't know that provider isn't
            // null, so it triggers an error:
            // Reference has a nullable type '(() -> Unit)?', use explicit '?.invoke()' to make a
function-like call instead
        }
    }
}
```

This change also applies if you overload your `invoke` operator. For example:

```
interface Provider {
    operator fun invoke()
}

interface Processor : () -> String

class Holder(val provider: Provider?, val processor: Processor?) {
    fun process() {
        if (provider != null) {
            provider()
            // In 1.9.20, the compiler triggers an error:
            // Reference has a nullable type 'Provider?' use explicit '?.invoke()' to make a function-
like call instead
        }
    }
}
```

Exception handling

In Kotlin 2.0.0, we've made improvements to exception handling so that smart cast information can be passed on to `catch` and `finally` blocks. This change makes your code safer as the compiler keeps track of whether your object has a nullable type. For example:

```
fun testString() {
    var stringInput: String? = null
    // stringInput is smart-cast to String type
    stringInput = ""
    try {
        // The compiler knows that stringInput isn't null
        println(stringInput.length)
        // 0

        // The compiler rejects previous smart cast information for
        // stringInput. Now stringInput has the String? type.
        stringInput = null

        // Trigger an exception
        if (2 > 1) throw Exception()
        stringInput = ""
    } catch (exception: Exception) {
        // In Kotlin 2.0.0, the compiler knows stringInput
        // can be null, so stringInput stays nullable.
        println(stringInput?.length)
        // null

        // In Kotlin 1.9.20, the compiler says that a safe call isn't
        // needed, but this is incorrect.
    }
}

fun main() {
    testString()
}
```

Increment and decrement operators

Prior to Kotlin 2.0.0, the compiler didn't understand that the type of an object can change after using an increment or decrement operator. As the compiler couldn't accurately track the object type, your code could lead to unresolved reference errors. In Kotlin 2.0.0, this has been fixed:

```
interface Rho {
    operator fun inc(): Sigma = TODO()
}

interface Sigma : Rho {
    fun sigma() = Unit
}

interface Tau {
    fun tau() = Unit
}

fun main(input: Rho) {
    var unknownObject: Rho = input

    // Check if unknownObject inherits from the Tau interface
    // Note, it's possible that unknownObject inherits from both
    // Rho and Tau interfaces.
    if (unknownObject is Tau) {

        // Use the overloaded inc() operator from interface Rho.
        // In Kotlin 2.0.0, the type of unknownObject is smart-cast to
        // Sigma.
        ++unknownObject

        // In Kotlin 2.0.0, the compiler knows unknownObject has type
        // Sigma, so the sigma() function can be called successfully.
        unknownObject.sigma()

        // In Kotlin 1.9.20, the compiler doesn't perform a smart cast
        // when inc() is called so the compiler still thinks that
        // unknownObject has type Tau. Calling the sigma() function
        // throws a compile-time error.

        // In Kotlin 2.0.0, the compiler knows unknownObject has type
        // Sigma, so calling the tau() function throws a compile-time
        // error.
        unknownObject.tau()
        // Unresolved reference 'tau'

        // In Kotlin 1.9.20, since the compiler mistakenly thinks that
        // unknownObject has type Tau, the tau() function can be called,
        // but it throws a ClassCastException.
    }
}
```

Kotlin Multiplatform improvements

In Kotlin 2.0.0, we've made improvements in the K2 compiler related to Kotlin Multiplatform in the following areas:

- Separation of common and platform sources during compilation
- Different visibility levels of expected and actual declarations

Separation of common and platform sources during compilation

Previously, the design of the Kotlin compiler prevented it from keeping common and platform source sets separate at compile time. As a consequence, common code could access platform code, which resulted in different behavior between platforms. In addition, some compiler settings and dependencies from common code used to leak into platform code.

In Kotlin 2.0.0, our implementation of the new Kotlin K2 compiler included a redesign of the compilation scheme to ensure strict separation between common and platform source sets. This change is most noticeable when you use expected and actual functions. Previously, it was possible for a function call in your common code to resolve to a function in platform code. For example:

Common code

```
fun foo(x: Any) = println("common foo")

fun exampleFunction() {
    foo(42)
}
```

Platform code

```
// JVM
fun foo(x: Int) = println("platform foo")

// JavaScript
// There is no foo() function overload
// on the JavaScript platform
```

In this example, the common code has different behavior depending on which platform it is run on:

- On the JVM platform, calling the `foo()` function in the common code results in the `foo()` function from the platform code being called as `platform foo`.
- On the JavaScript platform, calling the `foo()` function in the common code results in the `foo()` function from the common code being called as `common foo`, as there is no such function available in the platform code.

In Kotlin 2.0.0, common code doesn't have access to platform code, so both platforms successfully resolve the `foo()` function to the `foo()` function in the common code: `common foo`.

In addition to the improved consistency of behavior across platforms, we also worked hard to fix cases where there was conflicting behavior between IntelliJ IDEA or Android Studio and the compiler. For instance, when you used expected and actual classes, the following would happen:

Common code

```
expect class Identity {
    fun confirmIdentity(): String
}

fun common() {
    // Before 2.0.0,
    // it triggers an IDE-only error
    Identity().confirmIdentity()
    // RESOLUTION_TO_CLASSIFIER : Expected
class
    // Identity has no default constructor.
}
```

Platform code

```
actual class Identity {
    actual fun confirmIdentity() = "expect class
fun: jvm"
}
```

In this example, the expected class `Identity` has no default constructor, so it can't be called successfully in common code. Previously, an error was only reported by the IDE, but the code still compiled successfully on the JVM. However, now the compiler correctly reports an error:

```
Expected class 'expect class Identity : Any' does not have default constructor
```

When resolution behavior doesn't change

We're still in the process of migrating to the new compilation scheme, so the resolution behavior is still the same when you call functions that aren't within the same source set. You'll notice this difference mainly when you use overloads from a multiplatform library in your common code.

Suppose you have a library, which has two `whichFun()` functions with different signatures:

```
// Example library

// MODULE: common
fun whichFun(x: Any) = println("common function")

// MODULE: JVM
fun whichFun(x: Int) = println("platform function")
```

If you call the `whichFun()` function in your common code, the function that has the most relevant argument type in the library is resolved:

```
// A project that uses the example library for the JVM target

// MODULE: common
fun main() {
    whichFun(2)
    // platform function
}
```

In comparison, if you declare the overloads for `whichFun()` within the same source set, the function from the common code will be resolved because your code doesn't have access to the platform-specific version:

```
// Example library isn't used

// MODULE: common
fun whichFun(x: Any) = println("common function")

fun main() {
    whichFun(2)
    // common function
}

// MODULE: JVM
fun whichFun(x: Int) = println("platform function")
```

Similar to multiplatform libraries, since the `commonTest` module is in a separate source set, it also still has access to platform-specific code. Therefore, the resolution of calls to functions in the `commonTest` module exhibits the same behavior as in the old compilation scheme.

In the future, these remaining cases will be more consistent with the new compilation scheme.

Different visibility levels of expected and actual declarations

Before Kotlin 2.0.0, if you used expected and actual declarations in your Kotlin Multiplatform project, they had to have the same visibility level. Kotlin 2.0.0 now also supports different visibility levels but **only** if the actual declaration is *more* permissive than the expected declaration. For example:

```
expect internal class Attribute // Visibility is internal
actual class Attribute          // Visibility is public by default,
                                // which is more permissive
```

Similarly, if you are using a type alias in your actual declaration, the visibility of the **underlying type** should be the same or more permissive than the expected declaration. For example:

```
expect internal class Attribute                 // Visibility is internal
internal actual typealias Attribute = Expanded

class Expanded                                  // Visibility is public by default,
                                                // which is more permissive
```

Compiler plugins support

Currently, the Kotlin K2 compiler supports the following Kotlin compiler plugins:

- `all-open`
- AtomicFU
- `jvm-abi-gen`
- `js-plain-objects`
- kapt
- Lombok
- `no-arg`
- Parcelize
- SAM with receiver
- serialization
- Power-assert

In addition, the Kotlin K2 compiler supports:

- The Jetpack Compose compiler plugin 2.0.0, which was moved into the Kotlin repository.
- The Kotlin Symbol Processing (KSP) plugin since KSP2.

If you use any additional compiler plugins, check their documentation to see if they are compatible with K2.

Experimental Kotlin Power-assert compiler plugin

The Kotlin Power-assert plugin is Experimental. It may be changed at any time.

Kotlin 2.0.0 introduces an experimental Power-assert compiler plugin. This plugin improves the experience of writing tests by including contextual information in failure messages, making debugging easier and more efficient.

Developers often need to use complex assertion libraries to write effective tests. The Power-assert plugin simplifies this process by automatically generating failure messages that include intermediate values of the assertion expression. This helps developers quickly understand why a test failed.

When an assertion fails in a test, the improved error message shows the values of all variables and sub-expressions within the assertion, making it clear which part of the condition caused the failure. This is particularly useful for complex assertions where multiple conditions are checked.

To enable the plugin in your project, configure it in your `build.gradle(.kts)` file:

Kotlin

```
plugins {
    kotlin("multiplatform") version "2.0.0"
    kotlin("plugin.power-assert") version "2.0.0"
}

powerAssert {
    functions = listOf("kotlin.assert", "kotlin.test.assertTrue")
}
```

Groovy

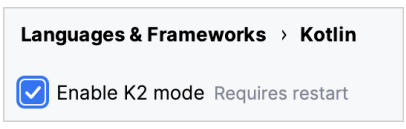
```
plugins {
    id 'org.jetbrains.kotlin.multiplatform' version '2.0.0'
    id 'org.jetbrains.kotlin.plugin.power-assert' version '2.0.0'
}

powerAssert {
    functions = ["kotlin.assert", "kotlin.test.assertTrue"]
}
```

Learn more about the Kotlin Power-assert plugin in the documentation.

How to enable the Kotlin K2 compiler

Starting with Kotlin 2.0.0, the Kotlin K2 compiler is enabled by default. No additional actions are required.



Try the Kotlin K2 compiler in Kotlin Playground

Kotlin Playground supports the 2.0.0 release. Check it out!

Support in IDEs

By default, IntelliJ IDEA and Android Studio still use the previous compiler for code analysis, code completion, highlighting, and other IDE-related features. To get the full Kotlin 2.0 experience in your IDE, enable K2 mode.

In your IDE, go to **Settings** | **Languages & Frameworks** | **Kotlin** and select the **Enable K2 mode** option. The IDE will analyze your code using its K2 mode.

Enable K2 mode

After enabling K2 mode, you may notice differences in IDE analysis due to changes in compiler behavior. Learn how the new K2 compiler differs from the previous one in our migration guide.

- Learn more about K2 mode in our blog.
- We are actively collecting feedback about K2 mode, so please share your thoughts in our public Slack channel.

Leave your feedback on the new K2 compiler

We would appreciate any feedback you may have!

- Report any problems you face with the new K2 compiler in our issue tracker.
- Enable the "Send usage statistics" option to allow JetBrains to collect anonymous data about K2 usage.

Kotlin/JVM

Starting with version 2.0.0, the compiler can generate classes containing Java 22 bytecode. This version also brings the following changes:

- Generation of lambda functions using invokedynamic
- The kotlinx-metadata-jvm library is now Stable

Generation of lambda functions using invokedynamic

Kotlin 2.0.0 introduces a new default method for generating lambda functions using `invokedynamic`. This change reduces the binary sizes of applications compared to the traditional anonymous class generation.

Since the first version, Kotlin has generated lambdas as anonymous classes. However, starting from Kotlin 1.5.0, the option for `invokedynamic` generation has been available by using the `-Xlambdas=indy` compiler option. In Kotlin 2.0.0, `invokedynamic` has become the default method for lambda generation. This method produces lighter binaries and aligns Kotlin with JVM optimizations, ensuring applications benefit from ongoing and future improvements in JVM performance.

Currently, it has three limitations compared to ordinary lambda compilation:

- A lambda compiled into `invokedynamic` is not serializable.
- Experimental `reflect()` API does not support lambdas generated by `invokedynamic`.
- Calling `.toString()` on such a lambda produces a less readable string representation:

```
fun main() {
    println({})

    // With Kotlin 1.9.24 and reflection, returns
    // () → kotlin.Unit

    // With Kotlin 2.0.0, returns
    // FileKt$$Lambda$13/0x00007f88a0004608@506e1b77
}
```

To retain the legacy behavior of generating lambda functions, you can either:

- Annotate specific lambdas with `@JvmSerializableLambda`.
- Use the compiler option `-Xlambdas=class` to generate all lambdas in a module using the legacy method.

The kotlinx-metadata-jvm library is Stable

In Kotlin 2.0.0, the `kotlinx-metadata-jvm` library became Stable. Now that the library has changed to the `kotlin` package and coordinates, you can find it as `kotlin-metadata-jvm` (without the "x").

Previously, the `kotlinx-metadata-jvm` library had its own publishing scheme and version. Now, we will build and publish the `kotlin-metadata-jvm` updates as part of the Kotlin release cycle, with the same backward compatibility guarantees as the Kotlin standard library.

The `kotlin-metadata-jvm` library provides an API to read and modify metadata of binary files generated by the Kotlin/JVM compiler.

Kotlin/Native

This version brings the following changes:

- Monitoring GC performance with signposts
- Resolving conflicts with Objective-C methods
- Changed log level for compiler arguments in Kotlin/Native
- Explicitly added standard library and platform dependencies to Kotlin/Native
- Tasks error in Gradle configuration cache

Monitoring GC performance with signposts on Apple platforms

Previously, it was only possible to monitor the performance of Kotlin/Native's garbage collector (GC) by looking into logs. However, these logs were not integrated with Xcode Instruments, a popular toolkit for investigating issues with iOS apps' performance.

Since Kotlin 2.0.0, GC reports pauses with signposts that are available in Instruments. Signposts allow for custom logging within your app, so now, when debugging iOS app performance, you can check if a GC pause corresponds to the application freeze.

Learn more about GC performance analysis in the documentation.

Resolving conflicts with Objective-C methods

Objective-C methods can have different names, but the same number and types of parameters. For example, `locationManager:didEnterRegion:` and `locationManager:didExitRegion:`. In Kotlin, these methods have the same signature, so an attempt to use them triggers a conflicting overloads error.

Previously, you had to manually suppress conflicting overloads to avoid this compilation error. To improve Kotlin interoperability with Objective-C, the Kotlin 2.0.0 introduces the new `@ObjCSignatureOverride` annotation.

The annotation instructs the Kotlin compiler to ignore conflicting overloads, in case several functions with the same argument types but different argument names are inherited from the Objective-C class.

Applying this annotation is also safer than general error suppression. This annotation can only be used in the case of overriding Objective-C methods, which are supported and tested, while general suppression may hide important errors and lead to silently broken code.

Changed log level for compiler arguments

In this release, the log level for compiler arguments in Kotlin/Native Gradle tasks, such as `compile`, `link`, and `cinterop`, has changed from `info` to `debug`.

With `debug` as its default value, the log level is consistent with other Gradle compilation tasks and provides detailed debugging information, including all compiler arguments.

Explicitly added standard library and platform dependencies to Kotlin/Native

Previously, the Kotlin/Native compiler resolved standard library and platform dependencies implicitly, which caused inconsistencies in the way the Kotlin Gradle plugin worked across Kotlin targets.

Now, each Kotlin/Native Gradle compilation explicitly includes standard library and platform dependencies in its compile-time library path via the `compileDependencyFiles` compilation parameter.

Tasks error in Gradle configuration cache

Since Kotlin 2.0.0, you may encounter a configuration cache error with messages indicating: `invocation of Task.project at execution time is unsupported`.

This error appears in tasks such as `NativeDistributionCommonizerTask` and `KotlinNativeCompile`.

However, this is a false-positive error. The underlying issue is the presence of tasks that are not compatible with the Gradle configuration cache, like the `publish*` task.

This discrepancy may not be immediately apparent, as the error message suggests a different root cause.

As the precise cause isn't explicitly stated in the error report, the Gradle team is already addressing the issue to fix reports.

Kotlin/Wasm

Kotlin 2.0.0 improves performance and interoperability with JavaScript:

- Optimized production builds by default using Binaryen
- Support for named export
- Support for unsigned primitive types in functions with `@JsExport`
- Generation of TypeScript declaration files in Kotlin/Wasm
- Support for catching JavaScript exceptions
- New exception handling proposal is now supported as an option
- The `withWasm()` function is split into JS and WASI variants

Optimized production builds by default using Binaryen

The Kotlin/Wasm toolchain now applies the Binaryen tool during production compilation to all projects, as opposed to the previous manual setup approach. By our estimations, it should improve runtime performance and reduce the binary size for your project.

This change only affects production compilation. The development compilation process stays the same.

Support for named export

Previously, all exported declarations from Kotlin/Wasm were imported into JavaScript using default export:

```
//JavaScript:
import Module from "./index.mjs"

Module.add()
```

Now, you can import each Kotlin declaration marked with `@JsExport` by name:

```
// Kotlin:
@JsExport
fun add(a: Int, b: Int) = a + b
```

```
//JavaScript:
import { add } from "./index.mjs"
```

Named exports make it easier to share code between Kotlin and JavaScript modules. They improve readability and help you manage dependencies between modules.

Support for unsigned primitive types in functions with @JsExport

Starting from Kotlin 2.0.0, you can use unsigned primitive types inside external declarations and functions with the `@JsExport` annotation that makes Kotlin/Wasm functions available in JavaScript code.

This helps to mitigate the previous limitation that prevented the unsigned primitives from being used directly inside exported and external declarations. Now you can export functions with unsigned primitives as a return or parameter type and consume external declarations that return or consume unsigned primitives.

For more information on Kotlin/Wasm interoperability with JavaScript, see the documentation.

Generation of TypeScript declaration files in Kotlin/Wasm

> Generating TypeScript declaration files in Kotlin/Wasm is Experimental. It may be dropped or changed at any time.

In Kotlin 2.0.0, the Kotlin/Wasm compiler is now capable of generating TypeScript definitions from any `@JsExport` declarations in your Kotlin code. These definitions can be used by IDEs and JavaScript tools to provide code autocompletion, help with type checks, and make it easier to include Kotlin code in JavaScript.

The Kotlin/Wasm compiler collects any top-level functions marked with `@JsExport` and automatically generates TypeScript definitions in a `.d.ts` file.

To generate TypeScript definitions, in your `build.gradle(.kts)` file in the `wasmJs {}` block, add the `generateTypeScriptDefinitions()` function:

```
kotlin {
    wasmJs {
        binaries.executable()
        browser {
        }
        generateTypeScriptDefinitions()
    }
}
```

Support for catching JavaScript exceptions

Previously, Kotlin/Wasm code could not catch JavaScript exceptions, making it difficult to handle errors originating from the JavaScript side of the program.

In Kotlin 2.0.0, we have implemented support for catching JavaScript exceptions within Kotlin/Wasm. This implementation allows you to use `try-catch` blocks, with specific types like `Throwable` or `JsException`, to handle these errors properly.

Additionally, `finally` blocks, which help execute code regardless of exceptions, also work correctly. While we're introducing support for catching JavaScript exceptions, no additional information is provided when a JavaScript exception, like a call stack, occurs. However, we are working on these implementations.

New exception handling proposal is now supported as an option

In this release, we introduce support for the new version of WebAssembly's exception handling proposal within Kotlin/Wasm.

This update ensures the new proposal aligns with Kotlin requirements, enabling the use of Kotlin/Wasm on virtual machines that only support the latest version of the proposal.

Activate the new exception handling proposal by using the `-Xwasm-use-new-exception-proposal` compiler option, which is turned off by default.

The withWasm() function is split into JS and WASI variants

The `withWasm()` function, which used to provide Wasm targets for hierarchy templates, is deprecated in favor of specialized `withWasmJs()` and `withWasmWasi()` functions.

Now you can separate the WASI and JS targets between different groups in the tree definition.

Kotlin/JS

Among other changes, this version brings modern JS compilation to Kotlin, supporting more features from the ES2015 standard:

- New compilation target
- Suspend functions as ES2015 generators
- Passing arguments to the main function
- Per-file compilation for Kotlin/JS projects
- Improved collection interoperability
- Support for createInstance()

- Support for type-safe plain JavaScript objects
- Support for npm package manager
- Changes to compilation tasks
- Discontinuing legacy Kotlin/JS JAR artifacts

New compilation target

In Kotlin 2.0.0, we're adding a new compilation target to Kotlin/JS, `es2015`. This is a new way for you to enable all the ES2015 features supported in Kotlin at once.

You can set it up in your `build.gradle(.kts)` file like this:

```
kotlin {
    js {
        compilerOptions {
            target.set("es2015")
        }
    }
}
```

The new target automatically turns on ES classes and modules and the newly supported ES generators.

Suspend functions as ES2015 generators

This release introduces Experimental support for ES2015 generators for compiling suspend functions.

Using generators instead of state machines should improve the final bundle size of your project. For example, the JetBrains team managed to decrease the bundle size of its Space project by 20% by using the ES2015 generators.

Learn more about ES2015 (ECMAScript 2015, ES6) in the official documentation.

Passing arguments to the main function

Starting with Kotlin 2.0.0, you can specify a source of your `args` for the `main()` function. This feature makes it easier to work with the command line and pass the arguments.

To do this, define the `js {}` block with the new `passAsArgumentToMainFunction()` function, which returns an array of strings:

```
kotlin {
    js {
        binary.executable()
        passAsArgumentToMainFunction("Deno.args")
    }
}
```

The function is executed at runtime. It takes the JavaScript expression and uses it as the `args: Array<String>` argument instead of the `main()` function call.

Also, if you use the Node.js runtime, you can take advantage of a special alias. It allows you to pass `process.argv` to the `args` parameter once instead of adding it manually every time:

```
kotlin {
    js {
        binary.executable()
        nodejs {
            passProcessArgvToMainFunction()
        }
    }
}
```

Per-file compilation for Kotlin/JS projects

Kotlin 2.0.0 introduces a new granularity option for the Kotlin/JS project output. You can now set up a per-file compilation that generates one JavaScript file for each Kotlin file. It helps to significantly optimize the size of the final bundle and improve the loading time of the program.

Previously, there were only two output options. The Kotlin/JS compiler could generate a single `.js` file for the whole project. However, this file might be too large and inconvenient to use. Whenever you wanted to use a function from your project, you had to include the entire JavaScript file as a dependency. Alternatively, you could configure a compilation of a separate `.js` file for each project module. This is still the default option.

Since module files could also be too large, with Kotlin 2.0.0, we add a more granular output that generates one (or two, if the file contains exported declarations) JavaScript file per each Kotlin file. To enable the per-file compilation mode:

1. Add the `useEsModules()` function to your build file to support ECMAScript modules:

   ```
   // build.gradle.kts
   kotlin {
       js(IR) {
           useEsModules() // Enables ES2015 modules
           browser()
       }
   }
   ```

   You can also use the new `es2015` compilation target for that.

2. Apply the `-Xir-per-file` compiler option or update your `gradle.properties` file with:

   ```
   # gradle.properties
   kotlin.js.ir.output.granularity=per-file // `per-module` is the default
   ```

Improved collection interoperability

Starting with Kotlin 2.0.0, it's possible to export declarations with a Kotlin collection type inside the signature to JavaScript (and TypeScript). This applies to `Set`, `Map`, and `List` collection types and their mutable counterparts.

To use Kotlin collections in JavaScript, first mark the necessary declarations with `@JsExport` annotation:

```kotlin
// Kotlin
@JsExport
data class User(
    val name: String,
    val friends: List<User> = emptyList()
)

@JsExport
val me = User(
    name = "Me",
    friends = listOf(User(name = "Kodee"))
)
```

You can then consume them from JavaScript as regular JavaScript arrays:

```javascript
// JavaScript
import { User, me, KtList } from "my-module"

const allMyFriendNames = me.friends
    .asJsReadonlyArrayView()
    .map(x => x.name) // ['Kodee']
```

Unfortunately, creating Kotlin collections from JavaScript is still unavailable. We're planning to add this functionality in Kotlin 2.0.20.

Support for createInstance()

Starting with Kotlin 2.0.0, you can use the `createInstance()` function from the Kotlin/JS target. Previously, it was only available on the JVM.

This function from the KClass interface creates a new instance of the specified class, which is useful for getting the runtime reference to a Kotlin class.

Support for type-safe plain JavaScript objects

The `js-plain-objects` plugin is Experimental. It may be dropped or changed at any time. The `js-plain-objects` plugin **only** supports the K2 compiler.

To make it easier to work with JavaScript APIs, in Kotlin 2.0.0, we provide a new plugin: `js-plain-objects`, which you can use to create type-safe plain JavaScript objects. The plugin checks your code for any external interfaces that have a `@JsPlainObject` annotation and adds:

- An inline `invoke` operator function inside the companion object that you can use as a constructor.
- A `.copy()` function that you can use to create a copy of your object while adjusting some of its properties.

For example:

```
import kotlinx.js.JsPlainObject

@JsPlainObject
external interface User {
    var name: String
    val age: Int
    val email: String?
}

fun main() {
    // Creates a JavaScript object
    val user = User(name = "Name", age = 10)
    // Copies the object and adds an email
    val copy = user.copy(age = 11, email = "some@user.com")

    println(JSON.stringify(user))
    // { "name": "Name", "age": 10 }
    println(JSON.stringify(copy))
    // { "name": "Name", "age": 11, "email": "some@user.com" }
}
```

Any JavaScript objects created with this approach are safer because instead of only seeing errors at runtime, you can see them at compile time or even highlighted by your IDE.

Consider this example, which uses a `fetch()` function to interact with a JavaScript API using external interfaces to describe the shape of the JavaScript objects:

```
import kotlinx.js.JsPlainObject

@JsPlainObject
external interface FetchOptions {
    val body: String?
    val method: String
}

// A wrapper for Window.fetch
suspend fun fetch(url: String, options: FetchOptions? = null) = TODO("Add your custom behavior here")

// A compile-time error is triggered as "metod" is not recognized
// as method
fetch("https://google.com", options = FetchOptions(metod = "POST"))
// A compile-time error is triggered as method is required
fetch("https://google.com", options = FetchOptions(body = "SOME STRING"))
```

In comparison, if you use the `js()` function instead to create your JavaScript objects, errors are only found at runtime or aren't triggered at all:

```
suspend fun fetch(url: String, options: FetchOptions? = null) = TODO("Add your custom behavior here")

// No error is triggered. As "metod" is not recognized, the wrong method
// (GET) is used.
fetch("https://google.com", options = js("{ metod: 'POST' }"))

// By default, the GET method is used. A runtime error is triggered as
// body shouldn't be present.
fetch("https://google.com", options = js("{ body: 'SOME STRING' }"))
// TypeError: Window.fetch: HEAD or GET Request cannot have a body
```

To use the `js-plain-objects` plugin, add the following to your `build.gradle(.kts)` file:

Kotlin

```
plugins {
    kotlin("plugin.js-plain-objects") version "2.0.0"
}
```

Groovy

```
plugins {
    id "org.jetbrains.kotlin.plugin.js-plain-objects" version "2.0.0"
}
```

Support for npm package manager

Previously, it was only possible for the Kotlin Multiplatform Gradle plugin to use Yarn as a package manager to download and install npm dependencies. From Kotlin 2.0.0, you can use npm as your package manager instead. Using npm as a package manager means that you have one less tool to manage during your setup.

For backward compatibility, Yarn is still the default package manager. To use npm as your package manager, set the following property in your `gradle.properties` file:

```
kotlin.js.yarn = false
```

Changes to compilation tasks

Previously, the `webpack` and `distributeResources` compilation tasks both targeted the same directories. Moreover, the `distribution` task declared the `dist` as its output directory as well. This resulted in overlapping outputs and produced a compilation warning.

So, starting with Kotlin 2.0.0, we've implemented the following changes:

- The `webpack` task now targets a separate folder.
- The `distributeResources` task has been completely removed.
- The `distribution` task now has the `Copy` type and targets the `dist` folder.

Discontinuing legacy Kotlin/JS JAR artifacts

Starting with Kotlin 2.0.0, the Kotlin distribution no longer contains legacy Kotlin/JS artifacts with the `.jar` extension. Legacy artifacts were used in the unsupported old Kotlin/JS compiler and unnecessary for the IR compiler, which uses the `klib` format.

Gradle improvements

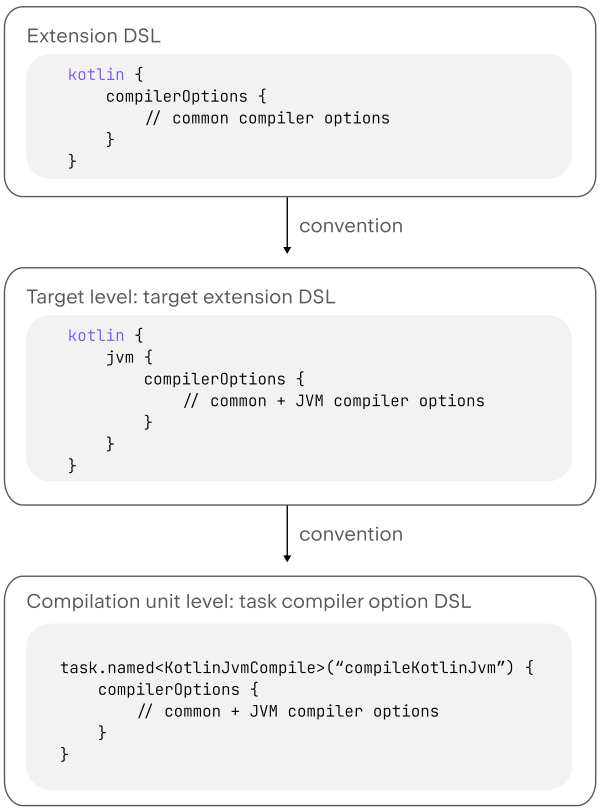
Kotlin 2.0.0 is fully compatible with Gradle 6.8.3 through 8.5. You can also use Gradle versions up to the latest Gradle release, but if you do, keep in mind that you might encounter deprecation warnings or some new Gradle features might not work.

This version brings the following changes:

- New Gradle DSL for compiler options in multiplatform projects

- New Compose compiler Gradle plugin
- New attribute to distinguish JVM and Android published libraries
- Improved Gradle dependency handling for CInteropProcess in Kotlin/Native
- Visibility changes in Gradle
- New directory for Kotlin data in Gradle projects
- Kotlin/Native compiler downloaded when needed
- Deprecating old ways of defining compiler options
- Bumped minimum AGP supported version
- New Gradle property for trying the latest language version
- New JSON output format for build reports
- kapt configurations inherit annotation processors from superconfigurations
- Kotlin Gradle plugin no longer uses deprecated Gradle conventions

New Gradle DSL for compiler options in multiplatform projects



> This feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Prior to Kotlin 2.0.0, configuring compiler options in a multiplatform project with Gradle was only possible at a low level, such as per task, compilation, or source set. To make it easier to configure compiler options more generally in your projects, Kotlin 2.0.0 comes with a new Gradle DSL.

With this new DSL, you can configure compiler options at the extension level for all the targets and shared source sets like `commonMain` and at a target level for a specific target:

```
kotlin {
    compilerOptions {
        // Extension-level common compiler options that are used as defaults
        // for all targets and shared source sets
        allWarningsAsErrors.set(true)
    }
    jvm {
        compilerOptions {
            // Target-level JVM compiler options that are used as defaults
            // for all compilations in this target
            noJdk.set(true)
        }
    }
}
```

The overall project configuration now has three layers. The highest is the extension level, then the target level and the lowest is the compilation unit (which is usually a compilation task):

Kotlin compiler options levels

The settings at a higher level are used as a convention (default) for a lower level:

- The values of extension compiler options are the default for target compiler options, including shared source sets, like `commonMain`, `nativeMain`, and `commonTest`.
- The values of target compiler options are used as the default for compilation unit (task) compiler options, for example, `compileKotlinJvm` and `compileTestKotlinJvm` tasks.

In turn, configurations made at a lower level override related settings at a higher level:

- Task-level compiler options override related configurations at the target or the extension level.
- Target-level compiler options override related configurations at the extension level.

When configuring your project, keep in mind that some old ways of setting up compiler options have been deprecated.

We encourage you to try the new DSL out in your multiplatform projects and leave feedback in YouTrack, as we plan to make this DSL the recommended approach for configuring compiler options.

New Compose compiler Gradle plugin

The Jetpack Compose compiler, which translates composables into Kotlin code, has now been merged into the Kotlin repository. This will help transition Compose projects to Kotlin 2.0.0, as the Compose compiler will always ship simultaneously with Kotlin. This also bumps the Compose compiler version to 2.0.0.

To use the new Compose compiler in your projects, apply the `org.jetbrains.kotlin.plugin.compose` Gradle plugin in your `build.gradle(.kts)` file and set its version equal to Kotlin 2.0.0.

To learn more about this change and see the migration instructions, see the Compose compiler documentation.

New attribute to distinguish JVM and Android-published libraries

Starting with Kotlin 2.0.0, the `org.gradle.jvm.environment` Gradle attribute is published by default with all Kotlin variants.

The attribute helps distinguish JVM and Android variants of Kotlin Multiplatform libraries. It indicates that a certain library variant is better suited for a certain JVM environment. The target environment could be "android", "standard-jvm", or "no-jvm".

Publishing this attribute should make consuming Kotlin Multiplatform libraries with JVM and Android targets more robust from non-multiplatform clients as well, such as Java-only projects.

If necessary, you can disable attribute publication. To do that, add the following Gradle option to your `gradle.properties` file:

```
kotlin.publishJvmEnvironmentAttribute=false
```

Improved Gradle dependency handling for CInteropProcess in Kotlin/Native

In this release, we enhanced the handling of the `defFile` property to ensure better Gradle task dependency management in Kotlin/Native projects.

Before this update, Gradle builds could fail if the `defFile` property was designated as an output of another task that hadn't been executed yet. The workaround for this issue was to add a dependency on this task:

```
kotlin {
    macosArm64("native") {
        compilations.getByName("main") {
            cinterops {
                val cinterop by creating {
                    defFileProperty.set(createDefFileTask.flatMap { it.defFile.asFile })
                    project.tasks.named(interopProcessingTaskName).configure {
                        dependsOn(createDefFileTask)
                    }
                }
            }
        }
    }
}
```

To fix this, there is a new `RegularFileProperty` property called `definitionFile`. Now, Gradle lazily verifies the presence of the `definitionFile` property after the connected task has run later in the build process. This new approach eliminates the need for additional dependencies.

The `CInteropProcess` task and the `CInteropSettings` class use the `definitionFile` property instead of `defFile` and `defFileProperty`:

Kotlin

```
kotlin {
    macosArm64("native") {
        compilations.getByName("main") {
            cinterops {
                val cinterop by creating {
                    definitionFile.set(project.file("def-file.def"))
                }
            }
        }
    }
}
```

Groovy

```
kotlin {
    macosArm64("native") {
        compilations.main {
            cinterops {
                cinterop {
                    definitionFile.set(project.file("def-file.def"))
                }
            }
        }
    }
}
```

`defFile` and `defFileProperty` parameters are deprecated.

Visibility changes in Gradle

This change impacts only Kotlin DSL users.

In Kotlin 2.0.0, we've modified the Kotlin Gradle Plugin for better control and safety in your build scripts. Previously, certain Kotlin DSL functions and properties intended for a specific DSL context would inadvertently leak into other DSL contexts. This leakage could lead to the use of incorrect compiler options, settings being applied multiple times, and other misconfigurations:

```
kotlin {
    // Target DSL couldn't access methods and properties defined in the
    // kotlin{} extension DSL
    jvm {
        // Compilation DSL couldn't access methods and properties defined
        // in the kotlin{} extension DSL and Kotlin jvm{} target DSL
        compilations.configureEach {
            // Compilation task DSLs couldn't access methods and
            // properties defined in the kotlin{} extension, Kotlin jvm{}
            // target or Kotlin compilation DSL
            compileTaskProvider.configure {
                // For example:
                explicitApi()
                // ERROR as it is defined in the kotlin{} extension DSL
                mavenPublication {}
                // ERROR as it is defined in the Kotlin jvm{} target DSL
                defaultSourceSet {}
                // ERROR as it is defined in the Kotlin compilation DSL
            }
        }
    }
}
```

To fix this issue, we've added the `@KotlinGradlePluginDsl` annotation, preventing the exposure of the Kotlin Gradle plugin DSL functions and properties to levels where they are not intended to be available. The following levels are separated from each other:

- Kotlin extension
- Kotlin target
- Kotlin compilation
- Kotlin compilation task

For the most popular cases, we've added compiler warnings with suggestions on how to fix them if your build script is configured incorrectly. For example:

```
kotlin {
    jvm {
        sourceSets.getByName("jvmMain").dependencies {
            implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core-jvm:1.7.3")
        }
    }
}
```

In this case, the warning message for `sourceSets` is:

```
[DEPRECATION] 'sourceSets: NamedDomainObjectContainer<KotlinSourceSet>' is deprecated.Accessing
'sourceSets' container on the Kotlin target level DSL is deprecated. Consider configuring 'sourceSets'
on the Kotlin extension level.
```

We would appreciate your feedback on this change! Share your comments directly to Kotlin developers in our #gradle Slack channel. Get a Slack invite.

New directory for Kotlin data in Gradle projects

> Do not commit the `.kotlin` directory to version control. For example, if you are using Git, add `.kotlin` to your project's `.gitignore` file.

In Kotlin 1.8.20, the Kotlin Gradle plugin switched to storing its data in the Gradle project cache directory: `<project-root-directory>/.gradle/kotlin`. However, the `.gradle` directory is reserved for Gradle only, and as a result it's not future-proof.

To solve this, as of Kotlin 2.0.0, we will store Kotlin data in your `<project-root-directory>/.kotlin` by default. We will continue to store some data in the `.gradle/kotlin` directory for backward compatibility.

The new Gradle properties you can configure are:

Gradle property	Description
`kotlin.project.persistent.dir`	Configures the location where your project-level data is stored. Default: `<project-root-directory>/.kotlin`
`kotlin.project.persistent.dir.gradle.disableWrite`	A boolean value that controls whether writing Kotlin data to the `.gradle` directory is disabled. Default: `false`

Add these properties to the `gradle.properties` file in your projects for them to take effect.

Kotlin/Native compiler downloaded when needed

Before Kotlin 2.0.0, if you had a Kotlin/Native target configured in the Gradle build script of your multiplatform project, Gradle would always download the Kotlin/Native compiler in the configuration phase.

This happened even if there was no task to compile code for a Kotlin/Native target that was due to run in the execution phase. Downloading the Kotlin/Native compiler in this way was particularly inefficient for users who only wanted to check the JVM or JavaScript code in their projects. For example, to perform tests or checks with their Kotlin project as part of a CI process.

In Kotlin 2.0.0, we changed this behavior in the Kotlin Gradle plugin so that the Kotlin/Native compiler is downloaded in the execution phase and **only** when a compilation is requested for a Kotlin/Native target.

In turn, the Kotlin/Native compiler's dependencies are now downloaded not as a part of the compiler, but in the execution phase as well.

If you encounter any issues with the new behavior, you can temporarily switch back to the previous behavior by adding the following Gradle property to your `gradle.properties` file:

```
kotlin.native.toolchain.enabled=false
```

Starting with Kotlin 1.9.20-Beta, the Kotlin/Native distribution is published to Maven Central along with the CDN.

This allowed us to change how Kotlin looks for and downloads the necessary artifacts. Instead of the CDN, by default, it now uses the Maven repositories that you specified in the `repositories {}` block of your project.

You can temporarily switch this behavior back by setting the following Gradle property in your `gradle.properties` file:

```
kotlin.native.distribution.downloadFromMaven=false
```

Please report any problems to our issue tracker YouTrack. Both of these Gradle properties that change the default behavior are temporary and will be removed in future releases.

Deprecated old ways of defining compiler options

In this release, we continue to refine how you can set up compiler options. It should resolve ambiguity between different ways and make the project configuration more straightforward.

Since Kotlin 2.0.0, the following DSLs for specifying compiler options are deprecated:

- The `kotlinOptions` DSL from the `KotlinCompile` interface that implements all Kotlin compilation tasks. Use `KotlinCompilationTask<CompilerOptions>` instead.
- The `compilerOptions` property with the `HasCompilerOptions` type from the `KotlinCompilation` interface. This DSL was inconsistent with other DSLs and configured the same `KotlinCommonCompilerOptions` object as `compilerOptions` inside the `KotlinCompilation.compileTaskProvider` compilation task, which was confusing.

  Instead, we recommend using the `compilerOptions` property from the Kotlin compilation task:

  ```
  kotlinCompilation.compileTaskProvider.configure {
      compilerOptions { ... }
  }
  ```

  For example:

  ```
  kotlin {
      js(IR) {
          compilations.all {
              compileTaskProvider.configure {
                  compilerOptions.freeCompilerArgs.add("-Xir-minimized-member-names=false")
              }
          }
      }
  }
  ```

- The `kotlinOptions` DSL from the `KotlinCompilation` interface.
- The `kotlinOptions` DSL from the `KotlinNativeArtifactConfig` interface, the `KotlinNativeLink` class, and the `KotlinNativeLinkArtifactTask` class. Use the `toolOptions` DSL instead.
- The `dceOptions` DSL from the `KotlinJsDce` interface. Use the `toolOptions` DSL instead.

For more information on how to specify compiler options in the Kotlin Gradle plugin, see How to define options.

Bumped minimum supported AGP version

Starting with Kotlin 2.0.0, the minimum supported Android Gradle plugin version is 7.1.3.

New Gradle property for trying the latest language version

Prior to Kotlin 2.0.0, we had the following Gradle property to try out the new K2 compiler: `kotlin.experimental.tryK2`. Now that the K2 compiler is enabled by default in Kotlin 2.0.0, we decided to evolve this property into a new form that you can use to try the latest language version in your projects:

`kotlin.experimental.tryNext`. When you use this property in your `gradle.properties` file, the Kotlin Gradle plugin increments the language version to one above the default value for your Kotlin version. For example, in Kotlin 2.0.0, the default language version is 2.0, so the property configures language version 2.1.

This new Gradle property produces similar metrics in build reports as before with `kotlin.experimental.tryK2`. The language version configured is included in the output. For example:

```
##### 'kotlin.experimental.tryNext' results #####
:app:compileKotlin: 2.1 language version
:lib:compileKotlin: 2.1 language version
##### 100% (2/2) tasks have been compiled with Kotlin 2.1 #####
```

To learn more about how to enable build reports and their content, see Build reports.

New JSON output format for build reports

In Kotlin 1.7.0, we introduced build reports to help track compiler performance. Over time, we've added more metrics to make these reports even more detailed and helpful when investigating performance issues. Previously, the only output format for a local file was the `*.txt` format. In Kotlin 2.0.0, we support the JSON output format to make it even easier to analyze using other tools.

To configure JSON output format for your build reports, declare the following properties in your `gradle.properties` file:

```
kotlin.build.report.output=json

// The directory to store your build reports
kotlin.build.report.json.directory=my/directory/path
```

Alternatively, you can run the following command:

```
./gradlew assemble -Pkotlin.build.report.output=json -
Pkotlin.build.report.json.directory="my/directory/path"
```

Once configured, Gradle generates your build reports in the directory that you specify with the name: `${project_name}-date-time-<sequence_number>.json`.

Here's an example snippet from a build report with JSON output format that contains build metrics and aggregated metrics:

```
"buildOperationRecord": [
    {
     "path": ":lib:compileKotlin",
      "classFqName": "org.jetbrains.kotlin.gradle.tasks.KotlinCompile_Decorated",
      "startTimeMs": 1714730820601,
      "totalTimeMs": 2724,
      "buildMetrics": {
        "buildTimes": {
          "buildTimesNs": {
            "CLEAR_OUTPUT": 713417,
            "SHRINK_AND_SAVE_CURRENT_CLASSPATH_SNAPSHOT_AFTER_COMPILATION": 19699333,
            "IR_TRANSLATION": 281000000,
            "NON_INCREMENTAL_LOAD_CURRENT_CLASSPATH_SNAPSHOT": 14088042,
            "CALCULATE_OUTPUT_SIZE": 1301500,
            "GRADLE_TASK": 2724000000,
            "COMPILER_INITIALIZATION": 263000000,
            "IR_GENERATION": 74000000,
...
          }
        }
...
 "aggregatedMetrics": {
    "buildTimes": {
      "buildTimesNs": {
        "CLEAR_OUTPUT": 782667,
        "SHRINK_AND_SAVE_CURRENT_CLASSPATH_SNAPSHOT_AFTER_COMPILATION": 22031833,
        "IR_TRANSLATION": 333000000,
        "NON_INCREMENTAL_LOAD_CURRENT_CLASSPATH_SNAPSHOT": 14890292,
        "CALCULATE_OUTPUT_SIZE": 2370750,
        "GRADLE_TASK": 3234000000,
        "COMPILER_INITIALIZATION": 292000000,
        "IR_GENERATION": 89000000,
...
      }
    }
```

kapt configurations inherit annotation processors from superconfigurations

Prior to Kotlin 2.0.0, if you wanted to define a common set of annotation processors in a separate Gradle configuration and extend this configuration in kapt-specific configurations for your subprojects, kapt would skip annotation processing because it couldn't find any annotation processors. In Kotlin 2.0.0, kapt can successfully detect that there are indirect dependencies on your annotation processors.

As an example, for a subproject using Dagger, in your `build.gradle(.kts)` file, use the following configuration:

```
val commonAnnotationProcessors by configurations.creating
configurations.named("kapt") { extendsFrom(commonAnnotationProcessors) }

dependencies {
    implementation("com.google.dagger:dagger:2.48.1")
    commonAnnotationProcessors("com.google.dagger:dagger-compiler:2.48.1")
}
```

In this example, the `commonAnnotationProcessors` Gradle configuration is your common configuration for annotation processing that you want to be used for all your projects. You use the `extendsFrom()` method to add `commonAnnotationProcessors` as a superconfiguration. kapt sees that the `commonAnnotationProcessors` Gradle configuration has a dependency on the Dagger annotation processor. Therefore, kapt includes the Dagger annotation processor in its configuration for annotation processing.

Thanks to Christoph Loy for the implementation!

Kotlin Gradle plugin no longer uses deprecated Gradle conventions

Prior to Kotlin 2.0.0, if you used Gradle 8.2 or higher, the Kotlin Gradle plugin incorrectly used Gradle conventions that had been deprecated in Gradle 8.2. This led to Gradle reporting build deprecations. In Kotlin 2.0.0, the Kotlin Gradle plugin has been updated to no longer trigger these deprecation warnings when you use Gradle 8.2 or higher.

Standard library

This release brings further stability to the Kotlin standard library and makes even more existing functions common for all platforms:

- Stable replacement of the enum class values generic function
- Stable AutoCloseable interface
- Common protected property AbstractMutableList.modCount
- Common protected function AbstractMutableList.removeRange
- Common String.toCharArray(destination)

Stable replacement of the enum class values generic function

In Kotlin 2.0.0, the `enumEntries<T>()` function becomes Stable. The `enumEntries<T>()` function is a replacement for the generic `enumValues<T>()` function. The new function returns a list of all enum entries for the given enum type `T`. The `entries` property for enum classes was previously introduced and also stabilized to replace the synthetic `values()` function. For more information about the entries property, see What's new in Kotlin 1.8.20.

> The `enumValues<T>()` function is still supported, but we recommend that you use the `enumEntries<T>()` function instead because it has less of a performance impact. Every time you call `enumValues<T>()`, a new array is created, whereas whenever you call `enumEntries<T>()`, the same list is returned each time, which is far more efficient.

For example:

```
enum class RGB { RED, GREEN, BLUE }

inline fun <reified T : Enum<T>> printAllValues() {
    print(enumEntries<T>().joinToString { it.name })
}

printAllValues<RGB>()
// RED, GREEN, BLUE
```

Stable AutoCloseable interface

In Kotlin 2.0.0, the common `AutoCloseable` interface becomes Stable. It allows you to easily close resources and includes a couple of useful functions:

- The `use()` extension function, which executes a given block function on the selected resource and then closes it down correctly, whether an exception is thrown or not.
- The `AutoCloseable()` constructor function, which creates instances of the `AutoCloseable` interface.

In the example below, we define the `XMLWriter` interface and assume that there is a resource that implements it. For example, this resource could be a class that opens a file, writes XML content, and then closes it:

```
interface XMLWriter {
    fun document(encoding: String, version: String, content: XMLWriter.() -> Unit)
    fun element(name: String, content: XMLWriter.() -> Unit)
    fun attribute(name: String, value: String)
    fun text(value: String)

    fun flushAndClose()
}

fun writeBooksTo(writer: XMLWriter) {
    val autoCloseable = AutoCloseable { writer.flushAndClose() }
    autoCloseable.use {
        writer.document(encoding = "UTF-8", version = "1.0") {
            element("bookstore") {
                element("book") {
                    attribute("category", "fiction")
                    element("title") { text("Harry Potter and the Prisoner of Azkaban") }
                    element("author") { text("J. K. Rowling") }
                    element("year") { text("1999") }
                    element("price") { text("29.99") }
                }
                element("book") {
                    attribute("category", "programming")
                    element("title") { text("Kotlin in Action") }
                    element("author") { text("Dmitry Jemerov") }
                    element("author") { text("Svetlana Isakova") }
                    element("year") { text("2017") }
                    element("price") { text("25.19") }
                }
            }
        }
    }
}
```

Common protected property AbstractMutableList.modCount

In this release, the `modCount` `protected` property of the `AbstractMutableList` interface becomes common. Previously, the `modCount` property was available on each platform but not for the common target. Now, you can create custom implementations of `AbstractMutableList` and access the property in common code.

The property keeps track of the number of structural modifications made to the collection. This includes operations that change the collection size or alter the list in a way that may cause iterations in progress to return incorrect results.

You can use the `modCount` property to register and detect concurrent modifications when implementing a custom list.

Common protected function AbstractMutableList.removeRange

In this release, the `removeRange()` `protected` function of the `AbstractMutableList` interface becomes common. Previously, it was available on each platform but not for the common target. Now, you can create custom implementations of `AbstractMutableList` and override the function in common code.

The function removes elements from this list following the specified range. By overriding this function, you can take advantage of the custom implementations and improve the performance of the list operation.

Common String.toCharArray(destination) function

This release introduces a common `String.toCharArray(destination)` function. Previously, it was only available on the JVM.

Let's compare it with the existing `String.toCharArray()` function. It creates a new `CharArray` that contains characters from the specified string. The new common `String.toCharArray(destination)` function, however, moves `String` characters into an existing destination `CharArray`. This is useful if you already have a buffer that you want to fill:

```
fun main() {
    val myString = "Kotlin is awesome!"
    val destinationArray = CharArray(myString.length)

    // Convert the string and store it in the destinationArray:
    myString.toCharArray(destinationArray)

    for (char in destinationArray) {
        print("$char ")
        // K o t l i n  i s  a w e s o m e !
    }
}
```

Install Kotlin 2.0.0

Starting from IntelliJ IDEA 2023.3 and Android Studio Iguana (2023.2.1) Canary 15, the Kotlin plugin is distributed as a bundled plugin included in your IDE. This means that you can't install the plugin from JetBrains Marketplace anymore.

To update to the new Kotlin version, change the Kotlin version to 2.0.0 in your build scripts.

Compatibility guide for Kotlin 2.0.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like updated changelogs or compiler warnings, this document provides a complete reference for migration from Kotlin 1.9 to Kotlin 2.0.

> The Kotlin K2 compiler is introduced as part of Kotlin 2.0. For information on the benefits of the new compiler, changes you might encounter during migration, and how to roll back to the previous compiler, see K2 compiler migration guide.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Deprecate use of a synthetic setter on a projected receiver

Issue: KT-54309

Component: Core language

Incompatible change type: source

Short summary: If you use the synthetic setter of a Java class to assign a type that conflicts with the class's projected type, an error is triggered.

Deprecation cycle:

- 1.8.20: report a warning when a synthetic property setter has a projected parameter type in contravariant position making call-site argument types incompatible
- 2.0.0: raise the warning to an error

Correct mangling when calling functions with inline class parameters that are overloaded in a Java subclass

Issue: KT-56545

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 2.0.0: use the correct mangling behavior in function invocations; to revert to the previous behaviour, use the `-XXLanguage:-MangleCallsToJavaMethodsWithValueClasses` compiler option.

Correct type approximation algorithm for contravariant captured types

Issue: KT-49404

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.20: report a warning on problematic calls
- 2.0.0: raise the warning to an error

Prohibit accessing property value before property initialization

Issue: KT-56408

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report an error when a property is accessed before initialization in the affected contexts

Report error when there's ambiguity in imported classes with the same name

Issue: KT-57750

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report an error when resolving a class name that is present in several packages imported with a star import

Generate Kotlin lambdas via invokedynamic and LambdaMetafactory by default

Issue: KT-45375

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 2.0.0: implement new behavior; lambdas are generated using `invokedynamic` and `LambdaMetafactory` by default

Forbid if condition with one branch when an expression is required

Issue: KT-57871

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report an error in case the `if` condition has only one branch

Prohibit violation of self upper bounds by passing a star-projection of a generic type

Issue: KT-61718

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report an error when self upper bounds are violated by passing a star-projection of a generic type

Approximate anonymous types in private inline functions return type

Issue: KT-54862

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.9.0: report a warning on private inline functions if the inferred return type contains an anonymous type
- 2.0.0: approximate return type of such private inline functions to a supertype

Change overload resolution behavior to prioritize local extension function calls over invoke conventions of local functional type properties

Issue: KT-37592

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 2.0.0: new overload resolution behavior; function calls are consistently prioritized over invoke conventions

Report error when an inherited member conflict occurs due to a change in a supertype from binary dependency

Issue: KT-51194

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.7.0: report a warning CONFLICTING_INHERITED_MEMBERS_WARNING on declarations where inherited member conflict has occurred in the supertype from binary dependency
- 2.0.0: raise the warning to an error: CONFLICTING_INHERITED_MEMBERS

Ignore @UnsafeVariance annotations on parameters in invariant types

Issue: KT-57609

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; the `@UnsafeVariance` annotation is ignored when reporting errors about type mismatch in contravariant parameters

Change type for out-of-call references to a companion object's member

Issue: KT-54316

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.20: report a warning on a companion object function reference type inferred as an unbound reference
- 2.0.0: change the behavior so that companion object function references are inferred as bound references in all usage contexts

Prohibit exposure of anonymous types from private inline functions

Issue: KT-33917

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.3.0: report a warning on calls to own members of anonymous objects, returned from private inline functions
- 2.0.0: approximate return type of such private inline functions to a supertype and don't resolve calls to anonymous object members

Report error for an unsound smart cast after a while-loop break

Issue: KT-22379

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; the old behavior can be restored by switching to language version 1.9

Report error when a variable of an intersection type is assigned a value that is not a subtype of that intersection type

Issue: KT-53752

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report an error when a variable having an intersection type is assigned a value that is not a subtype of that intersection type

Require opt-in when an interface constructed with a SAM constructor contains a method that requires an opt-in

Issue: KT-52628

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.7.20: report a warning for `OptIn` usages via SAM constructor
- 2.0.0: raise the warning to an error for `OptIn` usages via SAM constructor (or keep reporting the warning if `OptIn` marker severity is a warning)

Prohibit upper bound violation in typealias constructors

Issue: KT-54066

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.0: introduce a warning for cases when the upper bound is violated in typealias constructors
- 2.0.0: raise the warning to an error in the K2 compiler

Make the real type of a destructuring variable consistent with the explicit type when specified

Issue: KT-57011

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; the real type of destructuring variable is now consistent with the explicit type when specified

Require opt-in when calling a constructor that has parameter types with default values that require an opt-in

Issue: KT-55111

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.20: report a warning on constructor calls that has parameter types which require opt-in
- 2.0.0: raise the warning to an error (or keep reporting a warning if the `OptIn` marker severity is a warning)

Report ambiguity between a property and an enum entry with the same name at the same scope level

Issue: KT-52802

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.7.20: report a warning when the compiler resolves to a property instead of an enum entry at the same scope level
- 2.0.0: report ambiguity when the compiler encounters both a property and an enum entry with the same name at the same scope level in the K2 compiler (leaving the warning as is in the old compiler)

Change qualifier resolution behavior to prefer companion property over enum entry

Issue: KT-47310

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new resolution behavior; companion property is preferred over enum entry

Resolve invoke call receiver type and the invoke function type as if written in desugared form

Issue: KT-58260

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: resolve invoke call receiver type and the invoke function type independently as if they were written in a desugared form

Prohibit exposing private class members through non-private inline functions

Issue: KT-55179

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.9.0: report the `PRIVATE_CLASS_MEMBER_FROM_INLINE_WARNING` warning when calling private class companion object member from internal inline functions
- 2.0.0: raise this warning to the `PRIVATE_CLASS_MEMBER_FROM_INLINE` error

Correct nullability of definitely non-null types in projected generic types

Issue: KT-54663

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; projected types take into account all in-place not-null types

Change inferred type of prefix increment to match getter's return type instead of inc() operator's return type

Issue: KT-57178

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; inferred type of prefix increment is changed to match getter's return type instead of the `inc()` operator's return type

Enforce bound checks when inheriting inner classes from generic inner classes declared in superclasses

Issue: KT-61749

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report an error when upper bound of the type parameter of a generic inner superclass is violated

Forbid assigning callable references with SAM types when the expected type is a function type with a function type parameter

Issue: KT-64342

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report a compilation error on callable references with SAM types when the expected type is a function type with a function type parameter

Consider companion object scope for annotation resolution on companion objects

Issue: KT-64299

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 2.0.0: implement new behavior; the companion object scope is now not ignored during annotation resolution on companion objects

Change evaluation semantics for combination of safe calls and convention operators

Issue: KT-41034

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 1.4.0: report warnings on each incorrect call
- 2.0.0: implement new resolution behavior

Require properties with backing field and a custom setter to be immediately initialized

Issue: KT-58589

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 1.9.20: introduce the `MUST_BE_INITIALIZED` warning for cases where there is no primary constructor
- 2.0.0: raise the warning to an error

Prohibit Unit conversion on arbitrary expressions in invoke operator convention call

Issue: KT-61182

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 2.0.0: report an error when Unit conversion is applied to an arbitrary expression on variable and invoke resolution; use the `-XXLanguage:+UnitConversionsOnArbitraryExpressions` compiler option to keep the previous behavior with affected expressions.

Forbid nullable assignment to non-null Java field when the field is accessed with a safe call

Issue: KT-62998

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: report to an error in case a nullable is assigned to a non-null Java field

Require star-projected type when overriding a Java method containing a raw-type parameter

Issue: KT-57600

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; overriding is forbidden for raw type parameters

Change (V)::foo reference resolution when V has a companion

Issue: KT-47313

Component: Core language

Incompatible change type: behavioral

Deprecation cycle:

- 1.6.0: report a warning on callable references currently bound to companion object instances
- 2.0.0: implement new behavior; adding parentheses around a type no longer makes it a reference to the type's companion object instance

Forbid implicit non-public API access in effectively public inline functions

Issue: KT-54997

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.20: report a compilation warning when implicit non-public API is accessed in public inline functions
- 2.0.0: raise the warning to an error

Prohibit use-site get annotations on property getters

Issue: KT-57422

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.9.0: report a warning (an error in the progressive mode) on use-site `get` annotations on getters
- 2.0.0: raise the warning to the `INAPPLICABLE_TARGET_ON_PROPERTY` error; use `-XXLanguage:-ProhibitUseSiteGetTargetAnnotations` to revert to a warning

Prevent implicit inference of type parameters into upper bounds in builder inference lambda functions

Issue: KT-47986

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.7.20: report a warning (or an error in the progressive mode) when the type parameter for a type argument cannot be inferred into declared upper bounds
- 2.0.0: raise the warning to an error

Keep nullability when approximating local types in public signatures

Issue: KT-53982

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.0: flexible types are approximated by flexible supertypes; report a warning when a declaration is inferred to have a non-nullable type that should be nullable, prompting to specify the type explicitly to avoid NPEs
- 2.0.0: nullable types are approximated by nullable supertypes

Remove special handling for false && ... and false || ... for the purposes of smart-casting

Issue: KT-65776

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 2.0.0: implement new behavior; no special handling for `false && ...` and `false || ...`

Forbid inline open functions in enums

Issue: KT-34372

Component: Core language

Incompatible change type: source

Deprecation cycle:

- 1.8.0: report a warning on inline open functions in enums
- 2.0.0: raise the warning to an error

Tools

Visibility changes in Gradle

Issue: KT-64653

Component: Gradle

Incompatible change type: source

Short summary: Previously, certain Kotlin DSL functions and properties intended for a specific DSL context would inadvertently leak into other DSL contexts. We've added the `@KotlinGradlePluginDsl` annotation, which prevents the exposure of the Kotlin Gradle plugin DSL functions and properties to levels where they are not intended to be available. The following levels are separated from each other:

- Kotlin extension
- Kotlin target
- Kotlin compilation
- Kotlin compilation task

Deprecation cycle:

- 2.0.0: for most popular cases, the compiler reports warnings with suggestions on how to fix them if your build script is configured incorrectly; otherwise, the compiler reports an error

Deprecate kotlinOptions DSL

Issue: KT-63419

Component: Gradle

Incompatible change type: source

Short summary: The ability to configure compiler options through the `kotlinOptions` DSL and the related `KotlinCompile<KotlinOptions>` task interface have been deprecated.

Deprecation cycle:

- 2.0.0: report a warning

Deprecate compilerOptions in KotlinCompilation DSL

Issue: KT-65568

Component: Gradle

Incompatible change type: source

Short summary: The ability to configure the `compilerOptions` property in the `KotlinCompilation` DSL has been deprecated.

Deprecation cycle:

- 2.0.0: report a warning

Deprecate old ways of CInteropProcess handling

Issue: KT-62795

Component: Gradle

Incompatible change type: source

Short summary: the `CInteropProcess` task and the `CInteropSettings` class now use the `definitionFile` property instead of `defFile` and `defFileProperty`.

This eliminates the need to add extra `dependsOn` relations between the `CInteropProcess` task and the task that generates `defFile` when the `defFile` is dynamically generated.

In Kotlin/Native projects, Gradle now lazily verifies the presence of the `definitionFile` property after the connected task has run later in the build process.

Deprecation cycle:

- 2.0.0: `defFile` and `defFileProperty` parameters are deprecated
- 2.4.0: report an error for the deprecated `defFile` property

Remove kotlin.useK2 Gradle property

Issue: KT-64379

Component: Gradle

Incompatible change type: behavioral

Short summary: The `kotlin.useK2` Gradle property has been removed. In Kotlin 1.9.*, it could be used to enable the K2 compiler. In Kotlin 2.0.0 and later, the K2 compiler is enabled by default, so the property has no effect and cannot be used to switch back to the previous compiler.

Deprecation cycle:

- 1.8.20: the `kotlin.useK2` Gradle property is deprecated
- 2.0.0: the `kotlin.useK2` Gradle property is removed

Remove deprecated platform plugin IDs

Issue: KT-65187

Component: Gradle

Incompatible change type: source

Short summary: support for these platform plugin IDs have been removed:

- `kotlin-platform-android`
- `kotlin-platform-jvm`
- `kotlin-platform-js`
- `org.jetbrains.kotlin.platform.android`
- `org.jetbrains.kotlin.platform.jvm`
- `org.jetbrains.kotlin.platform.js`

Deprecation cycle:

- 1.3: the platform plugin IDs are deprecated
- 2.0.0: the platform plugin IDs are no longer supported

Remove outputFile JavaScript compiler option

Issue: KT-61116

Component: Gradle

Incompatible change type: source

Short summary: The `outputFile` JavaScript compiler option has been removed. Instead, you can use the `destinationDirectory` property of the `Kotlin2JsCompile` task to specify the directory where the compiled JavaScript output files are written.

Deprecation cycle:

- 1.9.25: the `outputFile` compiler option is deprecated
- 2.0.0: the `outputFile` compiler option is removed

What's new in Kotlin 1.9.20

Released: November 1, 2023

The Kotlin 1.9.20 release is out, the K2 compiler for all the targets is now in Beta, and Kotlin Multiplatform is now Stable. Additionally, here are some of the main highlights:

- New default hierarchy template for setting up multiplatform projects
- Full support for the Gradle configuration cache in Kotlin Multiplatform
- Custom memory allocator enabled by default in Kotlin/Native
- Performance improvements for the garbage collector in Kotlin/Native
- New and renamed targets in Kotlin/Wasm
- Support for the WASI API in the standard library for Kotlin/Wasm

You can also find a short overview of the updates in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 1.9.20 are available for:

IDE	Supported versions
IntelliJ IDEA	2023.1.x, 2023.2.x, 2023.x
Android Studio	Hedgehog (2023.1.1), Iguana (2023.2.1)

Starting from IntelliJ IDEA 2023.3.x and Android Studio Iguana (2023.2.1) Canary 15, the Kotlin plugin is automatically included and updated. All you need to do is update the Kotlin version in your projects.

New Kotlin K2 compiler updates

The Kotlin team at JetBrains is continuing to stabilize the new K2 compiler, which will bring major performance improvements, speed up new language feature development, unify all the platforms that Kotlin supports, and provide a better architecture for multiplatform projects.

K2 is currently in **Beta** for all targets. Read more in the release blog post

Support for Kotlin/Wasm

Since this release, the Kotlin/Wasm supports the new K2 compiler. Learn how to enable it in your project.

Preview kapt compiler plugin with K2

Support for K2 in the kapt compiler plugin is Experimental. Opt-in is required (see details below), and you should use it only for evaluation purposes.

In 1.9.20, you can try using the kapt compiler plugin with the K2 compiler. To use the K2 compiler in your project, add the following options to your `gradle.properties` file:

```
kotlin.experimental.tryK2=true
kapt.use.k2=true
```

Alternatively, you can enable K2 for kapt by completing the following steps:

1. In your `build.gradle.kts` file, set the language version to `2.0`.
2. In your `gradle.properties` file, add `kapt.use.k2=true`.

If you encounter any issues when using kapt with the K2 compiler, please report them to our issue tracker.

How to enable the Kotlin K2 compiler

Enable K2 in Gradle

To enable and test the Kotlin K2 compiler, use the new language version with the following compiler option:

```
-language-version 2.0
```

You can specify it in your `build.gradle.kts` file:

```
kotlin {
    sourceSets.all {
        languageSettings {
            languageVersion = "2.0"
        }
    }
}
```

Enable K2 in Maven

To enable and test the Kotlin K2 compiler, update the `<project/>` section of your `pom.xml` file:

```
<properties>
    <kotlin.compiler.languageVersion>2.0</kotlin.compiler.languageVersion>
</properties>
```

Enable K2 in IntelliJ IDEA

To enable and test the Kotlin K2 compiler in IntelliJ IDEA, go to **Settings** | **Build, Execution, Deployment** | **Compiler** | **Kotlin Compiler** and update the **Language Version** field to `2.0 (experimental)`.

Leave your feedback on the new K2 compiler

We would appreciate any feedback you may have!

- Provide your feedback directly to K2 developers on Kotlin Slack – get an invite and join the #k2-early-adopters channel.
- Report any problems you faced with the new K2 compiler on our issue tracker.
- Enable the Send usage statistics option to allow JetBrains to collect anonymous data about K2 usage.

Kotlin/JVM

Starting with version 1.9.20, the compiler can generate classes containing Java 21 bytecode.

Kotlin/Native

Kotlin 1.9.20 includes a Stable memory manager with the new memory allocator enabled by default, performance improvements for the garbage collector, and other updates:

- Custom memory allocator enabled by default
- Performance improvements for the garbage collector
- Incremental compilation of `klib` artifacts
- Managing library linkage issues
- Companion object initialization on class constructor calls
- Opt-in requirement for all cinterop declarations
- Custom message for linker errors
- Removal of the legacy memory manager
- Change to our target tiers policy

Custom memory allocator enabled by default

Kotlin 1.9.20 comes with the new memory allocator enabled by default. It's designed to replace the previous default allocator, `mimalloc`, to make garbage collection more efficient and improve the runtime performance of the Kotlin/Native memory manager.

The new custom allocator divides system memory into pages, allowing independent sweeping in consecutive order. Each allocation becomes a memory block within a page, and the page keeps track of block sizes. Different page types are optimized for various allocation sizes. The consecutive arrangement of memory blocks ensures efficient iteration through all allocated blocks.

When a thread allocates memory, it searches for a suitable page based on the allocation size. Threads maintain a set of pages for different size categories. Typically, the current page for a given size can accommodate the allocation. If not, the thread requests a different page from the shared allocation space. This page may already be available, require sweeping, or have to be created first.

The new allocator allows for multiple independent allocation spaces simultaneously, which will enable the Kotlin team to experiment with different page layouts to improve performance even further.

How to enable the custom memory allocator

Starting with Kotlin 1.9.20, the new memory allocator is the default. No additional setup is required.

If you experience high memory consumption, you can switch back to `mimalloc` or the system allocator with `-Xallocator=mimalloc` or `-Xallocator=std` in your Gradle build script. Please report such issues in YouTrack to help us improve the new memory allocator.

For the technical details of the new allocator's design, see this README.

Performance improvements for the garbage collector

The Kotlin team continues to improve the performance and stability of the new Kotlin/Native memory manager. This release brings a number of significant changes to the garbage collector (GC), including the following 1.9.20 highlights:

- Full parallel mark to reduce the pause time for the GC
- Tracking memory in big chunks to improve the allocation performance

Full parallel mark to reduce the pause time for the GC

Previously, the default garbage collector performed only a partial parallel mark. When the mutator thread was paused, it would mark the GC's start from its own roots, like thread–local variables and the call stack. Meanwhile, a separate GC thread was responsible for marking the start from global roots, as well as the roots of all mutators that were actively running the native code and therefore not paused.

This approach worked well in cases where there were a limited number of global objects and the mutator threads spent a considerable amount of time in a runnable state executing Kotlin code. However, this is not the case for typical iOS applications.

Now the GC uses a full parallel mark that combines paused mutators, the GC thread, and optional marker threads to process the mark queue. By default, the marking process is performed by:

- Paused mutators. Instead of processing their own roots and then being idle while not actively executing code, they contribute to the whole marking process.
- The GC thread. This ensures that at least one thread will perform marking.

This new approach makes the marking process more efficient, reducing the pause time of the GC.

Tracking memory in big chunks to improve the allocation performance

Previously, the GC scheduler tracked the allocation of each object individually. However, neither the new default custom allocator nor the `mimalloc` memory allocator allocates separate storage for each object; they allocate large areas for several objects at once.

In Kotlin 1.9.20, the GC tracks areas instead of individual objects. This speeds up the allocation of small objects by reducing the number of tasks performed on each allocation and, therefore, helps to minimize the garbage collector's memory usage.

Incremental compilation of klib artifacts

> This feature is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.9.20 introduces a new compilation time optimization for Kotlin/Native. The compilation of `klib` artifacts into native code is now partially incremental.

When compiling Kotlin source code into native binary in debug mode, the compilation goes through two stages:

1. Source code is compiled into `klib` artifacts.
2. `klib` artifacts, along with dependencies, are compiled into a binary.

To optimize the compilation time in the second stage, the team has already implemented compiler caches for dependencies. They are compiled into native code only once, and the result is reused every time a binary is compiled. But `klib` artifacts built from project sources were always fully recompiled into native code at every project change.

With the new incremental compilation, if the project module change causes only a partial recompilation of source code into `klib` artifacts, just a part of the `klib` is further recompiled into a binary.

To enable incremental compilation, add the following option to your `gradle.properties` file:

```
kotlin.incremental.native=true
```

If you face any issues, report such cases to YouTrack.

Managing library linkage issues

This release improves the way the Kotlin/Native compiler handles linkage issues in Kotlin libraries. Error messages now include more readable declarations as they use signature names instead of hashes, helping you find and fix the issue more easily. Here's an example:

```
No function found for symbol
'org.samples/MyClass.removedFunction|removedFunction(kotlin.Int;kotlin.String){}[0]'
```

The Kotlin/Native compiler detects linkage issues between third-party Kotlin libraries and reports errors at runtime. You might face such issues if the author of one third-party Kotlin library makes an incompatible change in experimental APIs that another third-party Kotlin library consumes.

Starting with Kotlin 1.9.20, the compiler detects linkage issues in silent mode by default. You can adjust this setting in your projects:

- If you want to record these issues in your compilation logs, enable warnings with the `-Xpartial-linkage-loglevel=WARNING` compiler option.
- It's also possible to raise the severity of reported warnings to compilation errors with `-Xpartial-linkage-loglevel=ERROR`. In this case, the compilation fails, and you get all the errors in the compilation log. Use this option to examine the linkage issues more closely.

```
// An example of passing compiler options in a Gradle build file:
kotlin {
    macosX64("native") {
        binaries.executable()

        compilations.configureEach {
            compilerOptions.configure {
                // To report linkage issues as warnings:
                freeCompilerArgs.add("-Xpartial-linkage-loglevel=WARNING")

                // To raise linkage warnings to errors:
                freeCompilerArgs.add("-Xpartial-linkage-loglevel=ERROR")
            }
        }
    }
}
```

If you face unexpected problems with this feature, you can always opt out with the `-Xpartial-linkage=disable` compiler option. Don't hesitate to report such cases to our issue tracker.

Companion object initialization on class constructor calls

Starting with Kotlin 1.9.20, the Kotlin/Native backend calls static initializers for companion objects in class constructors:

```
class Greeting {
    companion object {
        init {
            print("Hello, Kotlin!")
        }
    }
}

fun main() {
    val start = Greeting() // Prints "Hello, Kotlin!"
}
```

The behavior is now unified with Kotlin/JVM, where a companion object is initialized when the corresponding class matching the semantics of a Java static initializer is loaded (resolved).

Now that the implementation of this feature is more consistent between platforms, it's easier to share code in Kotlin Multiplatform projects.

Opt-in requirement for all cinterop declarations

Starting with Kotlin 1.9.20, all Kotlin declarations generated by the `cinterop` tool from C and Objective-C libraries, like libcurl and libxml, are marked with `@ExperimentalForeignApi`. If the opt-in annotation is missing, your code won't compile.

This requirement reflects the Experimental status of the import of C and Objective-C libraries. We recommend that you confine its use to specific areas in your projects. This will make your migration easier once we begin stabilizing the import.

> As for native platform libraries shipped with Kotlin/Native (like Foundation, UIKit, and POSIX), only some of their APIs need an opt-in with `@ExperimentalForeignApi`. In such cases, you get a warning with an opt-in requirement.

Custom message for linker errors

If you're a library author, you can now help your users resolve linker errors with custom messages.

If your Kotlin library depends on C or Objective-C libraries, for example, using the CocoaPods integration, its users need to have these dependent libraries locally on the machine or configure them explicitly in the project build script. If this was not the case, users used to get a confusing "Framework not found" message.

You can now provide a specific instruction or a link in the compilation failure message. To do that, pass the `-Xuser-setup-hint` compiler option to `cinterop` or add a `userSetupHint=message` property to your `.def` file.

Removal of the legacy memory manager

The new memory manager was introduced in Kotlin 1.6.20 and became the default in 1.7.20. Since then, it has been receiving further updates and performance improvements and has become Stable.

The time has come to complete the deprecation cycle and remove the legacy memory manager. If you're still using it, remove the `kotlin.native.binary.memoryModel=strict` option from your `gradle.properties` and follow our Migration guide to make the necessary changes.

Change to our target tiers policy

We've decided to upgrade the requirements for tier 1 support. The Kotlin team is now committed to providing source and binary compatibility between compiler releases for targets eligible for tier 1. They must also be regularly tested with CI tools to be able to compile and run. Currently, tier 1 includes the following targets for macOS hosts:

- `macosX64`
- `macosArm64`
- `iosSimulatorArm64`
- `iosX64`

In Kotlin 1.9.20, we've also removed a number of previously deprecated targets, namely:

- `iosArm32`
- `watchosX86`
- `wasm32`
- `mingwX86`
- `linuxMips32`
- `linuxMipsel32`

See the full list of currently supported targets.

Kotlin Multiplatform

Kotlin 1.9.20 focuses on the stabilization of Kotlin Multiplatform and makes new steps in improving developer experience with the new project wizards and other notable features:

- Kotlin Multiplatform is Stable
- Template for configuring multiplatform projects
- New project wizard
- Full support for the Gradle Configuration cache
- Easier configuration of new standard library versions in Gradle
- Default support for third-party cinterop libraries
- Support for Kotlin/Native compilation caches in Compose Multiplatform projects
- Compatibility guidelines

Kotlin Multiplatform is Stable

The 1.9.20 release marks an important milestone in the evolution of Kotlin: Kotlin Multiplatform has finally become Stable. This means that the technology is safe to use in your projects and 100% ready for production. It also means that further development of Kotlin Multiplatform will continue according to our strict backward compatibility rules.

Please note that some advanced features of Kotlin Multiplatform are still evolving. When using them, you'll receive a warning that describes the current stability status of the feature you're using. Before using any experimental functionality in IntelliJ IDEA,
you'll need to enable it explicitly in **Settings** | **Advanced Settings** | **Kotlin** | **Experimental Multiplatform**.

- Visit the Kotlin blog to learn more about the Kotlin Multiplatform stabilization and future plans.
- Check out the Multiplatform compatibility guide to see what significant changes were made on the way to stabilization.
- Read about the mechanism of expected and actual declarations, an important part of Kotlin Multiplatform that was also partially stabilized in this release.

Template for configuring multiplatform projects

Starting with Kotlin 1.9.20, the Kotlin Gradle plugin automatically creates shared source sets for popular multiplatform scenarios. If your project setup is one of them, you don't need to configure the source set hierarchy manually. Just explicitly specify the targets necessary for your project.

Setup is now easier thanks to the default hierarchy template, a new feature of the Kotlin Gradle plugin. It's a predefined template of a source set hierarchy built into the plugin. It includes intermediate source sets that Kotlin automatically creates for the targets you declared. See the full template.

Create your project easier

Consider a multiplatform project that targets both Android and iPhone devices and is developed on an Apple silicon MacBook. Compare how this project is set up between different versions of Kotlin:

Kotlin 1.9.0 and earlier (a standard setup)

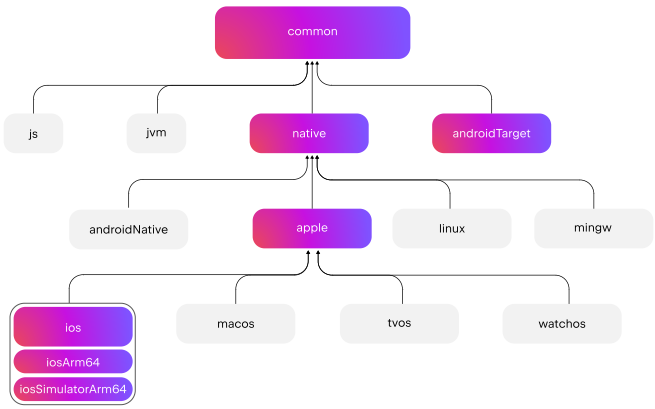
```
kotlin {
    androidTarget()
    iosArm64()
    iosSimulatorArm64()

    sourceSets {
        val commonMain by getting

        val iosMain by creating {
            dependsOn(commonMain)
        }

        val iosArm64Main by getting {
            dependsOn(iosMain)
        }

        val iosSimulatorArm64Main by getting
{
            dependsOn(iosMain)
        }
    }
}
```



Kotlin 1.9.20

```
kotlin {
    androidTarget()
    iosArm64()
    iosSimulatorArm64()

    // The iosMain source set is created
automatically
}
```

Notice how the use of the default hierarchy template considerably reduces the amount of boilerplate code needed to set up your project.

When you declare the `androidTarget`, `iosArm64`, and `iosSimulatorArm64` targets in your code, the Kotlin Gradle plugin finds suitable shared source sets from the template and creates them for you. The resulting hierarchy looks like this:

An example of the default target hierarchy in use

Green source sets are actually created and included in the project, while gray ones from the default template are ignored.

Use completion for source sets

To make it easier to work with the created project structure, IntelliJ IDEA now provides completion for source sets created with the default hierarchy template:

Kotlin also warns you if you attempt to access a source set that doesn't exist because you haven't declared the respective target. In the example below, there is no JVM target (only `androidTarget`, which is not the same). But let's try to use the `jvmMain` source set and see what happens:

```
kotlin {
    androidTarget()
    iosArm64()
    iosSimulatorArm64()

    sourceSets {
        jvmMain {
        }
    }
}
```

In this case, Kotlin reports a warning in the build log:

```
w: Accessed 'source set jvmMain' without registering the jvm target:
  kotlin {
      jvm() /* ← register the 'jvm' target */

      sourceSets.jvmMain.dependencies {

      }
  }
```

Set up the target hierarchy

Starting with Kotlin 1.9.20, the default hierarchy template is automatically enabled. In most cases, no additional setup is required.

However, if you're migrating existing projects created before 1.9.20, you might encounter a warning if you had previously introduced intermediate sources manually with `dependsOn()` calls. To solve this issue, do the following:

- If your intermediate source sets are currently covered by the default hierarchy template, remove all manual `dependsOn()` calls and source sets created with `by creating` constructions.

  To check the list of all default source sets, see the full hierarchy template.

- If you want to have additional source sets that the default hierarchy template doesn't provide, for example, one that shares code between a macOS and a JVM target, adjust the hierarchy by reapplying the template explicitly with `applyDefaultHierarchyTemplate()` and configuring additional source sets manually as usual with `dependsOn()`:

  ```
  kotlin {
      jvm()
      macosArm64()
      iosArm64()
      iosSimulatorArm64()

      // Apply the default hierarchy explicitly. It'll create, for example, the iosMain source set:
      applyDefaultHierarchyTemplate()

      sourceSets {
          // Create an additional jvmAndMacos source set
          val jvmAndMacos by creating {
              dependsOn(commonMain.get())
          }

          macosArm64Main.get().dependsOn(jvmAndMacos)
          jvmMain.get().dependsOn(jvmAndMacos)
      }
  }
  ```

- If there are already source sets in your project that have the exact same names as those generated by the template but that are shared among different sets of targets, there's currently no way to modify the default `dependsOn` relations between the template's source sets.

  One option you have here is to find different source sets for your purposes, either in the default hierarchy template or ones that have been manually created. Another is to opt out of the template completely.

  To opt out, add `kotlin.mpp.applyDefaultHierarchyTemplate=false` to your `gradle.properties` and configure all other source sets manually.

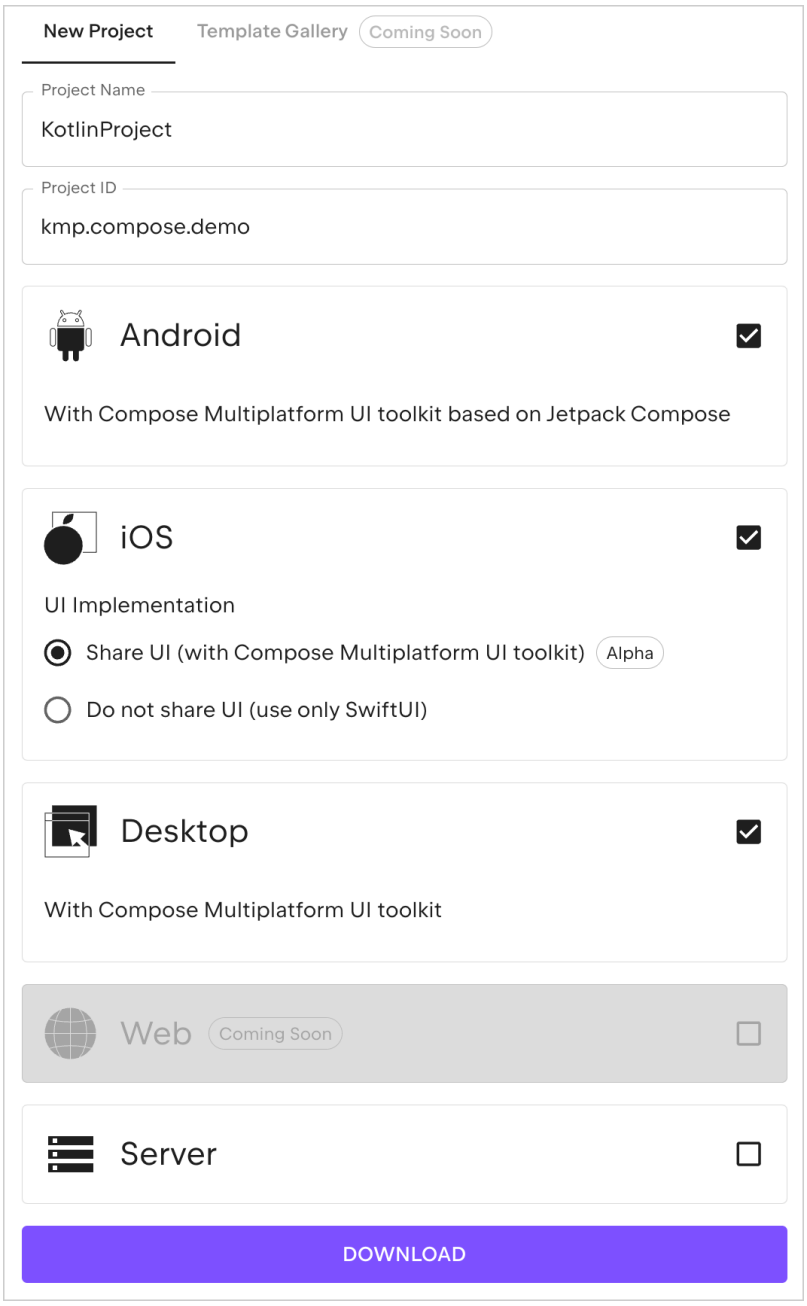
  We're currently working on an API for creating your own hierarchy templates to simplify the setup process in such cases.

See the full hierarchy template

When you declare the targets to which your project compiles, the plugin picks the shared source sets from the template accordingly and creates them in your project.

Default hierarchy template

> This example only shows the production part of the project, omitting the `Main` suffix (for example, using `common` instead of `commonMain`). However, everything is the same for `*Test` sources as well.



New project wizard

The JetBrains team is introducing a new way of creating cross-platform projects – the Kotlin Multiplatform web wizard.

This first implementation of the new Kotlin Multiplatform wizard covers the most popular Kotlin Multiplatform use cases. It incorporates all the feedback about previous project templates and makes the architecture as robust and reliable as possible.

The new wizard has a distributed architecture that allows us to have a unified backend and different frontends, with the web version being the first step. We're considering both implementing an IDE version and creating a command-line tool in the future. On the web, you always get the latest version of the wizard, while in IDEs you'll need to wait for the next release.

With the new wizard, project setup is easier than ever. You can tailor your projects to your needs by choosing the target platforms for mobile, server, and desktop development. We also plan to add web development in future releases.

Multiplatform web wizard

The new project wizard is now the preferred way to create cross-platform projects with Kotlin. Since 1.9.20, the Kotlin plugin no longer provides a **Kotlin Multiplatform** project wizard in IntelliJ IDEA.

The new wizard will guide you easily through the initial setup, making the onboarding process much smoother. If you encounter any issues, please report them to YouTrack to help us improve your experience with the wizard.

Create a project

Full support for the Gradle configuration cache in Kotlin Multiplatform

Previously, we introduced a preview of the Gradle configuration cache, which was available for Kotlin multiplatform libraries. With 1.9.20, the Kotlin Multiplatform plugin takes a step further.

It now supports the Gradle configuration cache in the Kotlin CocoaPods Gradle plugin, as well as in the integration tasks that are necessary for Xcode builds, like `embedAndSignAppleFrameworkForXcode`.

Now all multiplatform projects can take advantage of the improved build time. The Gradle configuration cache speeds up the build process by reusing the results of the configuration phase for subsequent builds. For more details and setup instructions, see the Gradle documentation.

Easier configuration of new standard library versions in Gradle

When you create a multiplatform project, a dependency for the standard library (`stdlib`) is added automatically to each source set. This is the easiest way to get started with your multiplatform projects.

Previously, if you wanted to configure a dependency on the standard library manually, you needed to configure it for each source set individually. From `kotlin-stdlib:1.9.20` onward, you only need to configure the dependency **once** in the `commonMain` root source set:

Standard library version 1.9.10 and earlier

```
kotlin {
    sourceSets {
        // For the common source set
        val commonMain by getting {
            dependencies {

implementation("org.jetbrains.kotlin:kotlin-
stdlib-common:1.9.10")
            }
        }

        // For the JVM source set
        val jvmMain by getting {
            dependencies {

implementation("org.jetbrains.kotlin:kotlin-
stdlib:1.9.10")
            }
        }

        // For the JS source set
        val jsMain by getting {
            dependencies {

implementation("org.jetbrains.kotlin:kotlin-
stdlib-js:1.9.10")
            }
        }
    }
}
```

Standard library version 1.9.20

```
kotlin {
    sourceSets {
        commonMain {
            dependencies {

implementation("org.jetbrains.kotlin:kotlin-
stdlib:1.9.20")
            }
        }
    }
}
```

This change was made possible by including new information in the Gradle metadata of the standard library. This allows Gradle to automatically resolve the correct standard library artifacts for the other source sets.

Default support for third-party cinterop libraries

Kotlin 1.9.20 adds default support (rather than support by opt-in) for all cinterop dependencies in projects that have the Kotlin CocoaPods Gradle plugin applied.

This means you can now share more native code without being limited by platform–specific dependencies. For example, you can add dependencies on Pod libraries to the `iosMain` shared source set.

Previously, this only worked with platform-specific libraries shipped with a Kotlin/Native distribution (like Foundation, UIKit, and POSIX). All third-party Pod libraries are now available in shared source sets by default. You no longer need to specify a separate Gradle property to support them.

Support for Kotlin/Native compilation caches in Compose Multiplatform projects

This release resolves a compatibility issue with the Compose Multiplatform compiler plugin, which mostly affected Compose Multiplatform projects for iOS.

To work around this issue, you had to disable caching by using the `kotlin.native.cacheKind=none` Gradle property. However, this workaround came at a performance cost: It slowed down compilation time as caching didn't work in the Kotlin/Native compiler.

Now that the issue is fixed, you can remove `kotlin.native.cacheKind=none` from your `gradle.properties` file and enjoy the improved compilation times in your Compose Multiplatform projects.

For more tips on improving compilation times, see the Kotlin/Native documentation.

Compatibility guidelines

When configuring your projects, check the Kotlin Multiplatform Gradle plugin's compatibility with the available Gradle, Xcode, and Android Gradle plugin (AGP) versions:

Kotlin Multiplatform Gradle plugin	Gradle	Android Gradle plugin	Xcode
1.9.20	7.5 and later	7.4.2–8.2	15.0. See details below

As of this release, the recommended version of Xcode is 15.0. Libraries delivered with Xcode 15.0 are fully supported, and you can access them from anywhere in your Kotlin code.

However, XCode 14.3 should still work in the majority of cases. Keep in mind that if you use version 14.3 on your local machine, libraries delivered with Xcode 15 will be visible but not accessible.

Kotlin/Wasm

In 1.9.20, Kotlin Wasm reached the Alpha level of stability.

- Compatibility with Wasm GC phase 4 and final opcodes
- New `wasm-wasi` target, and the renaming of the `wasm` target to `wasm-js`
- Support for the WASI API in standard library
- Kotlin/Wasm API improvements

Kotlin Wasm is Alpha. It is subject to change at any time. Use it only for evaluation purposes.

We would appreciate your feedback on it in YouTrack.

Compatibility with Wasm GC phase 4 and final opcodes

Wasm GC moves to the final phase and it requires updates of opcodes – constant numbers used in the binary representation. Kotlin 1.9.20 supports the latest opcodes, so we strongly recommend that you update your Wasm projects to the latest version of Kotlin. We also recommend using the latest versions of browsers with the Wasm environment:

- Version 119 or newer for Chrome and Chromium–based browsers.
- Version 119 or newer for Firefox. Note that in Firefox 119, you need to turn on Wasm GC manually.

New wasm-wasi target, and the renaming of the wasm target to wasm-js

In this release, we're introducing a new target for Kotlin/Wasm – `wasm-wasi`. We're also renaming the `wasm` target to `wasm-js`. In the Gradle DSL, these targets are available as `wasmWasi {}` and `wasmJs {}`, respectively.

To use these targets in your project, update the `build.gradle.kts` file:

```
kotlin {
    wasmWasi {
        // ...
    }
    wasmJs {
        // ...
    }
}
```

The previously introduced `wasm {}` block has been deprecated in favor of `wasmJs {}`.

To migrate your existing Kotlin/Wasm project, do the following:

- In the `build.gradle.kts` file, rename the `wasm {}` block to `wasmJs {}`.
- In your project structure, rename the `wasmMain` directory to `wasmJsMain`.

Support for the WASI API in the standard library

In this release, we have included support for WASI, a system interface for the Wasm platform. WASI support makes it easier for you to use Kotlin/Wasm outside of browsers, for example in server–side applications, by offering a standardized set of APIs for accessing system resources. In addition, WASI provides capability–based security – another layer of security when accessing external resources.

To run Kotlin/Wasm applications, you need a VM that supports Wasm Garbage Collection (GC), for example, Node.js or Deno. Wasmtime, WasmEdge, and others are still working towards full Wasm GC support.

To import a WASI function, use the `@WasmImport` annotation:

```
import kotlin.wasm.WasmImport

@WasmImport("wasi_snapshot_preview1", "clock_time_get")
private external fun wasiRawClockTimeGet(clockId: Int, precision: Long, resultPtr: Int): Int
```

You can find a full example in our GitHub repository.

It isn't possible to use interoperability with JavaScript, while targeting `wasmWasi`.

Kotlin/Wasm API improvements

This release delivers several quality-of-life improvements to the Kotlin/Wasm API. For example, you're no longer required to return a value for DOM event listeners:

Before 1.9.20

```
fun main() {
    window.onload = {
        document.body?.sayHello()
        null
    }
}
```

In 1.9.20

```
fun main() {
    window.onload = { document.body?.sayHello() }
}
```

Gradle

Kotlin 1.9.20 is fully compatible with Gradle 6.8.3 through 8.1. You can also use Gradle versions up to the latest Gradle release, but if you do, keep in mind that you might encounter deprecation warnings or some new Gradle features might not work.

This version brings the following changes:

- Support for test fixtures to access internal declarations
- New property to configure paths to Konan directories
- New build report metrics for Kotlin/Native tasks

Support for test fixtures to access internal declarations

In Kotlin 1.9.20, if you use Gradle's `java-test-fixtures` plugin, then your test fixtures now have access to `internal` declarations within main source set classes. In addition, any test sources can also see any `internal` declarations within test fixtures classes.

New property to configure paths to Konan directories

In Kotlin 1.9.20, the `konan.data.dir` Gradle property is available to customize your path to the `~/.konan` directory so that you don't have to configure it through the environment variable `KONAN_DATA_DIR`.

Alternatively, you can use the `-Xkonan-data-dir` compiler option to configure your custom path to the `~/.konan` directory via the `cinterop` and `konanc` tools.

New build report metrics for Kotlin/Native tasks

In Kotlin 1.9.20, Gradle build reports now include metrics for Kotlin/Native tasks. Here is an example of a build report containing these metrics:

```
Total time for Kotlin tasks: 20.81 s (93.1 % of all tasks time)
Time   |% of Kotlin time|Task
15.24 s|73.2 %          |:compileCommonMainKotlinMetadata
5.57 s |26.8 %          |:compileNativeMainKotlinMetadata

Task ':compileCommonMainKotlinMetadata' finished in 15.24 s
Task info:
  Kotlin language version: 2.0
Time metrics:
  Total Gradle task time: 15.24 s
  Spent time before task action: 0.16 s
  Task action before worker execution: 0.21 s
  Run native in process: 2.70 s
    Run entry point: 2.64 s
Size metrics:
  Start time of task action: 2023-07-27T11:04:17

Task ':compileNativeMainKotlinMetadata' finished in 5.57 s
Task info:
  Kotlin language version: 2.0
Time metrics:
  Total Gradle task time: 5.57 s
  Spent time before task action: 0.04 s
  Task action before worker execution: 0.02 s
  Run native in process: 1.48 s
    Run entry point: 1.47 s
Size metrics:
  Start time of task action: 2023-07-27T11:04:32
```

In addition, the `kotlin.experimental.tryK2` build report now includes any Kotlin/Native tasks that were compiled and lists the language version used:

```
##### 'kotlin.experimental.tryK2' results #####
:lib:compileCommonMainKotlinMetadata: 2.0 language version
:lib:compileKotlinJvm: 2.0 language version
:lib:compileKotlinIosArm64: 2.0 language version
:lib:compileKotlinIosSimulatorArm64: 2.0 language version
:lib:compileKotlinLinuxX64: 2.0 language version
:lib:compileTestKotlinJvm: 2.0 language version
:lib:compileTestKotlinIosSimulatorArm64: 2.0 language version
:lib:compileTestKotlinLinuxX64: 2.0 language version
##### 100% (8/8) tasks have been compiled with Kotlin 2.0 #####
```

If you use Gradle 8.0, you might come across some problems with build reports, especially when Gradle configuration caching is enabled. This is a known issue, which is fixed in Gradle 8.1 and later.

Standard library

In Kotlin 1.9.20, the Kotlin/Native standard library becomes Stable, and there are some new features:

- Replacement of the Enum class values generic function
- Improved performance of HashMap operations in Kotlin/JS

Replacement of the Enum class values generic function

> This feature is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

In Kotlin 1.9.0, the `entries` property for enum classes became Stable. The `entries` property is a modern and performant replacement for the synthetic `values()` function. As part of Kotlin 1.9.20, there is a replacement for the generic `enumValues<T>()` function: `enumEntries<T>()`.

> The `enumValues<T>()` function is still supported, but we recommend that you use the `enumEntries<T>()` function instead because it has less performance impact. Every time you call `enumValues<T>()`, a new array is created, whereas whenever you call `enumEntries<T>()`, the same list is returned each time, which is far more efficient.

For example:

```
enum class RGB { RED, GREEN, BLUE }

@OptIn(ExperimentalStdlibApi::class)
inline fun <reified T : Enum<T>> printAllValues() {
    print(enumEntries<T>().joinToString { it.name })
}

printAllValues<RGB>()
// RED, GREEN, BLUE
```

How to enable the enumEntries function

To try this feature, opt in with `@OptIn(ExperimentalStdlibApi)` and use language version 1.9 or later. If you use the latest version of the Kotlin Gradle plugin, you don't need to specify the language version to test the feature.

The Kotlin/Native standard library becomes Stable

In Kotlin 1.9.0, we explained the actions we've taken to bring the Kotlin/Native standard library closer to our goal of stabilization. In Kotlin 1.9.20, we finally conclude this work and make the Kotlin/Native standard library Stable. Here are some highlights from this release:

- The `Vector128` class was moved from the `kotlin.native` package to the `kotlinx.cinterop` package.
- The opt-in requirement level for `ExperimentalNativeApi` and `NativeRuntimeApi` annotations, which were introduced as part of Kotlin 1.9.0, has been raised from `WARNING` to `ERROR`.
- Kotlin/Native collections now detect concurrent modifications, for example, in the `ArrayList` and `HashMap` collections.
- The `printStackTrace()` function from the `Throwable` class now prints to `STDERR` instead of `STDOUT`.

> The output format of `printStackTrace()` isn't Stable and is subject to change.

Improvements to the Atomics API

In Kotlin 1.9.0, we said that the Atomics API would be ready to become Stable when the Kotlin/Native standard library becomes Stable. Kotlin 1.9.20 includes the following additional changes:

- Experimental `AtomicIntArray`, `AtomicLongArray`, and `AtomicArray<T>` classes are introduced. These new classes are designed specifically to be consistent with Java's atomic arrays so that in the future, they can be included in the common standard library.

  > The `AtomicIntArray`, `AtomicLongArray`, and `AtomicArray<T>` classes are Experimental. They may be dropped or changed at any time. To try them, opt in with `@OptIn(ExperimentalStdlibApi)`. Use them only for evaluation purposes. We would appreciate your feedback in YouTrack.

- In the `kotlin.native.concurrent` package, the Atomics API that was deprecated in Kotlin 1.9.0 with deprecation level `WARNING` has had its deprecation level raised to `ERROR`.
- In the `kotlin.concurrent` package, member functions of the `AtomicInt` and `AtomicLong` classes that had deprecation level: `ERROR`, have been removed.
- All member functions of the `AtomicReference` class now use atomic intrinsic functions.

For more information on all of the changes in Kotlin 1.9.20, see our YouTrack ticket.

Improved performance of HashMap operations in Kotlin/JS

Kotlin 1.9.20 improves the performance of `HashMap` operations and reduces their memory footprint in Kotlin/JS. Internally, Kotlin/JS has changed its internal implementation to open addressing. This means that you should see performance improvements when you:

- Insert new elements into a `HashMap`.
- Search for existing elements in a `HashMap`.
- Iterate through keys or values in a `HashMap`.

Documentation updates

The Kotlin documentation has received some notable changes:

- The JVM Metadata API reference – Explore how you can parse metadata with Kotlin/JVM.
- Time measurement guide – Learn how to calculate and measure time in Kotlin.
- Improved Collections chapter in the tour of Kotlin – Learn the fundamentals of the Kotlin programming language with chapters including both theory and practice.
- Definitely non-nullable types – Learn about definitely non-nullable generic types.
- Improved Arrays page – Learn about arrays and when to use them.
- Expected and actual declarations in Kotlin Multiplatform – Learn about the Kotlin mechanism of expected and actual declarations in Kotlin Multiplatform.

Install Kotlin 1.9.20

Check the IDE version

IntelliJ IDEA 2023.1.x and 2023.2.x automatically suggest updating the Kotlin plugin to version 1.9.20. IntelliJ IDEA 2023.3 will include the Kotlin 1.9.20 plugin.

Android Studio Hedgehog (231) and Iguana (232) will support Kotlin 1.9.20 in their upcoming releases.

The new command-line compiler is available for download on the GitHub release page.

Configure Gradle settings

To download Kotlin artifacts and dependencies, update your `settings.gradle(.kts)` file to use the Maven Central repository:

```
pluginManagement {
    repositories {
        mavenCentral()
        gradlePluginPortal()
    }
}
```

If the repository is not specified, Gradle uses the sunset JCenter repository, which could lead to issues with Kotlin artifacts.

What's new in Kotlin 1.9.0

Release date: July 6, 2023

The Kotlin 1.9.0 release is out and the K2 compiler for the JVM is now in **Beta**. Additionally, here are some of the main highlights:

- New Kotlin K2 compiler updates
- Stable replacement of the enum class values function
- Stable `..<` operator for open-ended ranges
- New common function to get regex capture group by name
- New path utility to create parent directories
- Preview of the Gradle configuration cache in Kotlin Multiplatform
- Changes to Android target support in Kotlin Multiplatform
- Preview of custom memory allocator in Kotlin/Native
- Library linkage in Kotlin/Native
- Size-related optimizations in Kotlin/Wasm

You can also find a short overview of the updates in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 1.9.0 are available for:

IDE	Supported versions
IntelliJ IDEA	2022.3.x, 2023.1.x
Android Studio	Giraffe (223), Hedgehog (231)*

*The Kotlin 1.9.0 plugin will be included with Android Studio Giraffe (223) and Hedgehog (231) in their upcoming releases.

The Kotlin 1.9.0 plugin will be included with IntelliJ IDEA 2023.2 in the upcoming releases.

To download Kotlin artifacts and dependencies, configure your Gradle settings to use the Maven Central Repository.

New Kotlin K2 compiler updates

The Kotlin team at JetBrains continues to stabilize the K2 compiler, and the 1.9.0 release introduces further advancements. The K2 compiler for the JVM is now in **Beta**.

There's now also basic support for Kotlin/Native and multiplatform projects.

Compatibility of the kapt compiler plugin with the K2 compiler

You can use the kapt plugin in your project along with the K2 compiler, but with some restrictions. Despite setting `languageVersion` to `2.0`, the kapt compiler plugin still utilizes the old compiler.

If you execute the kapt compiler plugin within a project where `languageVersion` is set to `2.0`, kapt will automatically switch to `1.9` and disable specific version compatibility checks. This behavior is equivalent to including the following command arguments:

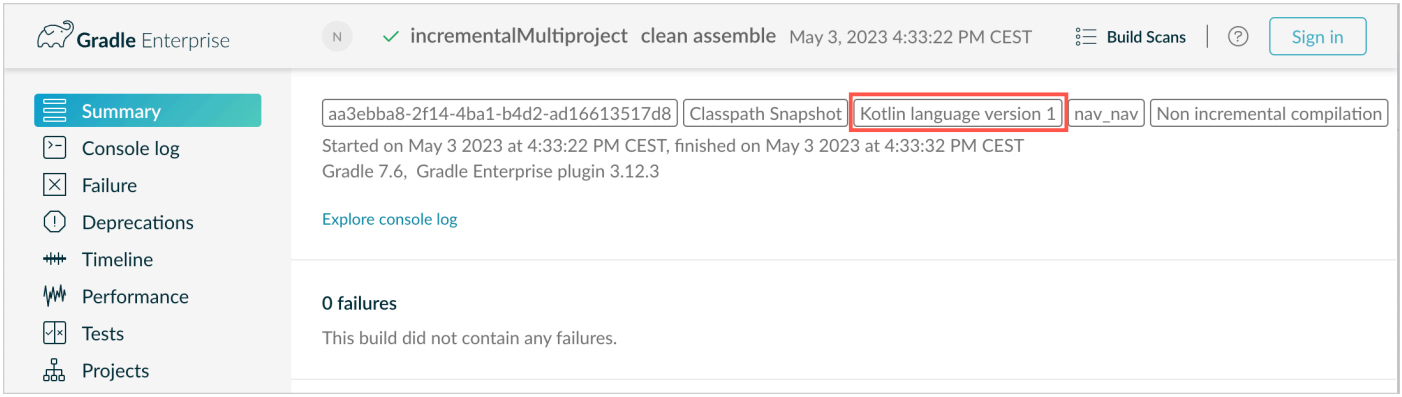
- `-Xskip-metadata-version-check`
- `-Xskip-prerelease-check`
- `-Xallow-unstable-dependencies`

These checks are exclusively disabled for kapt tasks. All other compilation tasks will continue to utilize the new K2 compiler.

If you encounter any issues when using kapt with the K2 compiler, please report them to our issue tracker.

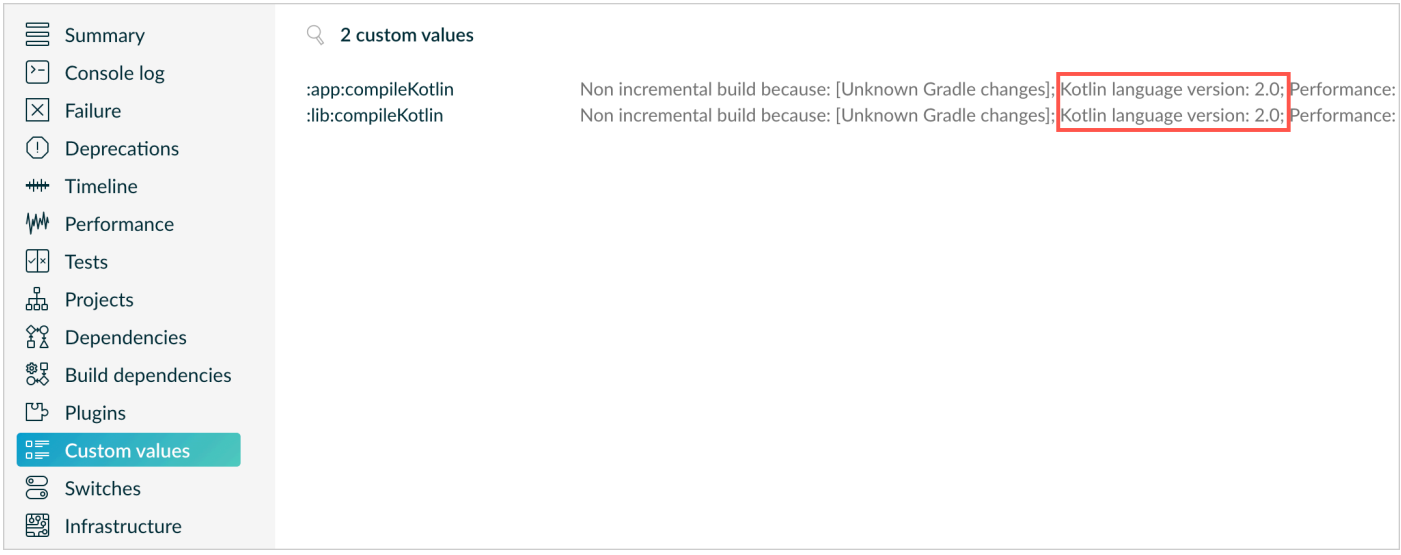
Try the K2 compiler in your project

Starting with 1.9.0 and until the release of Kotlin 2.0, you can easily test the K2 compiler by adding the `kotlin.experimental.tryK2=true` Gradle property to your `gradle.properties` file. You can also run the following command:



```
./gradlew assemble -Pkotlin.experimental.tryK2=true
```

This Gradle property automatically sets the language version to 2.0 and updates the build report with the number of Kotlin tasks compiled using the K2 compiler compared to the current compiler:



```
##### 'kotlin.experimental.tryK2' results (Kotlin/Native not checked) #####
:lib:compileKotlin: 2.0 language version
:app:compileKotlin: 2.0 language version
##### 100% (2/2) tasks have been compiled with Kotlin 2.0 #####
```

Gradle build reports

Gradle build reports now show whether the current or the K2 compiler was used to compile the code. In Kotlin 1.9.0, you can see this information in your Gradle build scans:

Gradle build scan - K1

Gradle build scan - K2

You can also find the Kotlin version used in the project right in the build report:

```
Task info:
  Kotlin language version: 1.9
```

If you use Gradle 8.0, you might come across some problems with build reports, especially when Gradle configuration caching is enabled. This is a known issue, fixed in Gradle 8.1 and later.

Current K2 compiler limitations

Enabling K2 in your Gradle project comes with certain limitations that can affect projects using Gradle versions below 8.3 in the following cases:

- Compilation of source code from `buildSrc`.
- Compilation of Gradle plugins in included builds.
- Compilation of other Gradle plugins if they are used in projects with Gradle versions below 8.3.
- Building Gradle plugin dependencies.

If you encounter any of the problems mentioned above, you can take the following steps to address them:

- Set the language version for `buildSrc`, any Gradle plugins, and their dependencies:

```
kotlin {
    compilerOptions {
        languageVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9)
        apiVersion.set(org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9)
    }
}
```

- Update the Gradle version in your project to 8.3 when it becomes available.

Leave your feedback on the new K2 compiler

We'd appreciate any feedback you may have!

- Provide your feedback directly to K2 developers Kotlin's Slack – get an invite and join the #k2-early-adopters channel.
- Report any problems you've faced with the new K2 compiler on our issue tracker.
- Enable the **Send usage statistics** option to allow JetBrains to collect anonymous data about K2 usage.

Language

In Kotlin 1.9.0, we're stabilizing some new language features that were introduced earlier:

- Replacement of the enum class values function
- Data object symmetry with data classes
- Support for secondary constructors with bodies in inline value classes

Stable replacement of the enum class values function

In 1.8.20, the `entries` property for enum classes was introduced as an Experimental feature. The `entries` property is a modern and performant replacement for the synthetic `values()` function. In 1.9.0, the `entries` property is Stable.

> The `values()` function is still supported, but we recommend that you use the `entries` property instead.

```
enum class Color(val colorName: String, val rgb: String) {
    RED("Red", "#FF0000"),
    ORANGE("Orange", "#FF7F00"),
    YELLOW("Yellow", "#FFFF00")
}

fun findByRgb(rgb: String): Color? = Color.entries.find { it.rgb == rgb }
```

For more information about the `entries` property for enum classes, see What's new in Kotlin 1.8.20.

Stable data objects for symmetry with data classes

Data object declarations, which were introduced in Kotlin 1.8.20, are now Stable. This includes the functions added for symmetry with data classes: `toString()`, `equals()`, and `hashCode()`.

This feature is particularly useful with `sealed` hierarchies (like a `sealed class` or `sealed interface` hierarchy), because `data object` declarations can be used conveniently alongside `data class` declarations. In this example, declaring `EndOfFile` as a `data object` instead of a plain `object` means that it automatically has a `toString()` function without the need to override it manually. This maintains symmetry with the accompanying data class definitions.

```
sealed interface ReadResult
data class Number(val number: Int) : ReadResult
data class Text(val text: String) : ReadResult
data object EndOfFile : ReadResult

fun main() {
    println(Number(7)) // Number(number=7)
    println(EndOfFile) // EndOfFile
}
```

For more information, see What's new in Kotlin 1.8.20.

Support for secondary constructors with bodies in inline value classes

Starting with Kotlin 1.9.0, the use of secondary constructors with bodies in inline value classes is available by default:

```
@JvmInline
value class Person(private val fullName: String) {
    // Allowed since Kotlin 1.4.30:
    init {
        check(fullName.isNotBlank()) {
            "Full name shouldn't be empty"
        }
    }
    // Allowed by default since Kotlin 1.9.0:
    constructor(name: String, lastName: String) : this("$name $lastName") {
        check(lastName.isNotBlank()) {
            "Last name shouldn't be empty"
        }
    }
}
```

Previously, Kotlin allowed only public primary constructors in inline classes. As a result, it was impossible to encapsulate underlying values or create an inline class that would represent some constrained values.

As Kotlin developed, these issues were fixed. Kotlin 1.4.30 lifted restrictions on `init` blocks and then Kotlin 1.8.20 came with a preview of secondary constructors with bodies. They are now available by default. Learn more about the development of Kotlin inline classes in this KEEP.

Kotlin/JVM

Starting with version 1.9.0, the compiler can generate classes with a bytecode version corresponding to JVM 20. In addition, the deprecation of the `JvmDefault` annotation and legacy `-Xjvm-default` modes continues.

Deprecation of JvmDefault annotation and legacy -Xjvm-default modes

Starting from Kotlin 1.5, the usage of the `JvmDefault` annotation has been deprecated in favor of the newer `-Xjvm-default` modes: `all` and `all-compatibility`. With the introduction of `JvmDefaultWithoutCompatibility` in Kotlin 1.4 and `JvmDefaultWithCompatibility` in Kotlin 1.6, these modes offer comprehensive control over the generation of `DefaultImpls` classes, ensuring seamless compatibility with older Kotlin code.

Consequently in Kotlin 1.9.0, the `JvmDefault` annotation no longer holds any significance and has been marked as deprecated, resulting in an error. It will eventually be removed from Kotlin.

Kotlin/Native

Among other improvements, this release brings further advancements to the Kotlin/Native memory manager that should enhance its robustness and performance:

- Preview of custom memory allocator
- Objective-C or Swift object deallocation hook on the main thread
- No object initialization when accessing constant values in Kotlin/Native
- Ability to configure standalone mode for iOS simulator tests
- Library linkage in Kotlin/Native

Preview of custom memory allocator

Kotlin 1.9.0 introduces the preview of a custom memory allocator. Its allocation system improves the runtime performance of the Kotlin/Native memory manager.

The current object allocation system in Kotlin/Native uses a general-purpose allocator that doesn't have the functionality for efficient garbage collection. To compensate, it maintains thread-local linked lists of all allocated objects before the garbage collector (GC) merges them into a single list, which can be iterated during sweeping. This approach comes with several performance downsides:

- The sweeping order lacks memory locality and often results in scattered memory access patterns, leading to potential performance issues.
- Linked lists require additional memory for each object, increasing memory usage, particularly when dealing with many small objects.
- The single list of allocated objects makes it challenging to parallelize sweeping, which can cause memory usage problems when mutator threads allocate objects faster than the GC thread can collect them.

To address these issues, Kotlin 1.9.0 introduces a preview of the custom allocator. It divides system memory into pages, allowing independent sweeping in consecutive order. Each allocation becomes a memory block within a page, and the page keeps track of block sizes. Different page types are optimized for various allocation sizes. The consecutive arrangement of memory blocks ensures efficient iteration through all allocated blocks.

When a thread allocates memory, it searches for a suitable page based on the allocation size. Threads maintain a set of pages for different size categories. Typically, the current page for a given size can accommodate the allocation. If not, the thread requests a different page from the shared allocation space. This page may already be available, require sweeping, or should be created first.

The new allocator allows having multiple independent allocation spaces simultaneously, which will allow the Kotlin team to experiment with different page layouts to improve performance even further.

For more information on the design of the new allocator, see this README.

How to enable

Add the `-Xallocator=custom` compiler option:

```
kotlin {
    macosX64("native") {
        binaries.executable()

        compilations.configureEach {
            compilerOptions.configure {
                freeCompilerArgs.add("-Xallocator=custom")
            }
        }
    }
}
```

Leave feedback

We would appreciate your feedback in YouTrack to improve the custom allocator.

Objective-C or Swift object deallocation hook on the main thread

Starting with Kotlin 1.9.0, the Objective-C or Swift object deallocation hook is called on the main thread if the object is passed to Kotlin there. The way the Kotlin/Native memory manager previously handled references to Objective-C objects could lead to memory leaks. We believe the new behavior should improve the robustness of the memory manager.

Consider an Objective-C object that is referenced in Kotlin code, for example, when passed as an argument, returned by a function, or retrieved from a collection. In this case, Kotlin creates its own object that holds the reference to the Objective-C object. When the Kotlin object gets deallocated, the Kotlin/Native runtime calls the `objc_release` function that releases that Objective-C reference.

Previously, the Kotlin/Native memory manager ran `objc_release` on a special GC thread. If it's the last object reference, the object gets deallocated. Issues could come up when Objective-C objects have custom deallocation hooks like the `dealloc` method in Objective-C or the `deinit` block in Swift, and these hooks expect to be called on a specific thread.

Since hooks for objects on the main thread usually expect to be called there, Kotlin/Native runtime now calls `objc_release` on the main thread as well. It should cover the cases when the Objective-C object was passed to Kotlin on the main thread, creating a Kotlin peer object there. This only works if the main dispatch queue is processed, which is the case for regular UI applications. When it's not the main queue or the object was passed to Kotlin on a thread other than main, the `objc_release` is called on a special GC thread as before.

How to opt out

In case you face issues, you can disable this behavior in your `gradle.properties` file with the following option:

```
kotlin.native.binary.objcDisposeOnMain=false
```

Don't hesitate to report such cases to our issue tracker.

No object initialization when accessing constant values in Kotlin/Native

Starting with Kotlin 1.9.0, the Kotlin/Native backend doesn't initialize objects when accessing `const val` fields:

```
object MyObject {
    init {
        println("side effect!")
    }

    const val y = 1
}

fun main() {
    println(MyObject.y) // No initialization at first
    val x = MyObject    // Initialization occurs
    println(x.y)
}
```

The behavior is now unified with Kotlin/JVM, where the implementation is consistent with Java and objects are never initialized in this case. You can also expect some performance improvements in your Kotlin/Native projects thanks to this change.

Ability to configure standalone mode for iOS simulator tests in Kotlin/Native

By default, when running iOS simulator tests for Kotlin/Native, the `--standalone` flag is used to avoid manual simulator booting and shutdown. In 1.9.0, you can now configure whether this flag is used in a Gradle task via the `standalone` property. By default, the `--standalone` flag is used so standalone mode is enabled.

Here is an example of how to disable standalone mode in your `build.gradle.kts` file:

```
tasks.withType<org.jetbrains.kotlin.gradle.targets.native.tasks.KotlinNativeSimulatorTest>
().configureEach {
    standalone.set(false)
}
```

If you disable standalone mode, you must boot the simulator manually. To boot your simulator from CLI, you can use the following command:

```
/usr/bin/xcrun simctl boot <DeviceId>
```

Library linkage in Kotlin/Native

Starting with Kotlin 1.9.0, the Kotlin/Native compiler treats linkage issues in Kotlin libraries the same way as Kotlin/JVM. You might face such issues if the author of one third-party Kotlin library makes an incompatible change in experimental APIs that another third-party Kotlin library consumes.

Now builds don't fail during compilation in case of linkage issues between third-party Kotlin libraries. Instead, you'll only encounter these errors in run time, exactly as on the JVM.

The Kotlin/Native compiler reports warnings every time it detects issues with library linkage. You can find such warnings in your compilation logs, for example:

```
No function found for symbol 'org.samples/MyRemovedClass.doSomething|3657632771909858561[0]'

Can not get instance of singleton 'MyEnumClass.REMOVED_ENTRY': No enum entry found for symbol
'org.samples/MyEnumClass.REMOVED_ENTRY|null[0]'

Function 'getMyRemovedClass' can not be called: Function uses unlinked class symbol
'org.samples/MyRemovedClass|null[0]'
```

You can further configure or even disable this behavior in your projects:

- If you don't want to see these warnings in your compilation logs, suppress them with the `-Xpartial-linkage-loglevel=INFO` compiler option.
- It's also possible to raise the severity of reported warnings to compilation errors with `-Xpartial-linkage-loglevel=ERROR`. In this case, the compilation fails and you'll see all the errors in the compilation log. Use this option to examine the linkage issues more closely.
- If you face unexpected problems with this feature, you can always opt out with the `-Xpartial-linkage=disable` compiler option. Don't hesitate to report such cases to our issue tracker.

```
// An example of passing compiler options via Gradle build file.
kotlin {
    macosX64("native") {
        binaries.executable()

        compilations.configureEach {
            compilerOptions.configure {
                // To suppress linkage warnings:
                freeCompilerArgs.add("-Xpartial-linkage-loglevel=INFO")

                // To raise linkage warnings to errors:
                freeCompilerArgs.add("-Xpartial-linkage-loglevel=ERROR")

                // To disable the feature completely:
                freeCompilerArgs.add("-Xpartial-linkage=disable")
            }
        }
    }
}
```

Compiler option for C interop implicit integer conversions

We have introduced a compiler option for C interop that allows you to use implicit integer conversions. After careful consideration, we've introduced this compiler option to prevent unintentional use as this feature still has room for improvement and our aim is to have an API of the highest quality.

In this code sample an implicit integer conversion allows `options = 0` even though `options` has unsigned type `UInt` and `0` is signed.

```
val today = NSDate()
val tomorrow = NSCalendar.currentCalendar.dateByAddingUnit(
    unit = NSCalendarUnitDay,
    value = 1,
    toDate = today,
    options = 0
)
```

To use implicit conversions with native interop libraries, use the `-XXLanguage:+ImplicitSignedToUnsignedIntegerConversion` compiler option.

You can configure this in your Gradle `build.gradle.kts` file:

```
tasks.withType<org.jetbrains.kotlin.gradle.tasks.KotlinNativeCompile>().configureEach {
    compilerOptions.freeCompilerArgs.addAll(
        "-XXLanguage:+ImplicitSignedToUnsignedIntegerConversion"
    )
}
```

Kotlin Multiplatform

Kotlin Multiplatform has received some notable updates in 1.9.0 designed to improve your developer experience:

- Changes to Android target support
- New Android source set layout enabled by default
- Preview of the Gradle configuration cache in multiplatform projects

Changes to Android target support

We continue our efforts to stabilize Kotlin Multiplatform. An essential step is to provide first-class support for the Android target. We're excited to announce that in the future, the Android team from Google will provide its own Gradle plugin to support Android in Kotlin Multiplatform.

To open the way for this new solution from Google, we're renaming the `android` block in the current Kotlin DSL in 1.9.0. Please change all the occurrences of the `android` block to `androidTarget` in your build scripts. This is a temporary change that is necessary to free the `android` name for the upcoming DSL from Google.

The Google plugin will be the preferred way of working with Android in multiplatform projects. When it's ready, we'll provide the necessary migration instructions so that you'll be able to use the short `android` name as before.

New Android source set layout enabled by default

Starting with Kotlin 1.9.0, the new Android source set layout is the default. It replaced the previous naming schema for directories, which was confusing in multiple ways. The new layout has a number of advantages:

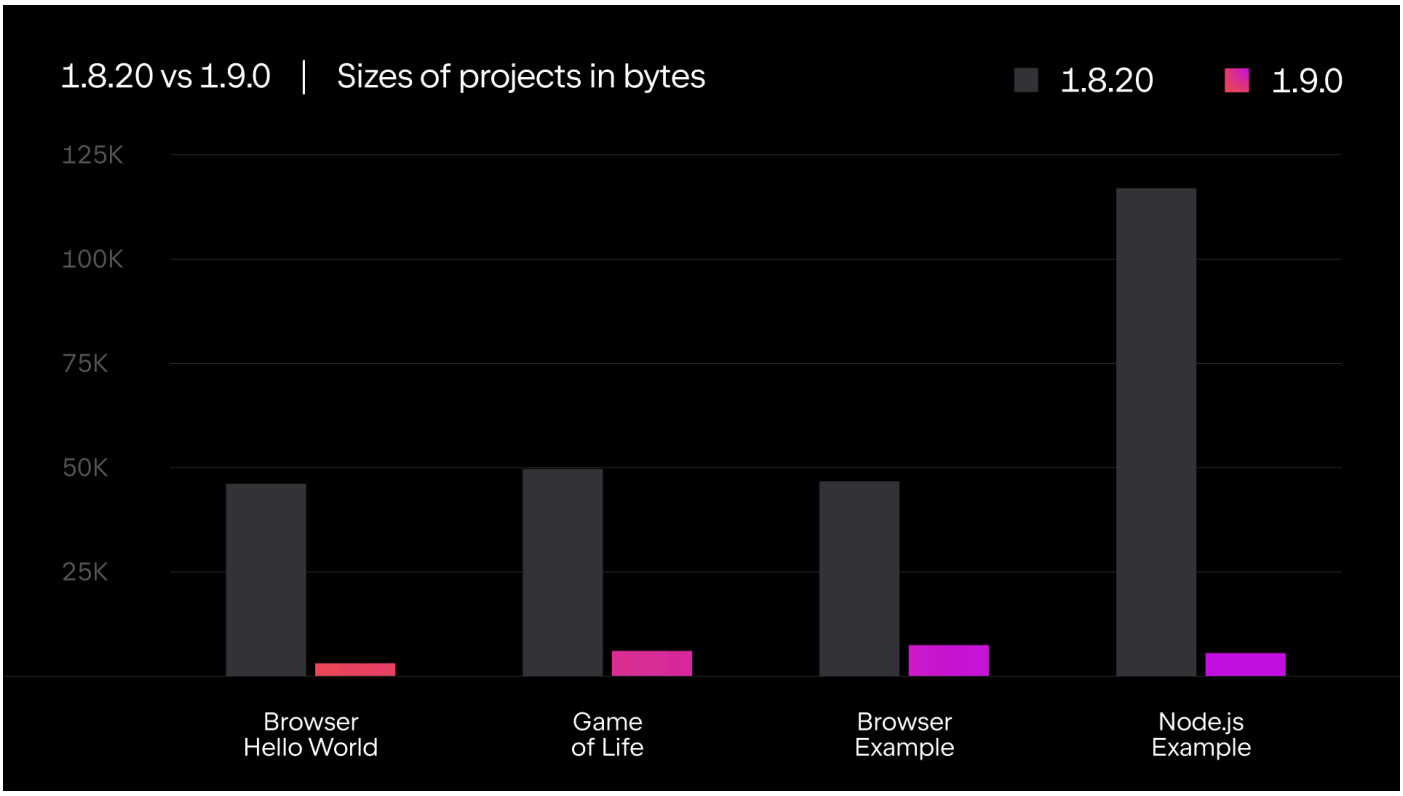
- Simplified type semantics – The new Android source layout provides clear and consistent naming conventions that help to distinguish between different types of source sets.
- Improved source directory layout – With the new layout, the `SourceDirectories` arrangement becomes more coherent, making it easier to organize code and locate source files.
- Clear naming schema for Gradle configurations – The schema is now more consistent and predictable in both `KotlinSourceSets` and `AndroidSourceSets`.

The new layout requires the Android Gradle plugin version 7.0 or later and is supported in Android Studio 2022.3 and later. See our migration guide to make the necessary changes in your `build.gradle(.kts)` file.

Preview of the Gradle configuration cache

Kotlin 1.9.0 comes with support for the Gradle configuration cache in multiplatform libraries. If you're a library author, you can already benefit from the improved build performance.

The Gradle configuration cache speeds up the build process by reusing the results of the configuration phase for subsequent builds. The feature has become Stable since Gradle 8.1. To enable it, follow the instructions in the Gradle documentation.



> The Kotlin Multiplatform plugin still doesn't support the Gradle configuration cache with Xcode integration tasks or the Kotlin CocoaPods Gradle plugin. We expect to add this feature in future Kotlin releases.

Kotlin/Wasm

The Kotlin team continues to experiment with the new Kotlin/Wasm target. This release introduces several performance and size-related optimizations, along with updates in JavaScript interop.

Size-related optimizations

Kotlin 1.9.0 introduces significant size improvements for WebAssembly (Wasm) projects. Comparing two "Hello World" projects, the code footprint for Wasm in Kotlin 1.9.0 is now over 10 times smaller than in Kotlin 1.8.20.

Kotlin/Wasm size-related optimizations

These size optimizations result in more efficient resource utilization and improved performance when targeting Wasm platforms with Kotlin code.

Updates in JavaScript interop

This Kotlin update introduces changes to the interoperability between Kotlin and JavaScript for Kotlin/Wasm. As Kotlin/Wasm is an Experimental feature, certain limitations apply to its interoperability.

Restriction of Dynamic types

Starting with version 1.9.0, Kotlin no longer supports the use of `Dynamic` types in Kotlin/Wasm. This is now deprecated in favor of the new universal `JsAny` type, which facilitates JavaScript interoperability.

For more details, see the Kotlin/Wasm interoperability with JavaScript documentation.

Restriction of non-external types

Kotlin/Wasm supports conversions for specific Kotlin static types when passing values to and from JavaScript. These supported types include:

- Primitives, such as signed numbers, `Boolean`, and `Char`.
- `String`.
- Function types.

Other types were passed without conversion as opaque references, leading to inconsistencies between JavaScript and Kotlin subtyping.

To address this, Kotlin restricts JavaScript interop to a well-supported set of types. Starting from Kotlin 1.9.0, only external, primitive, string, and function types are supported in Kotlin/Wasm JavaScript interop. Furthermore, a

separate explicit type called `JsReference` has been introduced to represent handles to Kotlin/Wasm objects that can be used in JavaScript interop.

For more details, refer to the Kotlin/Wasm interoperability with JavaScript documentation.

Kotlin/Wasm in Kotlin Playground

Kotlin Playground supports the Kotlin/Wasm target. You can write, run, and share your Kotlin code that targets the Kotlin/Wasm. Check it out!

> Using Kotlin/Wasm requires enabling experimental features in your browser.
>
> Learn more about how to enable these features.

```
import kotlin.time.*
import kotlin.time.measureTime

fun main() {
    println("Hello from Kotlin/Wasm!")
    computeAck(3, 10)
}

tailrec fun ack(m: Int, n: Int): Int = when {
    m == 0 -> n + 1
    n == 0 -> ack(m - 1, 1)
    else -> ack(m - 1, ack(m, n - 1))
}

fun computeAck(m: Int, n: Int) {
    var res = 0
    val t = measureTime {
        res = ack(m, n)
    }
    println()
    println("ack($m, $n) = ${res}")
    println("duration: ${t.inWholeNanoseconds / 1e6} ms")
}
```

Kotlin/JS

This release introduces updates for Kotlin/JS, including the removal of the old Kotlin/JS compiler, Kotlin/JS Gradle plugin deprecation and Experimental support for ES2015:

- Removal of the old Kotlin/JS compiler
- Deprecation of the Kotlin/JS Gradle plugin
- Deprecation of external enum
- Experimental support for ES2015 classes and modules
- Changed default destination of JS production distribution
- Extract org.w3c declarations from stdlib-js

> Starting from version 1.9.0, partial library linkage is also enabled for Kotlin/JS.

Removal of the old Kotlin/JS compiler

In Kotlin 1.8.0, we announced that the IR-based backend became Stable. Since then, not specifying the compiler has become an error, and using the old compiler leads to warnings.

In Kotlin 1.9.0, using the old backend results in an error. Please migrate to the IR compiler.

Deprecation of the Kotlin/JS Gradle plugin

Starting with Kotlin 1.9.0, the `kotlin-js` Gradle plugin is deprecated. We encourage you to use the `kotlin-multiplatform` Gradle plugin with the `js()` target instead.

The functionality of the Kotlin/JS Gradle plugin essentially duplicated the `kotlin-multiplatform` plugin and shared the same implementation under the hood. This overlap created confusion and increased maintenance load on the Kotlin team.

Refer to our Compatibility guide for Kotlin Multiplatform for migration instructions. If you find any issues that aren't covered in the guide, please report them to our issue tracker.

Deprecation of external enum

In Kotlin 1.9.0, the use of external enums will be deprecated due to issues with static enum members like `entries`, that can't exist outside Kotlin. We recommend using an external sealed class with object subclasses instead:

```
// Before
external enum class ExternalEnum { A, B }

// After
external sealed class ExternalEnum {
    object A: ExternalEnum
    object B: ExternalEnum
}
```

By switching to an external sealed class with object subclasses, you can achieve similar functionality to external enums while avoiding the problems associated with default methods.

Starting from Kotlin 1.9.0, the use of external enums will be marked as deprecated. We encourage you to update your code to utilize the suggested external sealed class implementation for compatibility and future maintenance.

Experimental support for ES2015 classes and modules

This release introduces Experimental support for ES2015 modules and generation of ES2015 classes:

- Modules offer a way to simplify your codebase and improve maintainability.
- Classes allow you to incorporate object-oriented programming (OOP) principles, resulting in cleaner and more intuitive code.

To enable these features, update your `build.gradle.kts` file accordingly:

```
// build.gradle.kts
kotlin {
    js(IR) {
        useEsModules() // Enables ES2015 modules
        browser()
    }
}

// Enables ES2015 classes generation
tasks.withType<KotlinJsCompile>().configureEach {
    kotlinOptions {
        useEsClasses = true
    }
}
```

Learn more about ES2015 (ECMAScript 2015, ES6) in the official documentation.

Changed default destination of JS production distribution

Prior to Kotlin 1.9.0, the distribution target directory was `build/distributions`. However, this is a common directory for Gradle archives. To resolve this issue, we've changed the default distribution target directory in Kotlin 1.9.0 to: `build/dist/<targetName>/<binaryName>`.

For example, `productionExecutable` was in `build/distributions`. In Kotlin 1.9.0, it's in `build/dist/js/productionExecutable`.

If you have a pipeline in place that uses the results of these builds, make sure to update the directory.

Extract org.w3c declarations from stdlib-js

Since Kotlin 1.9.0, the `stdlib-js` no longer includes `org.w3c` declarations. Instead, these declarations have been moved to a separate Gradle dependency. When you add the Kotlin Multiplatform Gradle plugin to your `build.gradle.kts` file, these declarations will be automatically included in your project, similar to the standard library.

There is no need for any manual action or migration. The necessary adjustments will be handled automatically.

Gradle

Kotlin 1.9.0 comes with new Gradle compiler options and a lot more:

- Removed classpath property
- New Gradle compiler options
- Project-level compiler options for Kotlin/JVM
- Compiler option for Kotlin/Native module name
- Separate compiler plugins for official Kotlin libraries
- Incremented minimum supported version
- kapt doesn't cause eager task creation
- Programmatic configuration of the JVM target validation mode

Removed classpath property

In Kotlin 1.7.0, we announced the start of a deprecation cycle for the `KotlinCompile` task's property: `classpath`. The deprecation level was raised to `ERROR` in Kotlin 1.8.0. In this release, we've finally removed the `classpath` property. All compile tasks should now use the `libraries` input for a list of libraries required for compilation.

New compiler options

The Kotlin Gradle plugin now provides new properties for opt-ins and the compiler's progressive mode.

- To opt in to new APIs, you can now use the `optIn` property and pass a list of strings like: `optIn.set(listOf(a, b, c))`.
- To enable progressive mode, use `progressiveMode.set(true)`.

Project-level compiler options for Kotlin/JVM

Starting with Kotlin 1.9.0, a new `compilerOptions` block is available inside the `kotlin` configuration block:

```
kotlin {
    compilerOptions {
        jvmTarget.set(JVM.Target_11)
    }
}
```

It makes configuring compiler options much easier. However, it is important to note some important details:

- This configuration only works on the project level.
- For the Android plugin, this block configures the same object as:

```
android {
    kotlinOptions {}
}
```

- The `android.kotlinOptions` and `kotlin.compilerOptions` configuration blocks override each other. The last (lowest) block in the build file always takes effect.
- If `moduleName` is configured on the project level, its value could be changed when passed to the compiler. It's not the case for the `main` compilation, but for other types, for example, test sources, the Kotlin Gradle plugin will add the `_test` suffix.
- The configuration inside the `tasks.withType<KotlinJvmCompile>().configureEach {}` (or `tasks.named<KotlinJvmCompile>("compileKotlin") { }`) overrides both `kotlin.compilerOptions` and `android.kotlinOptions`.

Compiler option for Kotlin/Native module name

The Kotlin/Native `module-name` compiler option is now easily available in the Kotlin Gradle plugin.

This option specifies a name for the compilation module and can also be used for adding a name prefix for declarations exported to Objective-C.

You can now set the module name directly in the `compilerOptions` block of your Gradle build files:

Kotlin

```kotlin
tasks.named<org.jetbrains.kotlin.gradle.tasks.KotlinNativeCompile>("compileKotlinLinuxX64") {
    compilerOptions {
        moduleName.set("my-module-name")
    }
}
```

Groovy

```groovy
tasks.named("compileKotlinLinuxX64", org.jetbrains.kotlin.gradle.tasks.KotlinNativeCompile.class) {
    compilerOptions {
        moduleName = "my-module-name"
    }
}
```

Separate compiler plugins for official Kotlin libraries

Kotlin 1.9.0 introduces separate compiler plugins for its official libraries. Previously, compiler plugins were embedded into their corresponding Gradle plugins. This could cause compatibility issues in case the compiler plugin was compiled against a Kotlin version higher than the Gradle build's Kotlin runtime version.

Now compiler plugins are added as separate dependencies, so you'll no longer face compatibility issues with older Gradle versions. Another major advantage of the new approach is that new compiler plugins can be used with other build systems like Bazel.

Here's the list of new compiler plugins we're now publishing to Maven Central:

- kotlin-atomicfu-compiler-plugin
- kotlin-allopen-compiler-plugin
- kotlin-lombok-compiler-plugin
- kotlin-noarg-compiler-plugin
- kotlin-sam-with-receiver-compiler-plugin
- kotlinx-serialization-compiler-plugin

Every plugin has its `-embeddable` counterpart, for example, `kotlin-allopen-compiler-plugin-embeddable` is designed for working with the `kotlin-compiler-embeddable` artifact, the default option for scripting artifacts.

Gradle adds these plugins as compiler arguments. You don't need to make any changes to your existing projects.

Incremented minimum supported version

Starting with Kotlin 1.9.0, the minimum supported Android Gradle plugin version is 4.2.2.

See the Kotlin Gradle plugin's compatibility with available Gradle versions in our documentation.

kapt doesn't cause eager task creation in Gradle

Prior to 1.9.0, the kapt compiler plugin caused eager task creation by requesting the configured instance of the Kotlin compilation task. This behavior has been fixed in Kotlin 1.9.0. If you use the default configuration for your `build.gradle.kts` file then your setup is not affected by this change.

If you use a custom configuration, your setup will be adversely affected. For example, if you have modified the `KotlinJvmCompile` task using Gradle's tasks API, you must similarly modify the `KaptGenerateStubs` task in your build script.

For example, if your script has the following configuration for the `KotlinJvmCompile` task:

```
tasks.named<KotlinJvmCompile>("compileKotlin") { // Your custom configuration }
```

In this case, you need to make sure that the same modification is included as part of the `KaptGenerateStubs` task:

```
tasks.named<KaptGenerateStubs>("kaptGenerateStubs") { // Your custom configuration }
```

For more information, see our YouTrack ticket.

Programmatic configuration of the JVM target validation mode

Before Kotlin 1.9.0, there was only one way to adjust the detection of JVM target incompatibility between Kotlin and Java. You had to set `kotlin.jvm.target.validation.mode=ERROR` in your `gradle.properties` for the whole project.

You can now also configure it on the task level in your `build.gradle.kts` file:

```
tasks.named<org.jetbrains.kotlin.gradle.tasks.KotlinJvmCompile>("compileKotlin") {
    jvmTargetValidationMode.set(org.jetbrains.kotlin.gradle.dsl.jvm.JvmTargetValidationMode.WARNING)
}
```

Standard library

Kotlin 1.9.0 has some great improvements for the standard library:

- The `..<` operator and time API are Stable.
- The Kotlin/Native standard library has been thoroughly reviewed and updated
- The `@Volatile` annotation can be used on more platforms
- There's a **common** function to get a regex capture group by name
- The `HexFormat` class has been introduced to format and parse hexadecimals

Stable ..< operator for open-ended ranges

The new `..<` operator for open-ended ranges that was introduced in Kotlin 1.7.20 and became Stable in 1.8.0. In 1.9.0, the standard library API for working with open-ended ranges is also Stable.

Our research shows that the new `..<` operator makes it easier to understand when an open-ended range is declared. If you use the `until` infix function, it's easy to make the mistake of assuming that the upper bound is included.

Here is an example using the `until` function:

```
fun main() {
    for (number in 2 until 10) {
        if (number % 2 == 0) {
            print("$number ")
        }
    }
    // 2 4 6 8
}
```

And here is an example using the new `..<` operator:

```
fun main() {
    for (number in 2..<10) {
        if (number % 2 == 0) {
            print("$number ")
        }
    }
    // 2 4 6 8
}
```

From IntelliJ IDEA version 2023.1.1, a new code inspection is available that highlights when you can use the `..<` operator.

For more information about what you can do with this operator, see What's new in Kotlin 1.7.20.

Stable time API

Since 1.3.50, we have previewed a new time measurement API. The duration part of the API became Stable in 1.6.0. In 1.9.0, the remaining time measurement API is Stable.

The old time API provided the `measureTimeMillis` and `measureNanoTime` functions, which aren't intuitive to use. Although it is clear that they both measure time in different units, it isn't clear that `measureTimeMillis` uses a wall clock to measure time, whereas `measureNanoTime` uses a monotonic time source. The new time API resolves this and other issues to make the API more user friendly.

With the new time API, you can easily:

- Measure the time taken to execute some code using a monotonic time source with your desired time unit.
- Mark a moment in time.
- Compare and find the difference between two moments in time.
- Check how much time has passed since a specific moment in time.
- Check whether the current time has passed a specific moment in time.

Measure code execution time

To measure the time taken to execute a block of code, use the `measureTime` inline function.

To measure the time taken to execute a block of code **and** return the result of the block of code, use the `measureTimedValue` inline function.

By default, both functions use a monotonic time source. However, if you want to use an elapsed real-time source, you can. For example, on Android the default time source `System.nanoTime()` only counts time while the device is active. It loses track of time when the device enters deep sleep. To keep track of time while the device is in deep sleep, you can create a time source that uses `SystemClock.elapsedRealtimeNanos()` instead:

```
object RealtimeMonotonicTimeSource : AbstractLongTimeSource(DurationUnit.NANOSECONDS) {
    override fun read(): Long = SystemClock.elapsedRealtimeNanos()
}
```

Mark and measure differences in time

To mark a specific moment in time, use the `TimeSource` interface and the `markNow()` function to create a `TimeMark`. To measure differences between `TimeMarks` from the same time source, use the subtraction operator (`-`):

```
import kotlin.time.*

fun main() {
    val timeSource = TimeSource.Monotonic
    val mark1 = timeSource.markNow()
    Thread.sleep(500) // Sleep 0.5 seconds.
    val mark2 = timeSource.markNow()

    repeat(4) { n ->
        val mark3 = timeSource.markNow()
        val elapsed1 = mark3 - mark1
        val elapsed2 = mark3 - mark2

        println("Measurement 1.${n + 1}: elapsed1=$elapsed1, elapsed2=$elapsed2, diff=${elapsed1 -
elapsed2}")
    }
    // It's also possible to compare time marks with each other.
    println(mark2 > mark1) // This is true, as mark2 was captured later than mark1.
}
```

To check if a deadline has passed or a timeout has been reached, use the `hasPassedNow()` and `hasNotPassedNow()` extension functions:

```
import kotlin.time.*
import kotlin.time.Duration.Companion.seconds

fun main() {
    val timeSource = TimeSource.Monotonic
    val mark1 = timeSource.markNow()
    val fiveSeconds: Duration = 5.seconds
    val mark2 = mark1 + fiveSeconds

    // It hasn't been 5 seconds yet
    println(mark2.hasPassedNow())
    // false

    // Wait six seconds
    Thread.sleep(6000)
    println(mark2.hasPassedNow())
    // true
}
```

The Kotlin/Native standard library's journey towards stabilization

As our standard library for Kotlin/Native continues to grow, we decided that it was time for a complete review to ensure that it meets our high standards. As part of this, we carefully reviewed **every** existing public signature. For each signature, we considered whether it:

- Has a unique purpose.
- Is consistent with other Kotlin APIs.
- Has similar behavior to its counterpart for the JVM.
- Is future-proof.

Based on these considerations, we made one of the following decisions:

- Made it Stable.
- Made it Experimental.
- Marked it as `private`.
- Modified its behavior.
- Moved it to a different location.
- Deprecated it.
- Marked it as obsolete.

If an existing signature has been:

- Moved to another package, then the signature still exists in the original package but it's now deprecated with deprecation level: `WARNING`. IntelliJ IDEA will automatically suggest replacements upon code inspection.
- Deprecated, then it's been deprecated with deprecation level: `WARNING`.
- Marked as obsolete, then you can keep using it, but it will be replaced in future.

We won't list all of the results of the review here, but here are some of the highlights:

- We stabilized the Atomics API.
- We made `kotlinx.cinterop` Experimental and now require different opt-ins for the package to be used. For more information, see Explicit C-interoperability stability guarantees.
- We marked the `Worker` class and its related APIs as obsolete.
- We marked the `BitSet` class as obsolete.
- We marked all `public` APIs in the `kotlin.native.internal` package as `private` or moved them to other packages.

Explicit C-interoperability stability guarantees

To maintain the high quality of our API, we decided to make `kotlinx.cinterop` Experimental. Although `kotlinx.cinterop` has been thoroughly tried and tested, there is still room for improvement before we are satisfied enough to make it Stable. We recommend that you use this API for interoperability but that you try to confine its use to specific areas in your projects. This will make your migration easier once we begin evolving this API to make it Stable.

If you want to use C-like foreign APIs such as pointers, you must opt in with `@OptIn(ExperimentalForeignApi)`, otherwise your code won't compile.

To use the remainder of `kotlinx.cinterop`, which covers Objective-C/Swift interoperability, you must opt in with `@OptIn(BetaInteropApi)`. If you try to use this API without the opt-in, your code will compile but the compiler will raise warnings that provide a clear explanation of what behavior you can expect.

For more information about these annotations, see our source code for `Annotations.kt`.

For more information on **all** of the changes as part of this review, see our YouTrack ticket.

We'd appreciate any feedback you might have! You can provide your feedback directly by commenting on the ticket.

Stable @Volatile annotation

If you annotate a `var` property with `@Volatile`, then the backing field is marked so that any reads or writes to this field are atomic, and writes are always made visible to other threads.

Prior to 1.8.20, the `kotlin.jvm.Volatile` annotation was available in the common standard library. However, this annotation was only effective on the JVM. If you used it on other platforms, it was ignored, which led to errors.

In 1.8.20, we introduced an experimental common annotation, `kotlin.concurrent.Volatile`, which you could preview in both the JVM and Kotlin/Native.

In 1.9.0, `kotlin.concurrent.Volatile` is Stable. If you use `kotlin.jvm.Volatile` in your multiplatform projects, we recommend that you migrate to `kotlin.concurrent.Volatile`.

New common function to get regex capture group by name

Prior to 1.9.0, every platform had its own extension to get a regular expression capture group by its name from a regular expression match. However there was no common function. It wasn't possible to have a common function prior to Kotlin 1.8.0, because the standard library still supported JVM targets 1.6 and 1.7.

As of Kotlin 1.8.0, the standard library is compiled with JVM target 1.8. So in 1.9.0, there is now a **common** `groups` function that you can use to retrieve a group's contents by its name for a regular expression match. This is useful when you want to access the results of regular expression matches belonging to a particular capture group.

Here is an example with a regular expression containing three capture groups: `city`, `state`, and `areaCode`. You can use these group names to access the matched values:

```
fun main() {
    val regex = """\b(?<city>[A-Za-z\s]+),\s(?<state>[A-Z]{2}):\s(?<areaCode>[0-9]{3})\b""".toRegex()
    val input = "Coordinates: Austin, TX: 123"

    val match = regex.find(input)!!
    println(match.groups["city"]?.value)
    // Austin
    println(match.groups["state"]?.value)
    // TX
    println(match.groups["areaCode"]?.value)
    // 123
}
```

New path utility to create parent directories

In 1.9.0 there is a new `createParentDirectories()` extension function that you can use to create a new file with all the necessary parent directories. When you provide a file path to `createParentDirectories()` it checks whether the parent directories already exist. If they do, it does nothing. However, if they do not, it creates them for you.

`createParentDirectories()` is particularly useful when you are copying files. For example, you can use it in combination with the `copyToRecursively()` function:

```
sourcePath.copyToRecursively(
   destinationPath.createParentDirectories(),
   followLinks = false
)
```

New HexFormat class to format and parse hexadecimals

> The new `HexFormat` class and its related extension functions are Experimental, and to use them, you can opt in with `@OptIn(ExperimentalStdlibApi::class)` or the compiler argument `-opt-in=kotlin.ExperimentalStdlibApi`.

In 1.9.0, the `HexFormat` class and its related extension functions are provided as an Experimental feature that allows you to convert between numerical values and hexadecimal strings. Specifically, you can use the extension functions to convert between hexadecimal strings and `ByteArrays` or other numeric types (`Int`, `Short`, `Long`).

For example:

```
println(93.toHexString()) // "0000005d"
```

The `HexFormat` class includes formatting options that you can configure with the `HexFormat{}` builder.

If you are working with `ByteArrays` you have the following options, which are configurable by properties:

Option	Description
`upperCase`	Whether hexadecimal digits are upper or lower case. By default, lower case is assumed. `upperCase = false`.
`bytes.bytesPerLine`	The maximum number of bytes per line.
`bytes.bytesPerGroup`	The maximum number of bytes per group.
`bytes.bytesSeparator`	The separator between bytes. Nothing by default.
`bytes.bytesPrefix`	The string that immediately precedes a two-digit hexadecimal representation of each byte, nothing by default.
`bytes.bytesSuffix`	The string that immediately succeeds a two-digit hexadecimal representation of each byte, nothing by default.

For example:

```
val macAddress = "001b638445e6".hexToByteArray()

// Use HexFormat{} builder to separate the hexadecimal string by colons
println(macAddress.toHexString(HexFormat { bytes.byteSeparator = ":" }))
// "00:1b:63:84:45:e6"

// Use HexFormat{} builder to:
// * Make the hexadecimal string uppercase
// * Group the bytes in pairs
// * Separate by periods
val threeGroupFormat = HexFormat { upperCase = true; bytes.bytesPerGroup = 2; bytes.groupSeparator =
"." }

println(macAddress.toHexString(threeGroupFormat))
// "001B.6384.45E6"
```

If you are working with numeric types, you have the following options, which are configurable by properties:

Option	Description
`number.prefix`	The prefix of a hexadecimal string, nothing by default.
`number.suffix`	The suffix of a hexadecimal string, nothing by default.
`number.removeLeadingZeros`	Whether to remove leading zeros in a hexadecimal string. By default, no leading zeros are removed. `number.removeLeadingZeros = false`

For example:

```
// Use HexFormat{} builder to parse a hexadecimal that has prefix: "0x".
println("0x3a".hexToInt(HexFormat { number.prefix = "0x" })) // "58"
```

Documentation updates

The Kotlin documentation has received some notable changes:

- The tour of Kotlin – Learn the fundamentals of the Kotlin programming language with chapters including both theory and practice.
- Android source set layout – Learn about the new Android source set layout.
- Compatibility guide for Kotlin Multiplatform – Learn about the incompatible changes you might encounter while developing projects with Kotlin Multiplatform.
- Kotlin Wasm – Learn about Kotlin/Wasm and how you can use it in your Kotlin Multiplatform projects.

Install Kotlin 1.9.0

Check the IDE version

IntelliJ IDEA 2022.3.3 and 2023.1.1 automatically suggest updating the Kotlin plugin to version 1.9.0. IntelliJ IDEA 2023.2 will include the Kotlin 1.9.0 plugin.

Android Studio Giraffe (223) and Hedgehog (231) will support Kotlin 1.9.0 in their upcoming releases.

The new command-line compiler is available for download on the GitHub release page.

Configure Gradle settings

To download Kotlin artifacts and dependencies, update your `settings.gradle(.kts)` file to use the Maven Central repository:

```
pluginManagement {
    repositories {
        mavenCentral()
        gradlePluginPortal()
    }
}
```

If the repository is not specified, Gradle uses the sunset JCenter repository, which could lead to issues with Kotlin artifacts.

Compatibility guide for Kotlin 1.9.0

Kotlin 1.9.0 is a feature release and can, therefore, bring changes that are incompatible with your code written for earlier versions of the language. Find the detailed list of these changes in the Compatibility guide for Kotlin 1.9.0.

Compatibility guide for Kotlin 1.9.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.8 to Kotlin 1.9.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Remove language version 1.3

Issue: KT-61111

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 introduces language version 1.9 and removes support for language version 1.3.

Deprecation cycle:

- 1.6.0: report a warning
- 1.9.0: raise the warning to an error

Prohibit super constructor call when the super interface type is a function literal

Issue: KT-46344

Component: Core language

Incompatible change type: source

Short summary: If an interface inherits from a function literal type, Kotlin 1.9 prohibits super constructor calls because no such constructor exists.

Deprecation cycle:

- 1.7.0: report a warning (or an error in progressive mode)
- 1.9.0: raise the warning to an error

Prohibit cycles in annotation parameter types

Issue: KT-47932

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 prohibits the type of an annotation being used as one of its parameter types, either directly or indirectly. This prevents cycles from being created. However, you are allowed to have parameter types that are an `Array` or a `vararg` of the annotation type.

Deprecation cycle:

- 1.7.0: report a warning (or an error in progressive mode) on cycles in types of annotation parameters
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitCyclesInAnnotations` can be used to temporarily revert to pre-1.9 behavior

Prohibit use of @ExtensionFunctionType annotation on function types with no parameters

Issue: KT-43527

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 prohibits using the `@ExtensionFunctionType` annotation on function types with no parameters, or on types that aren't function types.

Deprecation cycle:

- 1.7.0: report a warning for annotations on types that aren't function types, report an error for annotations on types that **are** function types
- 1.9.0: raise the warning for function types to an error

Prohibit Java field type mismatch on assignment

Issue: KT-48994

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.9 reports a compiler error if it detects that the type of a value assigned to a Java field doesn't match the Java field's projected type.

Deprecation cycle:

- 1.6.0: report a warning (or an error in the progressive mode) when a projected Java field type doesn't match the assigned value type
- 1.9.0: raise the warning to an error, `-XXLanguage:-RefineTypeCheckingOnAssignmentsToJavaFields` can be used to temporarily revert to pre-1.9 behavior

No source code excerpts in platform-type nullability assertion exceptions

Issue: KT-57570

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: In Kotlin 1.9, exception messages for expression null checks do not include source code excerpts. Instead, the name of the method or field is displayed. If the expression is not a method or field, there is no additional information provided in the message.

Deprecation cycle:

- < 1.9.0: exception messages generated by expression null checks contain source code excerpts
- 1.9.0: exception messages generated by expression null checks contain method or field names only, `-XXLanguage:-NoSourceCodeInNotNullAssertionExceptions` can be used to temporarily revert to pre-1.9 behavior

Prohibit the delegation of super calls to an abstract superclass member

Issues: KT-45508, KT-49017, KT-38078

Component: Core language

Incompatible change type: source

Short summary: Kotlin will report a compile error when an explicit or implicit super call is delegated to an *abstract* member of the superclass, even if there's a default implementation in a super interface.

Deprecation cycle:

- 1.5.20: introduce a warning when non-abstract classes that do not override all abstract members are used
- 1.7.0: report a warning if a super call, in fact, accesses an abstract member from a superclass
- 1.7.0: report an error in all affected cases if the `-Xjvm-default=all` or `-Xjvm-default=all-compatibility` compatibility modes are enabled; report an error in the progressive mode
- 1.8.0: report an error in cases of declaring a concrete class with a non-overridden abstract method from the superclass, and super calls of `Any` methods are overridden as abstract in the superclass
- 1.9.0: report an error in all affected cases, including explicit super calls to an abstract method from the super class

Deprecate confusing grammar in when-with-subject

Issue: KT-48385

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 deprecated several confusing grammar constructs in `when` condition expressions.

Deprecation cycle:

- 1.6.20: introduce a deprecation warning on the affected expressions
- 1.8.0: raise this warning to an error, `-XXLanguage:-ProhibitConfusingSyntaxInWhenBranches` can be used to temporarily revert to the pre-1.8 behavior
- >= 2.1: repurpose some deprecated constructs for new language features

Prevent implicit coercions between different numeric types

Issue: KT-48645

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin will avoid converting numeric values automatically to a primitive numeric type where only a downcast to that type is needed semantically.

Deprecation cycle:

- < 1.5.30: the old behavior in all affected cases
- 1.5.30: fix the downcast behavior in generated property delegate accessors, `-Xuse-old-backend` can be used to temporarily revert to the pre-1.5.30 fix behavior
- >= 2.0: fix the downcast behavior in other affected cases

Prohibit upper bound violation in a generic type alias usage (a type parameter used in a generic type argument of a type argument of the aliased type)

Issue: KT-54066

Component: Core language

Incompatible change type: source

Short summary: Kotlin will prohibit using a type alias with type arguments that violate the upper bound restrictions of the corresponding type parameters of the aliased type in case when the typealias type parameter is used as a generic type argument of a type argument of the aliased type, for example, `typealias Alias<T> = Base<List<T>>`.

Deprecation cycle:

- 1.8.0: report a warning when a generic typealias usage has type arguments violating upper bound constraints of the corresponding type parameters of the aliased type
- 2.0.0: raise the warning to an error

Keep nullability when approximating local types in public signatures

Issue: KT-53982

Component: Core language

Incompatible change type: source, binary

Short summary: when a local or anonymous type is returned from an expression-body function without an explicitly specified return type, Kotlin compiler infers (or approximates) the return type using the known supertype of that type. During this, the compiler can infer a non-nullable type where the null value could in fact be returned.

Deprecation cycle:

- 1.8.0: approximate flexible types by flexible supertypes
- 1.8.0: report a warning when a declaration is inferred to have a non-nullable type that should be nullable, prompting users to specify the type explicitly
- 2.0.0: approximate nullable types by nullable supertypes, `-XXLanguage:-KeepNullabilityWhenApproximatingLocalType` can be used to temporarily revert to the pre-2.0 behavior

Do not propagate deprecation through overrides

Issue: KT-47902

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will no longer propagate deprecation from a deprecated member in the superclass to its overriding member in the subclass, thus providing an explicit mechanism for deprecating a member of the superclass while leaving it non-deprecated in the subclass.

Deprecation cycle:

- 1.6.20: reporting a warning with the message of the future behavior change and a prompt to either suppress this warning or explicitly write a `@Deprecated` annotation on an override of a deprecated member
- 1.9.0: stop propagating deprecation status to the overridden members. This change also takes effect immediately in the progressive mode

Prohibit using collection literals in annotation classes anywhere except their parameters declaration

Issue: KT-39041

Component: Core language

Incompatible change type: source

Short summary: Kotlin allows using collection literals in a restricted way - for passing arrays to parameters of annotation classes or specifying default values for these parameters. However besides that, Kotlin allowed using collections literals anywhere else inside an annotation class, for example, in its nested object. Kotlin 1.9 will prohibit using collection literals in annotation classes anywhere except their parameters' default values.

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) on array literals in nested objects in annotation classes
- 1.9.0: raise the warning to an error

Prohibit forward referencing of parameters in default value expressions

Issue: KT-25694

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit forward referencing of parameters in default value expressions of other parameters. This ensures that by the time the parameter is accessed in a default value expression, it would already have a value either passed to the function or initialized by its own default value expression.

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) when a parameter with default value is references in default value of another parameter that comes before it
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitIllegalValueParameterUsageInDefaultArguments` can be used to temporarily revert to the pre-1.9 behavior

Prohibit extension calls on inline functional parameters

Issue: KT-52502

Component: Core language

Incompatible change type: source

Short summary: while Kotlin allowed passing an inline functional parameter to another inline function as a receiver, it always resulted in compiler exceptions when compiling such code. Kotlin 1.9 will prohibit this, thus reporting an error instead of crashing the compiler.

Deprecation cycle:

- 1.7.20: report a warning (or an error in the progressive mode) for inline extension calls on inline functional parameters
- 1.9.0: raise the warning to an error

Prohibit calls to infix functions named suspend with an anonymous function argument

Issue: KT-49264

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will no longer allow calling infix functions named `suspend` that have a single argument of a functional type passed as an anonymous function literal.

Deprecation cycle:

- 1.7.20: report a warning on suspend infix calls with an anonymous function literal
- 1.9.0: raise the warning to an error, `-XXLanguage:-ModifierNonBuiltinSuspendFunError` can be used to temporarily revert to the pre-1.9 behavior
- TODO: Change how the `suspend fun` token sequence is interpreted by the parser

Prohibit using captured type parameters in inner classes against their variance

Issue: KT-50947

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit using type parameters of an outer class having `in` or `out` variance in an inner class of that class in positions violating that type parameters' declared variance.

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) when an outer class' type parameter usage position violates the variance rules of that parameter
- 1.9.0: raise the warning to an error, `-XXLanguage:-ReportTypeVarianceConflictOnQualifierArguments` can be used to temporarily revert to the pre-1.9 behavior

Prohibit recursive call of a function without explicit return type in compound assignment operators

Issue: KT-48546

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit calling a function without explicitly specified return type in an argument of a compound assignment operator inside that function's body, as it currently does in other expressions inside the body of that function.

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) when a function without explicitly specified return type is called recursively in that function's body in a compound assignment operator argument
- 1.9.0: raise the warning to an error

Prohibit unsound calls with expected @NotNull T and given Kotlin generic parameter with nullable bound

Issue: KT-36770

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit method calls where a value of a potentially nullable generic type is passed for a `@NotNull`-annotated parameter of a Java method.

Deprecation cycle:

- 1.5.20: report a warning when an unconstrained generic type parameter is passed where a non-nullable type is expected
- 1.9.0: report a type mismatch error instead of the warning above, `-XXLanguage:-ProhibitUsingNullableTypeParameterAgainstNotNullAnnotated` can be used to temporarily revert to the pre-1.8 behavior

Prohibit access to members of a companion of an enum class from entry initializers of this enum

Issue: KT-49110

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit all kinds of access to the companion object of an enum from an enum entry initializer.

Deprecation cycle:

- 1.6.20: report a warning (or an error in the progressive mode) on such companion member access
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitAccessToEnumCompanionMembersInEnumConstructorCall` can be used to temporarily revert to the pre-1.8 behavior

Deprecate and remove Enum.declaringClass synthetic property

Issue: KT-49653

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin allowed using the synthetic property `declaringClass` on `Enum` values produced from the method `getDeclaringClass()` of the underlying Java class `java.lang.Enum` even though this method is not available for Kotlin `Enum` type. Kotlin 1.9 will prohibit using this property, proposing to migrate to the extension property `declaringJavaClass` instead.

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) on `declaringClass` property usages, propose the migration to `declaringJavaClass` extension
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitEnumDeclaringClass` can be used to temporarily revert to the pre-1.9 behavior
- 2.0.0: remove `declaringClass` synthetic property

Deprecate enable and compatibility modes of the compiler option -Xjvm-default

Issues: KT-46329, KT-54746

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.9 prohibits using the `enable` and `compatibility` modes of the `-Xjvm-default` compiler option.

Deprecation cycle:

- 1.6.20: introduce a warning on the `enable` and `compatibility` modes of the `-Xjvm-default` compiler option
- 1.9.0: raise this warning to an error

Prohibit implicit inferring a type variable into an upper bound in the builder inference context

Issue: KT-47986

Component: Core language

Incompatible change type: source

Short summary: Kotlin 2.0 will prohibit inferring a type variable into the corresponding type parameter's upper bound in the absence of any use-site type information in the scope of builder inference lambda functions, the same way as it does currently in other contexts.

Deprecation cycle:

- 1.7.20: report a warning (or an error in the progressive mode) when a type parameter is inferred into declared upper bounds in the absence of use-site type information
- 2.0.0: raise the warning to an error

Standard library

Warn about potential overload resolution change when Range/Progression starts implementing Collection

Issue: KT-49276

Component: Core language / kotlin-stdlib

Incompatible change type: source

Short summary: it is planned to implement the `Collection` interface in the standard progressions and concrete ranges inherited from them in Kotlin 1.9. This could make a different overload selected in the overload resolution if there are two overloads of some method, one accepting an element and another accepting a collection. Kotlin will make this situation visible by reporting a warning or an error when such overloaded method is called with a range or progression argument.

Deprecation cycle:

- 1.6.20: report a warning when an overloaded method is called with the standard progression or its range inheritor as an argument if implementing the `Collection` interface by this progression/range leads to another overload being selected in this call in future
- 1.8.0: raise this warning to an error
- 2.1.0: stop reporting the error, implement `Collection` interface in progressions thus changing the overload resolution result in the affected cases

Migrate declarations from kotlin.dom and kotlin.browser packages to kotlinx.*

Issue: KT-39330

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: declarations from the `kotlin.dom` and `kotlin.browser` packages are moved to the corresponding `kotlinx.*` packages to prepare for extracting them from stdlib.

Deprecation cycle:

- 1.4.0: introduce the replacement API in `kotlinx.dom` and `kotlinx.browser` packages
- 1.4.0: deprecate the API in `kotlin.dom` and `kotlin.browser` packages and propose the new API above as a replacement
- 1.6.0: raise the deprecation level to an error
- 1.8.20: remove the deprecated functions from stdlib for JS-IR target
- >= 2.0: move the API in kotlinx.* packages to a separate library

Deprecate some JS-only API

Issue: KT-48587

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: a number of JS-only functions in stdlib are deprecated for removal. They include: `String.concat(String)`, `String.match(regex: String)`, `String.matches(regex: String)`, and the `sort` functions on arrays taking a comparison function, for example, `Array<out T>.sort(comparison: (a: T, b: T) -> Int)`.

Deprecation cycle:

- 1.6.0: deprecate the affected functions with a warning
- 1.9.0: raise the deprecation level to an error
- >=2.0: remove the deprecated functions from the public API

Tools

Remove enableEndorsedLibs flag from Gradle setup

Issue: KT-54098

Component: Gradle

Incompatible change type: source

Short summary: the `enableEndorsedLibs` flag is no longer supported in Gradle setup.

Deprecation cycle:

- < 1.9.0: `enableEndorsedLibs` flag is supported in Gradle setup
- 1.9.0: `enableEndorsedLibs` flag is **not** supported in Gradle setup

Remove Gradle conventions

Issue: KT-52976

Component: Gradle

Incompatible change type: source

Short summary: Gradle conventions were deprecated in Gradle 7.1 and have been removed in Gradle 8.

Deprecation cycle:

- 1.7.20: Gradle conventions deprecated
- 1.9.0: Gradle conventions removed

Remove classpath property of KotlinCompile task

Issue: KT-53748

Component: Gradle

Incompatible change type: source

Short summary: the `classpath` property of the `KotlinCompile` task is removed.

Deprecation cycle:

- 1.7.0: the `classpath` property is deprecated
- 1.8.0: raise the deprecation level to an error
- 1.9.0: remove the deprecated functions from the public API

Deprecate kotlin.internal.single.build.metrics.file property

Issue: KT-53357

Component: Gradle

Incompatible change type: source

Short summary: deprecate the `kotlin.internal.single.build.metrics.file` property used to define a single file for build reports. Use the property `kotlin.build.report.single_file` instead with `kotlin.build.report.output=single_file`.

Deprecation cycle:

- 1.8.0: raise the deprecation level to a warning
- >= 1.9: delete the property

What's new in Kotlin 1.8.20

Released: 25 April 2023

The Kotlin 1.8.20 release is out and here are some of its biggest highlights:

- New Kotlin K2 compiler updates
- New experimental Kotlin/Wasm target
- New JVM incremental compilation by default in Gradle
- Update for Kotlin/Native targets
- Preview of Gradle composite builds in Kotlin Multiplatform
- Improved output for Gradle errors in Xcode
- Experimental support for the AutoCloseable interface in the standard library
- Experimental support for Base64 encoding in the standard library

You can also find a short overview of the changes in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugins that support 1.8.20 are available for:

IDE	Supported versions
IntelliJ IDEA	2022.2.x, 2022.3.x, 2023.1.x

IDE	Supported versions
Android Studio	Flamingo (222)

To download Kotlin artifacts and dependencies properly, configure Gradle settings to use the Maven Central repository.

New Kotlin K2 compiler updates

The Kotlin team continues to stabilize the K2 compiler. As mentioned in the Kotlin 1.7.0 announcement, it's still in **Alpha**. This release introduces further improvements on the road to K2 Beta.

Starting with this 1.8.20 release, the Kotlin K2 compiler:

- Has a preview version of the serialization plugin.
- Provides Alpha support for the JS IR compiler.
- Introduces the future release of the new language version, Kotlin 2.0.

Learn more about the new compiler and its benefits in the following videos:

- What Everyone Must Know About The NEW Kotlin K2 Compiler
- The New Kotlin K2 Compiler: Expert Review

How to enable the Kotlin K2 compiler

To enable and test the Kotlin K2 compiler, use the new language version with the following compiler option:

```
-language-version 2.0
```

You can specify it in your `build.gradle(.kts)` file:

```
kotlin {
   sourceSets.all {
       languageSettings {
           languageVersion = "2.0"
       }
   }
}
```

The previous `-Xuse-k2` compiler option has been deprecated.

The Alpha version of the new K2 compiler only works with JVM and JS IR projects. It doesn't support Kotlin/Native or any of the multiplatform projects yet.

Leave your feedback on the new K2 compiler

We would appreciate any feedback you may have!

- Provide your feedback directly to K2 developers on Kotlin Slack – get an invite and join the #k2-early-adopters channel.

- Report any problems you faced with the new K2 compiler on our issue tracker.
- Enable the **Send usage statistics** option to allow JetBrains to collect anonymous data about K2 usage.

Language

As Kotlin continues to evolve, we're introducing preview versions for new language features in 1.8.20:

- A modern and performant replacement of the Enum class values function
- Data objects for symmetry with data classes
- Lifting restrictions on secondary constructors with bodies in inline classes

A modern and performant replacement of the Enum class values function

This feature is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Enum classes have a synthetic `values()` function, which returns an array of defined enum constants. However, using an array can lead to hidden performance issues in Kotlin and Java. In addition, most of the APIs use collections, which require eventual conversion. To fix these problems, we've introduced the `entries` property for Enum classes, which should be used instead of the `values()` function. When called, the `entries` property returns a pre-allocated immutable list of defined enum constants.

The `values()` function is still supported, but we recommend that you use the `entries` property instead.

```
enum class Color(val colorName: String, val rgb: String) {
    RED("Red", "#FF0000"),
    ORANGE("Orange", "#FF7F00"),
    YELLOW("Yellow", "#FFFF00")
}

@OptIn(ExperimentalStdlibApi::class)
fun findByRgb(rgb: String): Color? = Color.entries.find { it.rgb == rgb }
```

How to enable the entries property

To try this feature out, opt in with `@OptIn(ExperimentalStdlibApi)` and enable the `-language-version 1.9` compiler option. In a Gradle project, you can do so by adding the following to your `build.gradle(.kts)` file:

Kotlin

```
tasks
    .withType<org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask<*>>()
    .configureEach {
        compilerOptions
            .languageVersion
            .set(
                org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
            )
    }
```

Groovy

```
tasks
    .withType(org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class)
    .configureEach {
        compilerOptions.languageVersion =
            org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
    }
```

Starting with IntelliJ IDEA 2023.1, if you have opted in to this feature, the appropriate IDE inspection will notify you about converting from `values()` to `entries` and offer a quick-fix.

For more information on the proposal, see the KEEP note.

Preview of data objects for symmetry with data classes

Data objects allow you to declare objects with singleton semantics and a clean `toString()` representation. In this snippet, you can see how adding the `data` keyword to an object declaration improves the readability of its `toString()` output:

```
package org.example
object MyObject
data object MyDataObject

fun main() {
    println(MyObject) // org.example.MyObject@1f32e575
    println(MyDataObject) // MyDataObject
}
```

Especially for `sealed` hierarchies (like a `sealed class` or `sealed interface` hierarchy), `data objects` are an excellent fit because they can be used conveniently alongside `data class` declarations. In this snippet, declaring `EndOfFile` as a `data object` instead of a plain `object` means that it will get a pretty `toString` without the need to override it manually. This maintains symmetry with the accompanying data class definitions.

```
sealed interface ReadResult
data class Number(val number: Int) : ReadResult
data class Text(val text: String) : ReadResult
data object EndOfFile : ReadResult

fun main() {
    println(Number(7)) // Number(number=7)
    println(EndOfFile) // EndOfFile
}
```

Semantics of data objects

Since their first preview version in Kotlin 1.7.20, the semantics of data objects have been refined. The compiler now automatically generates a number of convenience functions for them:

toString

The `toString()` function of a data object returns the simple name of the object:

```
data object MyDataObject {
    val x: Int = 3
}

fun main() {
    println(MyDataObject) // MyDataObject
}
```

equals and hashCode

The `equals()` function for a `data object` ensures that all objects that have the type of your `data object` are considered equal. In most cases, you will only have a single instance of your data object at runtime (after all, a `data object` declares a singleton). However, in the edge case where another object of the same type is generated at runtime (for example, via platform reflection through `java.lang.reflect`, or by using a JVM serialization library that uses this API under the hood), this ensures that the objects are treated as equal.

Make sure to only compare `data objects` structurally (using the `==` operator) and never by reference (the `===` operator). This helps avoid pitfalls when more than one instance of a data object exists at runtime. The following snippet illustrates this specific edge case:

```
import java.lang.reflect.Constructor

data object MySingleton

fun main() {
    val evilTwin = createInstanceViaReflection()

    println(MySingleton) // MySingleton
    println(evilTwin) // MySingleton

    // Even when a library forcefully creates a second instance of MySingleton, its `equals` method
returns true:
    println(MySingleton == evilTwin) // true

    // Do not compare data objects via ===.
    println(MySingleton === evilTwin) // false
}

fun createInstanceViaReflection(): MySingleton {
    // Kotlin reflection does not permit the instantiation of data objects.
    // This creates a new MySingleton instance "by force" (i.e., Java platform reflection)
    // Don't do this yourself!
    return (MySingleton.javaClass.declaredConstructors[0].apply { isAccessible = true } as
Constructor<MySingleton>).newInstance()
}
```

The behavior of the generated `hashCode()` function is consistent with that of the `equals()` function, so that all runtime instances of a `data object` have the same hash code.

No copy and componentN functions for data objects

While `data object` and `data class` declarations are often used together and have some similarities, there are some functions that are not generated for a `data object`:

Because a `data object` declaration is intended to be used as a singleton object, no `copy()` function is generated. The singleton pattern restricts the instantiation of a class to a single instance, and allowing copies of the instance to be created would violate that restriction.

Also, unlike a `data class`, a `data object` does not have any data properties. Since attempting to destructure such an object would not make sense, no `componentN()` functions are generated.

We would appreciate your feedback on this feature in YouTrack.

How to enable the data objects preview

To try this feature out, enable the `-language-version 1.9` compiler option. In a Gradle project, you can do so by adding the following to your `build.gradle(.kts)` file:

Kotlin

```
tasks
    .withType<org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask<*>>()
    .configureEach {
        compilerOptions
            .languageVersion
            .set(
                org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
            )
    }
```

Groovy

```
tasks
    .withType(org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class)
    .configureEach {
        compilerOptions.languageVersion =
            org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
    }
```

Preview of lifting restriction on secondary constructors with bodies in inline classes

This feature is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.8.20 lifts restrictions on the use of secondary constructors with bodies in inline classes.

Inline classes used to allow only a public primary constructor without `init` blocks or secondary constructors to have clear initialization semantics. As a result, it was impossible to encapsulate underlying values or create an inline class that would represent some constrained values.

These issues were fixed when Kotlin 1.4.30 lifted restrictions on `init` blocks. Now we're taking it a step further and allowing secondary constructors with bodies in preview mode:

```
@JvmInline
value class Person(private val fullName: String) {
    // Allowed since Kotlin 1.4.30:
    init {
        check(fullName.isNotBlank()) {
            "Full name shouldn't be empty"
        }
    }

    // Preview available since Kotlin 1.8.20:
    constructor(name: String, lastName: String) : this("$name $lastName") {
        check(lastName.isNotBlank()) {
            "Last name shouldn't be empty"
        }
    }
}
```

How to enable secondary constructors with bodies

To try this feature out, enable the `-language-version 1.9` compiler option. In a Gradle project, you can do so by adding the following to your `build.gradle(.kts)`:

Kotlin

```
tasks
    .withType<org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask<*>>()
    .configureEach {
        compilerOptions
            .languageVersion
            .set(
                org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
            )
    }
```

Groovy

```
tasks
    .withType(org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class)
    .configureEach {
        compilerOptions.languageVersion =
            org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
    }
```

We encourage you to try this feature out and submit all reports in YouTrack to help us make it the default in Kotlin 1.9.0.

Learn more about the development of Kotlin inline classes in this KEEP.

New Kotlin/Wasm target

Kotlin/Wasm (Kotlin WebAssembly) goes Experimental in this release. The Kotlin team finds WebAssembly to be a promising technology and wants to find better ways for you to use it and get all of the benefits of Kotlin.

WebAssembly binary format is independent of the platform because it runs using its own virtual machine. Almost all modern browsers already support WebAssembly 1.0. To set up the environment to run WebAssembly, you only need to enable an experimental garbage collection mode that Kotlin/Wasm targets. You can find detailed instructions here: How to enable Kotlin/Wasm.

We want to highlight the following advantages of the new Kotlin/Wasm target:

- Faster compilation speed compared to the `wasm32` Kotlin/Native target, since Kotlin/Wasm doesn't have to use LLVM.
- Easier interoperability with JS and integration with browsers compared to the `wasm32` target, thanks to the Wasm garbage collection.
- Potentially faster application startup compared to Kotlin/JS and JavaScript because Wasm has a compact and easy-to-parse bytecode.
- Improved application runtime performance compared to Kotlin/JS and JavaScript because Wasm is a statically typed language.

Starting with the 1.8.20 release, you can use Kotlin/Wasm in your experimental projects. We provide the Kotlin standard library (`stdlib`) and test library (`kotlin.test`) for Kotlin/Wasm out of the box. IDE support will be added in future releases.

Learn more about Kotlin/Wasm in this YouTube video.

How to enable Kotlin/Wasm

To enable and test Kotlin/Wasm, update your `build.gradle.kts` file:

```
plugins {
    kotlin("multiplatform") version "1.8.20"
}

kotlin {
    wasm {
        binaries.executable()
        browser {
        }
    }
    sourceSets {
        val commonMain by getting
        val commonTest by getting {
            dependencies {
                implementation(kotlin("test"))
            }
        }
        val wasmMain by getting
        val wasmTest by getting
    }
}
```

Check out the GitHub repository with Kotlin/Wasm examples.

To run a Kotlin/Wasm project, you need to update the settings of the target environment:

Chrome

- For version 109:

  Run the application with the `--js-flags=--experimental-wasm-gc` command line argument.
- For version 110 or later:
  1. Go to `chrome://flags/#enable-webassembly-garbage-collection` in your browser.
  2. Enable **WebAssembly Garbage Collection**.
  3. Relaunch your browser.

Firefox

For version 109 or later:

1. Go to `about:config` in your browser.
2. Enable `javascript.options.wasm_function_references` and `javascript.options.wasm_gc` options.
3. Relaunch your browser.

Edge

For version 109 or later:

Run the application with the `--js-flags=--experimental-wasm-gc` command line argument.

Leave your feedback on Kotlin/Wasm

We would appreciate any feedback you may have!

- Provide your feedback directly to developers in Kotlin Slack – get an invite and join the #webassembly channel.
- Report any problems you faced with Kotlin/Wasm on this YouTrack issue.

Kotlin/JVM

Kotlin 1.8.20 introduces a preview of Java synthetic property references and support for the JVM IR backend in the kapt stub generating task by default.

Preview of Java synthetic property references

> This feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.8.20 introduces the ability to create references to Java synthetic properties, for example, for such Java code:

```
public class Person {
    private String name;
    private int age;

    public Person(String name, int age) {
        this.name = name;
        this.age = age;
    }

    public String getName() {
        return name;
    }

    public int getAge() {
        return age;
    }
}
```

Kotlin has always allowed you to write `person.age`, where `age` is a synthetic property. Now, you can also create references to `Person::age` and `person::age`. All the same works for `name`, as well.

```
val persons = listOf(Person("Jack", 11), Person("Sofie", 12), Person("Peter", 11))
    persons
        // Call a reference to Java synthetic property:
        .sortedBy(Person::age)
        // Call Java getter via the Kotlin property syntax:
        .forEach { person -> println(person.name) }
```

How to enable Java synthetic property references

To try this feature out, enable the `-language-version 1.9` compiler option. In a Gradle project, you can do so by adding the following to your `build.gradle(.kts)`:

Kotlin

```
tasks
    .withType<org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask<*>>()
    .configureEach {
        compilerOptions
            .languageVersion
            .set(
                org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
            )
    }
```

Groovy

```
tasks
    .withType(org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class)
    .configureEach {
        compilerOptions.languageVersion =
            org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
    }
```

Support for the JVM IR backend in kapt stub generating task by default

In Kotlin 1.7.20, we introduced support for the JVM IR backend in the kapt stub generating task. Starting with this release, this support works by default. You no longer need to specify `kapt.use.jvm.ir=true` in your `gradle.properties` to enable it. We would appreciate your feedback on this feature in YouTrack.

Kotlin/Native

Kotlin 1.8.20 includes changes to supported Kotlin/Native targets, interoperability with Objective-C, and improvements to the CocoaPods Gradle plugin, among other updates:

- Update for Kotlin/Native targets
- Deprecation of the legacy memory manager
- Support for Objective-C headers with @import directives
- Support for link-only mode in the Cocoapods Gradle plugin
- Import Objective-C extensions as class members in UIKit
- Reimplementation of compiler cache management in the compiler
- Deprecation of `useLibraries()` in Cocoapods Gradle plugin

Update for Kotlin/Native targets

The Kotlin team decided to revisit the list of targets supported by Kotlin/Native, split them into tiers, and deprecate some of them starting with Kotlin 1.8.20. See the Kotlin/Native target support section for the full list of supported and deprecated targets.

The following targets have been deprecated with Kotlin 1.8.20 and will be removed in 1.9.20:

- `iosArm32`
- `watchosX86`
- `wasm32`
- `mingwX86`
- `linuxArm32Hfp`
- `linuxMips32`
- `linuxMipsel32`

As for the remaining targets, there are now three tiers of support depending on how well a target is supported and tested in the Kotlin/Native compiler. A target can be moved to a different tier. For example, we'll do our best to provide full support for `iosArm64` in the future, as it is important for Kotlin Multiplatform.

If you're a library author, these target tiers can help you decide which targets to test on CI tools and which ones to skip. The Kotlin team will use the same approach when developing official Kotlin libraries, like kotlinx.coroutines.

Check out our blog post to learn more about the reasons for these changes.

Deprecation of the legacy memory manager

Starting with 1.8.20, the legacy memory manager is deprecated and will be removed in 1.9.20. The new memory manager was enabled by default in 1.7.20 and has been receiving further stability updates and performance improvements.

If you're still using the legacy memory manager, remove the `kotlin.native.binary.memoryModel=strict` option from your `gradle.properties` and follow our Migration guide to make the necessary changes.

The new memory manager doesn't support the `wasm32` target. This target is also deprecated starting with this release and will be removed in 1.9.20.

Support for Objective-C headers with @import directives

> This feature is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin/Native can now import Objective-C headers with `@import` directives. This feature is useful for consuming Swift libraries that have auto-generated Objective-C headers or classes of CocoaPods dependencies written in Swift.

Previously, the cinterop tool failed to analyze headers that depended on Objective-C modules via the `@import` directive. The reason was that it lacked support for the `-fmodules` option.

Starting with Kotlin 1.8.20, you can use Objective-C headers with `@import`. To do so, pass the `-fmodules` option to the compiler in the definition file as `compilerOpts`. If you use CocoaPods integration, specify the cinterop option in the configuration block of the `pod()` function like this:

```
kotlin {
    ios()

    cocoapods {
        summary = "CocoaPods test library"
        homepage = "https://github.com/JetBrains/kotlin"

        ios.deploymentTarget = "13.5"

        pod("PodName") {
            extraOpts = listOf("-compiler-option", "-fmodules")
        }
    }
}
```

This was a highly awaited feature, and we welcome your feedback about it in YouTrack to help us make it the default in future releases.

Support for the link-only mode in Cocoapods Gradle plugin

With Kotlin 1.8.20, you can use Pod dependencies with dynamic frameworks only for linking, without generating cinterop bindings. This may come in handy when cinterop bindings are already generated.

Consider a project with 2 modules, a library and an app. The library depends on a Pod but doesn't produce a framework, only a `.klib`. The app depends on the library and produces a dynamic framework. In this case, you need to link this framework with the Pods that the library depends on, but you don't need cinterop bindings because they are already generated for the library.

To enable the feature, use the `linkOnly` option or a builder property when adding a dependency on a Pod:

```
cocoapods {
    summary = "CocoaPods test library"
    homepage = "https://github.com/JetBrains/kotlin"

    pod("Alamofire", linkOnly = true) {
        version = "5.7.0"
    }
}
```

If you use this option with static frameworks, it will remove the Pod dependency entirely because Pods are not used for static framework linking.

Import Objective-C extensions as class members in UIKit

Since Xcode 14.1, some methods from Objective-C classes have been moved to category members. That led to the generation of a different Kotlin API, and these methods were imported as Kotlin extensions instead of methods.

You may have experienced issues resulting from this when overriding methods using UIKit. For example, it became impossible to override `drawRect()` or `layoutSubviews()` methods when subclassing a UIView in Kotlin.

Since 1.8.20, category members that are declared in the same headers as NSView and UIView classes are imported as members of these classes. This means that the methods subclassing from NSView and UIView can be easily overridden, like any other method.

If everything goes well, we're planning to enable this behavior by default for all of the Objective-C classes.

Reimplementation of compiler cache management in the compiler

To speed up the evolution of compiler caches, we've moved compiler cache management from the Kotlin Gradle plugin to the Kotlin/Native compiler. This unblocks work on several important improvements, including those to do with compilation times and compiler cache flexibility.

If you encounter some problem and need to return to the old behavior, use the `kotlin.native.cacheOrchestration=gradle` Gradle property.

We would appreciate your feedback on this in YouTrack.

Deprecation of useLibraries() in Cocoapods Gradle plugin

Kotlin 1.8.20 starts the deprecation cycle of the `useLibraries()` function used in the CocoaPods integration for static libraries.

We introduced the `useLibraries()` function to allow dependencies on Pods containing static libraries. With time, this case has become very rare. Most of the Pods are distributed by sources, and Objective-C frameworks or XCFrameworks are a common choice for binary distribution.

Since this function is unpopular and it creates issues that complicate the development of the Kotlin CocoaPods Gradle plugin, we've decided to deprecate it.

For more information on frameworks and XCFrameworks, see Build final native binaries.

Kotlin Multiplatform

Kotlin 1.8.20 strives to improve the developer experience with the following updates to Kotlin Multiplatform:

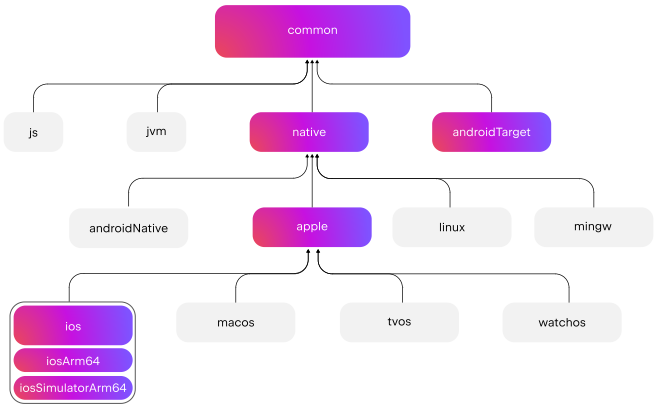
- New approach for setting up source set hierarchy
- Preview of Gradle composite builds support in Kotlin Multiplatform
- Improved output for Gradle errors in Xcode

New approach to source set hierarchy

> The new approach to source set hierarchy is Experimental. It may be changed in future Kotlin releases without prior notice. Opt-in is required (see the details below). We would appreciate your feedback in YouTrack.

Kotlin 1.8.20 offers a new way of setting up source set hierarchy in your multiplatform projects - the default target hierarchy. The new approach is intended to replace target shortcuts like `ios`, which have their design flaws.

The idea behind the default target hierarchy is simple: You explicitly declare all the targets to which your project compiles, and the Kotlin Gradle plugin automatically creates shared source sets based on the specified targets.



Set up your project

Consider this example of a simple multiplatform mobile app:

```
@OptIn(ExperimentalKotlinGradlePluginApi::class)
kotlin {
    // Enable the default target hierarchy:
    targetHierarchy.default()

    android()
    iosArm64()
    iosSimulatorArm64()
}
```

You can think of the default target hierarchy as a template for all possible targets and their shared source sets. When you declare the final targets `android`, `iosArm64`, and `iosSimulatorArm64` in your code, the Kotlin Gradle plugin finds suitable shared source sets from the template and creates them for you. The resulting hierarchy looks like this:

An example of using the default target hierarchy

Green source sets are actually created and present in the project, while gray ones from the default template are ignored. As you can see, the Kotlin Gradle plugin hasn't created the `watchos` source set, for example, because there are no watchOS targets in the project.

If you add a watchOS target, such as `watchosArm64`, the `watchos` source set is created, and the code from the `apple`, `native`, and `common` source sets is compiled to `watchosArm64`, as well.

You can find the complete scheme for the default target hierarchy in the documentation.

In this example, the `apple` and `native` source sets compile only to the `iosArm64` and `iosSimulatorArm64` targets. Therefore, despite their names, they have access to the full iOS API. This might be counter-intuitive for source sets like `native`, as you may expect that only APIs available on all native targets are accessible in this source set. This behavior may change in the future.

Why replace shortcuts

Creating source sets hierarchies can be verbose, error-prone, and unfriendly for beginners. Our previous solution was to introduce shortcuts like `ios` that create a part of the hierarchy for you. However, working with shortcuts proved they have a big design flaw: they're difficult to change.

Take the `ios` shortcut, for example. It creates only the `iosArm64` and `iosX64` targets, which can be confusing and may lead to issues when working on an M1-based host that requires the `iosSimulatorArm64` target as well. However, adding the `iosSimulatorArm64` target can be a very disruptive change for user projects:

- All dependencies used in the `iosMain` source set have to support the `iosSimulatorArm64` target; otherwise, the dependency resolution fails.
- Some native APIs used in `iosMain` may disappear when adding a new target (though this is unlikely in the case of `iosSimulatorArm64`).
- In some cases, such as when writing a small pet project on your Intel-based MacBook, you might not even need this change.

It became clear that shortcuts didn't solve the problem of configuring hierarchies, which is why we stopped adding new shortcuts at some point.

The default target hierarchy may look similar to shortcuts at first glance, but they have a crucial distinction: **users have to explicitly specify the set of targets**. This set defines how your project is compiled and published and how it participates in dependency resolution. Since this set is fixed, changes to the default configuration from the Kotlin Gradle plugin should cause significantly less distress in the ecosystem, and it will be much easier to provide tooling-assisted migration.

How to enable the default hierarchy

This new feature is Experimental. For Kotlin Gradle build scripts, you need to opt in with `@OptIn(ExperimentalKotlinGradlePluginApi::class)`.

For more information, see Hierarchical project structure.

Leave feedback

This is a significant change to multiplatform projects. We would appreciate your feedback to help make it even better.

Preview of Gradle composite builds support in Kotlin Multiplatform

> This feature has been supported in Gradle builds since Kotlin Gradle Plugin 1.8.20. For IDE support, use IntelliJ IDEA 2023.1 Beta 2 (231.8109.2) or later and the Kotlin Gradle plugin 1.8.20 with any Kotlin IDE plugin.

Starting with 1.8.20, Kotlin Multiplatform supports Gradle composite builds. Composite builds allow you to include builds of separate projects or parts of the same project into a single build.

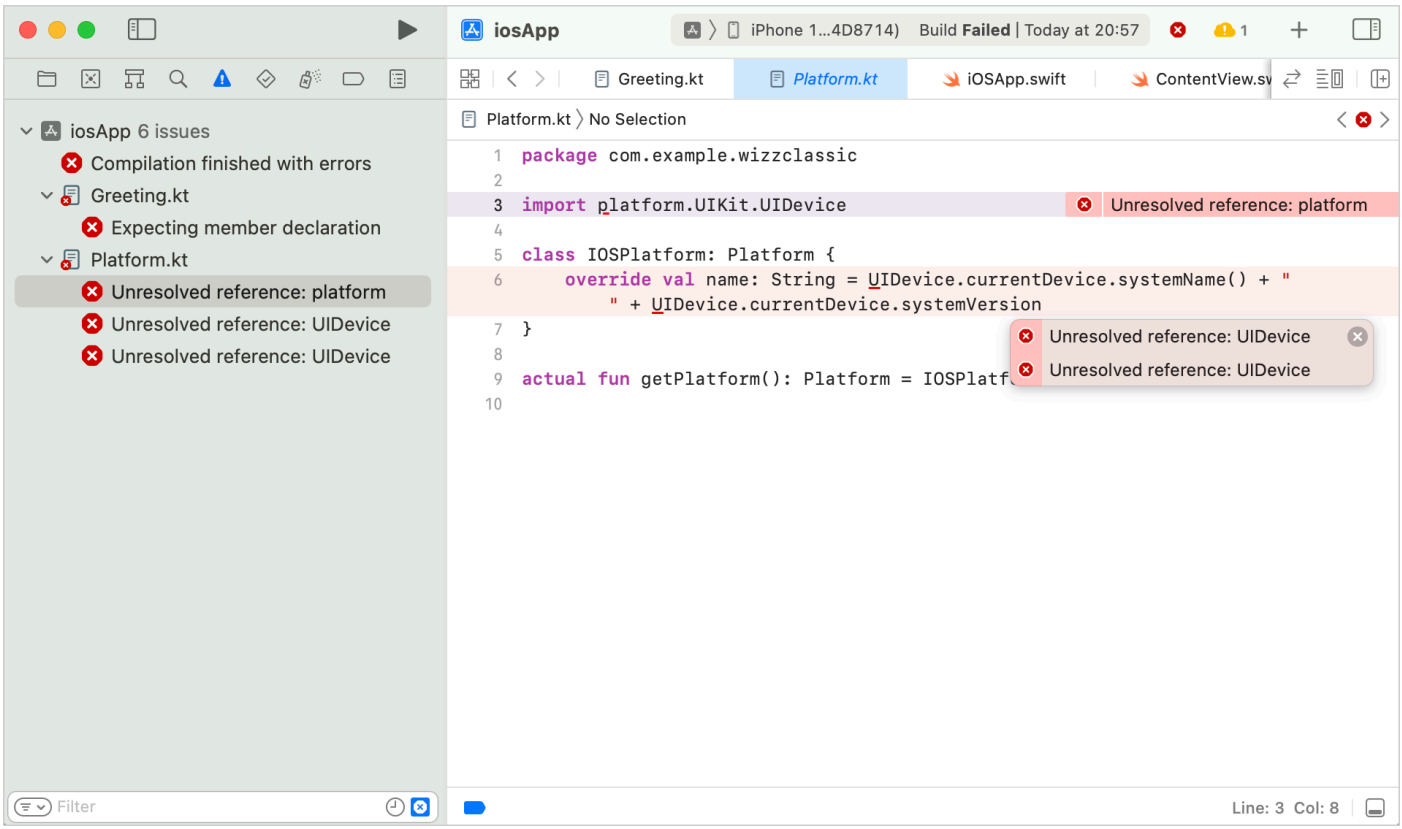
Due to some technical challenges, using Gradle composite builds with Kotlin Multiplatform was only partially supported. Kotlin 1.8.20 contains a preview of the improved support that should work with a larger variety of projects. To try it out, add the following option to your `gradle.properties`:

```
kotlin.mpp.import.enableKgpDependencyResolution=true
```

This option enables a preview of the new import mode. Besides the support for composite builds, it provides a smoother import experience in multiplatform projects, as we've included major bug fixes and improvements to make the import more stable.

Known issues

It's still a preview version that needs further stabilization, and you might encounter some issues with import along the way. Here are some known issues we're planning to fix before the final release of Kotlin 1.8.20:



- There's no Kotlin 1.8.20 plugin available for IntelliJ IDEA 2023.1 EAP yet. Despite that, you can still set the Kotlin Gradle plugin version to 1.8.20 and try out composite builds in this IDE.
- If your projects include builds with a specified `rootProject.name`, composite builds may fail to resolve the Kotlin metadata. For the workaround and details, see this Youtrack issue.

We encourage you to try it out and submit all reports on YouTrack to help us make it the default in Kotlin 1.9.0.

Improved output for Gradle errors in Xcode

If you had issues building your multiplatform projects in Xcode, you might have encountered a "Command PhaseScriptExecution failed with a nonzero exit code" error. This message signals that the Gradle invocation has failed, but it's not very helpful when trying to detect the problem.

Starting with Kotlin 1.8.20, Xcode can parse the output from the Kotlin/Native compiler. Furthermore, in case the Gradle build fails, you'll see an additional error message from the root cause exception in Xcode. In most cases, it'll help to identify the root problem.

Improved output for Gradle errors in Xcode

The new behavior is enabled by default for the standard Gradle tasks for Xcode integration, like `embedAndSignAppleFrameworkForXcode` that can connect the iOS framework from your multiplatform project to the iOS application in Xcode. It can also be enabled (or disabled) with the `kotlin.native.useXcodeMessageStyle` Gradle property.

Kotlin/JavaScript

Kotlin 1.8.20 changes the ways TypeScript definitions can be generated. It also includes a change designed to improve your debugging experience:

- Removal of Dukat integration from the Gradle plugin
- Kotlin variable and function names in source maps
- Opt in for generation of TypeScript definition files

Removal of Dukat integration from Gradle plugin

In Kotlin 1.8.20, we've removed our Experimental Dukat integration from the Kotlin/JavaScript Gradle plugin. The Dukat integration supported the automatic conversion of TypeScript declaration files (`.d.ts`) into Kotlin external declarations.

You can still convert TypeScript declaration files (`.d.ts`) into Kotlin external declarations by using our Dukat tool instead.

The Dukat tool is Experimental. It may be dropped or changed at any time.

Kotlin variable and function names in source maps

To help with debugging, we've introduced the ability to add the names that you declared in Kotlin code for variables and functions into your source maps. Prior to 1.8.20, these weren't available in source maps, so in the debugger, you always saw the variable and function names of the generated JavaScript.

You can configure what is added by using `sourceMapNamesPolicy` in your Gradle file `build.gradle.kts` , or the `-source-map-names-policy` compiler option. The table below lists the possible settings:

Setting	Description	Example output
`simple-names`	Variable names and simple function names are added. (Default)	`main`
`fully-qualified-names`	Variable names and fully qualified function names are added.	`com.example.kjs.playground.main`
`no`	No variable or function names are added.	N/A

See below for an example configuration in a `build.gradle.kts` file:

```
tasks.withType<org.jetbrains.kotlin.gradle.tasks.Kotlin2JsCompile>().configureEach {

compilercompileOptions.sourceMapNamesPolicy.set(org.jetbrains.kotlin.gradle.dsl.JsSourceMapNamesPolicy.S
// or SOURCE_MAP_NAMES_POLICY_NO, or SOURCE_MAP_NAMES_POLICY_SIMPLE_NAMES
}
```

Debugging tools like those provided in Chromium-based browsers can pick up the original Kotlin names from your source map to improve the readability of your stack trace. Happy debugging!

The addition of variable and function names in source maps is Experimental. It may be dropped or changed at any time.

Opt in for generation of TypeScript definition files

Previously, if you had a project that produced executable files (`binaries.executable()`), the Kotlin/JS IR compiler collected any top-level declarations marked with `@JsExport` and automatically generated TypeScript definitions in a `.d.ts` file.

As this isn't useful for every project, we've changed the behavior in Kotlin 1.8.20. If you want to generate TypeScript definitions, you have to explicitly configure this in your Gradle build file. Add `generateTypeScriptDefinitions()` to your `build.gradle.kts.file` in the `js` section. For example:

```
kotlin {
    js {
        binaries.executable()
        browser {
        }
        generateTypeScriptDefinitions()
    }
}
```

The generation of TypeScript definitions (`d.ts`) is Experimental. It may be dropped or changed at any time.

Gradle

Kotlin 1.8.20 is fully compatible with Gradle 6.8 through 7.6 except for some special cases in the Multiplatform plugin. You can also use Gradle versions up to the latest Gradle release, but if you do, keep in mind that you might encounter deprecation warnings or some new Gradle features might not work.

This version brings the following changes:

- New alignment of Gradle plugins' versions
- New JVM incremental compilation by default in Gradle
- Precise backup of compilation tasks' outputs
- Lazy Kotlin/JVM task creation for all Gradle versions
- Non-default location of compile tasks' destinationDirectory
- Ability to opt-out from reporting compiler arguments to an HTTP statistics service

New Gradle plugins versions alignment

Gradle provides a way to ensure dependencies that must work together are always aligned in their versions. Kotlin 1.8.20 adopted this approach, too. It works by default so that you don't need to change or update your configuration to enable it. In addition, you no longer need to resort to this workaround for resolving Kotlin Gradle plugins' transitive dependencies.

We would appreciate your feedback on this feature in YouTrack.

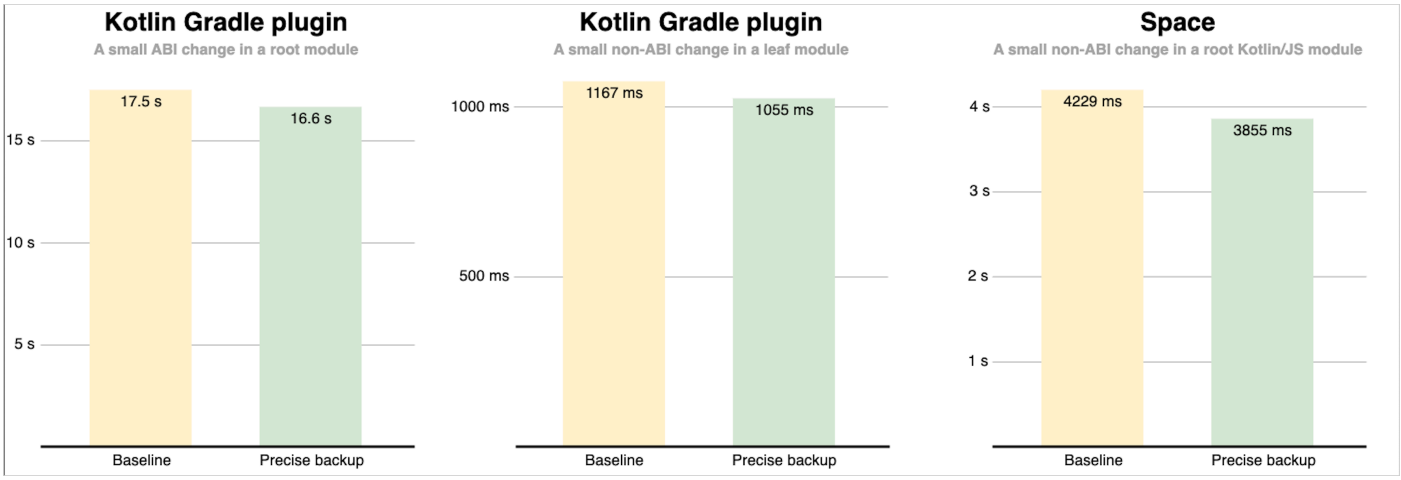
New JVM incremental compilation by default in Gradle

The new approach to incremental compilation, which has been available since Kotlin 1.7.0, now works by default. You no longer need to specify `kotlin.incremental.useClasspathSnapshot=true` in your `gradle.properties` to enable it.

We would appreciate your feedback on this. You can file an issue in YouTrack.

Precise backup of compilation tasks' outputs

> Precise backup of compilation tasks' outputs is Experimental. To use it, add `kotlin.compiler.preciseCompilationResultsBackup=true` to `gradle.properties`. We would appreciate your feedback on it in YouTrack.



Starting with Kotlin 1.8.20, you can enable precise backup, whereby only those classes that Kotlin recompiles in the incremental compilation will be backed up. Both full and precise backups help to run builds incrementally again after compilation errors. Precise backup also saves build time compared to full backup. Full backup may take **noticeable** build time in large projects or if many tasks are making backups, especially if a project is located on a slow HDD.

This optimization is Experimental. You can enable it by adding the `kotlin.compiler.preciseCompilationResultsBackup` Gradle property to the `gradle.properties` file:

```
kotlin.compiler.preciseCompilationResultsBackup=true
```

Example of precise backup usage in JetBrains

In the following charts, you can see examples of using precise backup compared to full backup:

Comparison of full and precise backups

The first and second charts show how precise backup in the Kotlin project affects building the Kotlin Gradle plugin:

1. After making a small ABI change – adding a new public method – to a module that lots of modules depend on.
2. After making a small non-ABI change – adding a private function – to a module that no other modules depend on.

The third chart shows how precise backup in the Space project affects building a web frontend after a small non-ABI change – adding a private function – to a Kotlin/JS module that lots of modules depend on.

These measurements were performed on a computer with the Apple M1 Max CPU; different computers will yield slightly different results. The factors affecting performance include but are not limited to:

- How warm the Kotlin daemon and the Gradle daemon are.
- How fast or slow the disk is.
- The CPU model and how busy it is.
- Which modules are affected by the changes and how big these modules are.
- Whether the changes are ABI or non-ABI.

Evaluating optimizations with build reports

To estimate the impact of the optimization on your computer for your project and your scenarios, you can use Kotlin build reports. Enable reports in the text file format by adding the following property to your `gradle.properties` file:

```
kotlin.build.report.output=file
```

Here is an example of a relevant part of the report before enabling precise backup:

```
Task ':kotlin-gradle-plugin:compileCommonKotlin' finished in 0.59 s
<...>
Time metrics:
 Total Gradle task time: 0.59 s
 Task action before worker execution: 0.24 s
  Backup output: 0.22 s // Pay attention to this number
<...>
```

And here is an example of a relevant part of the report after enabling precise backup:

```
Task ':kotlin-gradle-plugin:compileCommonKotlin' finished in 0.46 s
<...>
Time metrics:
 Total Gradle task time: 0.46 s
 Task action before worker execution: 0.07 s
  Backup output: 0.05 s // The time has reduced
 Run compilation in Gradle worker: 0.32 s
  Clear jar cache: 0.00 s
  Precise backup output: 0.00 s // Related to precise backup
  Cleaning up the backup stash: 0.00 s // Related to precise backup
<...>
```

Lazy Kotlin/JVM tasks creation for all Gradle versions

For projects with the `org.jetbrains.kotlin.gradle.jvm` plugin on Gradle 7.3+, the Kotlin Gradle plugin no longer creates and configures the task `compileKotlin` eagerly. On lower Gradle versions, it simply registers all the tasks and doesn't configure them on a dry run. The same behavior is now in place when using Gradle 7.3+.

Non-default location of compile tasks' destinationDirectory

Update your build script with some additional code if you do one of the following:

- Override the Kotlin/JVM `KotlinJvmCompile` / `KotlinCompile` task's `destinationDirectory` location.
- Use a deprecated Kotlin/JS/Non-IR variant and override the `Kotlin2JsCompile` task's `destinationDirectory`.

You need to explicitly add `sourceSets.main.kotlin.classesDirectories` to `sourceSets.main.outputs` in your JAR file:

```
tasks.jar(type: Jar) {
    from sourceSets.main.outputs
    from sourceSets.main.kotlin.classesDirectories
}
```

Ability to opt-out from reporting compiler arguments to an HTTP statistics service

You can now control whether the Kotlin Gradle plugin should include compiler arguments in HTTP build reports. Sometimes, you might not need the plugin to report these arguments. If a project contains many modules, its compiler arguments in the report can be very heavy and not that helpful. There is now a way to disable it and thus save memory. In your `gradle.properties` or `local.properties`, use the `kotlin.build.report.include_compiler_arguments=(true|false)` property.

We would appreciate your feedback on this feature on YouTrack.

Standard library

Kotlin 1.8.20 adds a variety of new features, including some that are particularly useful for Kotlin/Native development:

- Support for the AutoCloseable interface
- Support for Base64 encoding and decoding
- Support for @Volatile in Kotlin/Native
- Bug fix for stack overflow when using regex in Kotlin/Native

Support for the AutoCloseable interface

> The new `AutoCloseable` interface is Experimental, and to use it you need to opt in with `@OptIn(ExperimentalStdlibApi::class)` or the compiler argument `-opt-in=kotlin.ExperimentalStdlibApi`.

The `AutoCloseable` interface has been added to the common standard library so that you can use one common interface for all libraries to close resources. In Kotlin/JVM, the `AutoCloseable` interface is an alias for `java.lang.AutoClosable`.

In addition, the extension function `use()` is now included, which executes a given block function on the selected resource and then closes it down correctly, whether an exception is thrown or not.

There is no public class in the common standard library that implements the `AutoCloseable` interface. In the example below, we define the `XMLWriter` interface and assume that there is a resource that implements it. For example, this resource could be a class that opens a file, writes XML content, and then closes it.

```
interface XMLWriter : AutoCloseable {
    fun document(encoding: String, version: String, content: XMLWriter.() -> Unit)
    fun element(name: String, content: XMLWriter.() -> Unit)
    fun attribute(name: String, value: String)
    fun text(value: String)
}

fun writeBooksTo(writer: XMLWriter) {
    writer.use { xml ->
        xml.document(encoding = "UTF-8", version = "1.0") {
            element("bookstore") {
                element("book") {
                    attribute("category", "fiction")
                    element("title") { text("Harry Potter and the Prisoner of Azkaban") }
                    element("author") { text("J. K. Rowling") }
                    element("year") { text("1999") }
                    element("price") { text("29.99") }
                }
                element("book") {
                    attribute("category", "programming")
                    element("title") { text("Kotlin in Action") }
                    element("author") { text("Dmitry Jemerov") }
                    element("author") { text("Svetlana Isakova") }
                    element("year") { text("2017") }
                    element("price") { text("25.19") }
                }
            }
        }
    }
}
```

Support for Base64 encoding

The new encoding and decoding functionality is Experimental, and to use it, you need to opt in with `@OptIn(ExperimentalEncodingApi::class)` or the compiler argument `-opt-in=kotlin.io.encoding.ExperimentalEncodingApi`.

We've added support for Base64 encoding and decoding. We provide 3 class instances, each using different encoding schemes and displaying different behaviors. Use the `Base64.Default` instance for the standard Base64 encoding scheme.

Use the `Base64.UrlSafe` instance for the "URL and Filename safe" encoding scheme.

Use the `Base64.Mime` instance for the MIME encoding scheme. When you use the `Base64.Mime` instance, all encoding functions insert a line separator every 76 characters. In the case of decoding, any illegal characters are skipped and don't throw an exception.

The `Base64.Default` instance is the companion object of the `Base64` class. As a result, you can call its functions via `Base64.encode()` and `Base64.decode()` instead of `Base64.Default.encode()` and `Base64.Default.decode()`.

```
val foBytes = "fo".map { it.code.toByte() }.toByteArray()
Base64.Default.encode(foBytes) // "Zm8="
// Alternatively:
// Base64.encode(foBytes)

val foobarBytes = "foobar".map { it.code.toByte() }.toByteArray()
Base64.UrlSafe.encode(foobarBytes) // "Zm9vYmFy"

Base64.Default.decode("Zm8=") // foBytes
// Alternatively:
// Base64.decode("Zm8=")

Base64.UrlSafe.decode("Zm9vYmFy") // foobarBytes
```

You can use additional functions to encode or decode bytes into an existing buffer, as well as to append the encoding result to a provided `Appendable` type object.

In Kotlin/JVM, we've also added the extension functions `encodingWith()` and `decodingWith()` to enable you to perform Base64 encoding and decoding with input and output streams.

Support for @Volatile in Kotlin/Native

`@Volatile` in Kotlin/Native is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

If you annotate a `var` property with `@Volatile`, then the backing field is marked so that any reads or writes to this field are atomic, and writes are always made visible to other threads.

Prior to 1.8.20, the `kotlin.jvm.Volatile` annotation was available in the common standard library. However, this annotation is only effective in the JVM. If you use it in Kotlin/Native, it is ignored, which can lead to errors.

In 1.8.20, we've introduced a common annotation, `kotlin.concurrent.Volatile`, that you can use in both the JVM and Kotlin/Native.

How to enable

To try this feature out, opt in with `@OptIn(ExperimentalStdlibApi)` and enable the `-language-version 1.9` compiler option. In a Gradle project, you can do so by adding the following to your `build.gradle(.kts)` file:

Kotlin

```
tasks
    .withType<org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask<*>>()
    .configureEach {
        compilerOptions
            .languageVersion
            .set(
                org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
            )
    }
```

Groovy

```
tasks
    .withType(org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask.class)
    .configureEach {
        compilerOptions.languageVersion =
            org.jetbrains.kotlin.gradle.dsl.KotlinVersion.KOTLIN_1_9
    }
```

Bug fix for stack overflow when using regex in Kotlin/Native

In previous versions of Kotlin, a crash could occur if your regex input contained a large number of characters, even when the regex pattern was very simple. In 1.8.20, this issue has been resolved. For more information, see KT-46211.

Serialization updates

Kotlin 1.8.20 comes with Alpha support for the Kotlin K2 compiler and prohibits serializer customization via companion object.

Prototype serialization compiler plugin for Kotlin K2 compiler

Support for the serialization compiler plugin for K2 is in Alpha. To use it, enable the Kotlin K2 compiler.

Starting with 1.8.20, the serialization compiler plugin works with the Kotlin K2 compiler. Give it a try and share your feedback with us!

Prohibit implicit serializer customization via companion object

Currently, it is possible to declare a class as serializable with the `@Serializable` annotation and, at the same time, declare a custom serializer with the `@Serializer` annotation on its companion object.

For example:

```
import kotlinx.serialization.*

@Serializable
class Foo(val a: Int) {
    @Serializer(Foo::class)
    companion object {
        // Custom implementation of KSerializer<Foo>
    }
}
```

In this case, it's not clear from the `@Serializable` annotation which serializer is used. In actual fact, class `Foo` has a custom serializer.

To prevent this kind of confusion, in Kotlin 1.8.20 we've introduced a compiler warning for when this scenario is detected. The warning includes a possible migration path to resolve this issue.

If you use such constructs in your code, we recommend updating them to the below:

```
import kotlinx.serialization.*

@Serializable(Foo.Companion::class)
class Foo(val a: Int) {
    // Doesn't matter if you use @Serializer(Foo::class) or not
    companion object: KSerializer<Foo> {
        // Custom implementation of KSerializer<Foo>
    }
}
```

With this approach, it is clear that the `Foo` class uses the custom serializer declared in the companion object. For more information, see our YouTrack ticket.

> In Kotlin 2.0, we plan to promote the compile warning to a compiler error. We recommend that you migrate your code if you see this warning.

Documentation updates

The Kotlin documentation has received some notable changes:

- Get started with Spring Boot and Kotlin – create a simple application with a database and learn more about the features of Spring Boot and Kotlin.
- Scope functions – learn how to simplify your code with useful scope functions from the standard library.
- CocoaPods integration – set up an environment to work with CocoaPods.

Install Kotlin 1.8.20

Check the IDE version

IntelliJ IDEA 2022.2 and 2022.3 automatically suggest updating the Kotlin plugin to version 1.8.20. IntelliJ IDEA 2023.1 has the built-in Kotlin plugin 1.8.20.

Android Studio Flamingo (222) and Giraffe (223) will support Kotlin 1.8.20 in the next releases.

The new command-line compiler is available for download on the GitHub release page.

Configure Gradle settings

To download Kotlin artifacts and dependencies properly, update your `settings.gradle(.kts)` file to use the Maven Central repository:

```
pluginManagement {
    repositories {
        mavenCentral()
        gradlePluginPortal()
    }
}
```

If the repository is not specified, Gradle uses the sunset JCenter repository that could lead to issues with Kotlin artifacts.

What's new in Kotlin 1.8.0

Released: 28 December 2022

The Kotlin 1.8.0 release is out and here are some of its biggest highlights:

- New experimental functions for JVM: recursively copy or delete directory content
- Improved kotlin-reflect performance
- New -Xdebug compiler option for better debugging experience
- `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` merged into `kotlin-stdlib`
- Improved Objective-C/Swift interoperability
- Compatibility with Gradle 7.3

For information about the Kotlin release cycle, see Kotlin release process.

IDE support

The Kotlin plugin that supports 1.8.0 is available for:

IDE	Supported versions
IntelliJ IDEA	2021.3, 2022.1, 2022.2
Android Studio	Electric Eel (221), Flamingo (222)

You can update your projects to Kotlin 1.8.0 in IntelliJ IDEA 2022.3 without updating the IDE plugin.

To migrate existing projects to Kotlin 1.8.0 in IntelliJ IDEA 2022.3, change the Kotlin version to `1.8.0` and reimport your Gradle or Maven project.

Kotlin/JVM

Starting with version 1.8.0, the compiler can generate classes with a bytecode version corresponding to JVM 19. The new language version also includes:

- A compiler option for switching off the generation of JVM annotation targets
- A new `-Xdebug` compiler option for disabling optimizations
- The removal of the old backend
- Support for Lombok's @Builder annotation

Ability to not generate TYPE_USE and TYPE_PARAMETER annotation targets

If a Kotlin annotation has `TYPE` among its Kotlin targets, the annotation maps to `java.lang.annotation.ElementType.TYPE_USE` in its list of Java annotation targets. This is just like how the

`TYPE_PARAMETER` Kotlin target maps to the `java.lang.annotation.ElementType.TYPE_PARAMETER` Java target. This is an issue for Android clients with API levels less than 26, which don't have these targets in the API.

Starting with Kotlin 1.8.0, you can use the new compiler option `-Xno-new-java-annotation-targets` to avoid generating the `TYPE_USE` and `TYPE_PARAMETER` annotation targets.

A new compiler option for disabling optimizations

Kotlin 1.8.0 adds a new `-Xdebug` compiler option, which disables optimizations for a better debugging experience. For now, the option disables the "was optimized out" feature for coroutines. In the future, after we add more optimizations, this option will disable them, too.

The "was optimized out" feature optimizes variables when you use suspend functions. However, it is difficult to debug code with optimized variables because you don't see their values.

Never use this option in production: Disabling this feature via `-Xdebug` can cause memory leaks.

Removal of the old backend

In Kotlin 1.5.0, we announced that the IR-based backend became Stable. That meant that the old backend from Kotlin 1.4.* was deprecated. In Kotlin 1.8.0, we've removed the old backend completely. By extension, we've removed the compiler option `-Xuse-old-backend` and the Gradle `useOldBackend` option.

Support for Lombok's @Builder annotation

The community has added so many votes for the Kotlin Lombok: Support generated builders (@Builder) YouTrack issue that we just had to support the @Builder annotation.

We don't yet have plans to support the `@SuperBuilder` or `@Tolerate` annotations, but we'll reconsider if enough people vote for the @SuperBuilder and @Tolerate issues.

Learn how to configure the Lombok compiler plugin.

Kotlin/Native

Kotlin 1.8.0 includes changes to Objective-C and Swift interoperability, support for Xcode 14.1, and improvements to the CocoaPods Gradle plugin:

- Support for Xcode 14.1
- Improved Objective-C/Swift interoperability
- Dynamic frameworks by default in the CocoaPods Gradle plugin

Support for Xcode 14.1

The Kotlin/Native compiler now supports the latest stable Xcode version, 14.1. The compatibility improvements include the following changes:

- There's a new `watchosDeviceArm64` preset for the watchOS target that supports Apple watchOS on ARM64 platforms.
- The Kotlin CocoaPods Gradle plugin no longer has bitcode embedding for Apple frameworks by default.

- Platform libraries were updated to reflect the changes to Objective-C frameworks for Apple targets.

Improved Objective-C/Swift interoperability

To make Kotlin more interoperable with Objective-C and Swift, three new annotations were added:

- `@ObjCName` allows you to specify a more idiomatic name in Swift or Objective-C, instead of renaming the Kotlin declaration.

  The annotation instructs the Kotlin compiler to use a custom Objective-C and Swift name for this class, property, parameter, or function:

  ```
  @ObjCName(swiftName = "MySwiftArray")
  class MyKotlinArray {
      @ObjCName("index")
      fun indexOf(@ObjCName("of") element: String): Int = TODO()
  }

  // Usage with the ObjCName annotations
  let array = MySwiftArray()
  let index = array.index(of: "element")
  ```

- `@HiddenFromObjC` allows you to hide a Kotlin declaration from Objective-C.

  The annotation instructs the Kotlin compiler not to export a function or property to Objective-C and, consequently, Swift. This can make your Kotlin code more Objective-C/Swift-friendly.

- `@ShouldRefineInSwift` is useful for replacing a Kotlin declaration with a wrapper written in Swift.

  The annotation instructs the Kotlin compiler to mark a function or property as `swift_private` in the generated Objective-C API. Such declarations get the `__` prefix, which makes them invisible to Swift code.

  You can still use these declarations in your Swift code to create a Swift-friendly API, but they won't be suggested by Xcode's autocompletion, for example.

  For more information on refining Objective-C declarations in Swift, see the official Apple documentation.

> The new annotations require opt-in.

The Kotlin team is very grateful to Rick Clephas for implementing these annotations.

Dynamic frameworks by default in the CocoaPods Gradle plugin

Starting with Kotlin 1.8.0, Kotlin frameworks registered by the CocoaPods Gradle plugin are linked dynamically by default. The previous static implementation was inconsistent with the behavior of the Kotlin Gradle plugin.

```
kotlin {
    cocoapods {
        framework {
            baseName = "MyFramework"
            isStatic = false // Now dynamic by default
        }
    }
}
```

If you have an existing project with a static linking type and you upgrade to Kotlin 1.8.0 (or change the linking type explicitly), you may encounter an error with the project's execution. To fix it, close your Xcode project and run `pod install` in the Podfile directory.

For more information, see the CocoaPods Gradle plugin DSL reference.

Kotlin Multiplatform: A new Android source set layout

Kotlin 1.8.0 introduces a new Android source set layout that replaces the previous naming schema for directories, which is confusing in multiple ways.

Consider an example of two `androidTest` directories created in the current layout. One is for `KotlinSourceSets` and the other is for `AndroidSourceSets`:

- They have different semantics: Kotlin's `androidTest` belongs to the `unitTest` type, whereas Android's belongs to the `integrationTest` type.
- They create a confusing `SourceDirectories` layout, as `src/androidTest/kotlin` has a `UnitTest` and `src/androidTest/java` has an `InstrumentedTest`.
- Both `KotlinSourceSets` and `AndroidSourceSets` use a similar naming schema for Gradle configurations, so the resulting configurations of `androidTest` for both Kotlin's and Android's source sets are the same: `androidTestImplementation`, `androidTestApi`, `androidTestRuntimeOnly`, and `androidTestCompileOnly`.

To address these and other existing issues, we've introduced a new Android source set layout. Here are some of the key differences between the two layouts:

KotlinSourceSet naming schema

Current source set layout	New source set layout
`targetName` + `AndroidSourceSet.name`	`targetName` + `AndroidVariantType`

`{AndroidSourceSet.name}` maps to `{KotlinSourceSet.name}` as follows:

	Current source set layout	New source set layout
main	androidMain	androidMain
test	androidTest	androidUnitTest
androidTest	androidAndroidTest	androidInstrumentedTest

SourceDirectories

Current source set layout	New source set layout
The layout adds additional `/kotlin` SourceDirectories	`src/{AndroidSourceSet.name}/kotlin`, `src/{KotlinSourceSet.name}/kotlin`

`{AndroidSourceSet.name}` maps to `{SourceDirectories included}` as follows:

	Current source set layout	New source set layout
main	src/androidMain/kotlin, src/main/kotlin, src/main/java	src/androidMain/kotlin, src/main/kotlin, src/main/java
test	src/androidTest/kotlin, src/test/kotlin, src/test/java	src/androidUnitTest/kotlin, src/test/kotlin, src/test/java
androidTest	src/androidAndroidTest/kotlin, src/androidTest/java	src/androidInstrumentedTest/kotlin, src/androidTest/java, src/androidTest/kotlin

The location of the AndroidManifest.xml file

Current source set layout	New source set layout
src/{AndroidSourceSet.name}/AndroidManifest.xml	src/{KotlinSourceSet.name}/AndroidManifest.xml

`{AndroidSourceSet.name}` maps to `{AndroidManifest.xml location}` as follows:

	Current source set layout	New source set layout
main	src/main/AndroidManifest.xml	src/androidMain/AndroidManifest.xml
debug	src/debug/AndroidManifest.xml	src/androidDebug/AndroidManifest.xml

The relation between Android and common tests

The new Android source set layout changes the relation between Android-instrumented tests (renamed to `androidInstrumentedTest` in the new layout) and common tests.

Previously, there was a default `dependsOn` relation between `androidAndroidTest` and `commonTest`. In practice, it meant the following:

- The code in `commonTest` was available in `androidAndroidTest`.
- `expect` declarations in `commonTest` had to have corresponding `actual` implementations in `androidAndroidTest`.

- Tests declared in `commonTest` were also running as Android instrumented tests.

In the new Android source set layout, the `dependsOn` relation is not added by default. If you prefer the previous behavior, manually declare this relation in your `build.gradle.kts` file:

```
kotlin {
    // ...
    sourceSets {
        val commonTest by getting
        val androidInstrumentedTest by getting {
            dependsOn(commonTest)
        }
    }
}
```

Support for Android flavors

Previously, the Kotlin Gradle plugin eagerly created source sets that correspond to Android source sets with `debug` and `release` build types or custom flavors like `demo` and `full`. It made them accessible by constructions like `val androidDebug by getting { ... }`.

In the new Android source set layout, those source sets are created in the `afterEvaluate` phase. It makes such expressions invalid, leading to errors like `org.gradle.api.UnknownDomainObjectException: KotlinSourceSet with name 'androidDebug' not found`.

To work around that, use the new `invokeWhenCreated()` API in your `build.gradle.kts` file:

```
kotlin {
    // ...
    sourceSets.invokeWhenCreated("androidFreeDebug") {
        // ...
    }
}
```

Configuration and setup

The new layout will become the default in future releases. You can enable it now with the following Gradle option:

```
kotlin.mpp.androidSourceSetLayoutVersion=2
```

The new layout requires Android Gradle plugin 7.0 or later and is supported in Android Studio 2022.3 and later.

The usage of the previous Android-style directories is now discouraged. Kotlin 1.8.0 marks the start of the deprecation cycle, introducing a warning for the current layout. You can suppress the warning with the following Gradle property:

```
kotlin.mpp.androidSourceSetLayoutVersion1.nowarn=true
```

Kotlin/JS

Kotlin 1.8.0 stabilizes the JS IR compiler backend and brings new features to JavaScript-related Gradle build scripts:

- Stable JS IR compiler backend
- New settings for reporting that yarn.lock has been updated
- Add test targets for browsers via Gradle properties
- New approach to adding CSS support to your project

Stable JS IR compiler backend

Starting with this release, the Kotlin/JS intermediate representation (IR-based) compiler backend is Stable. It took a while to unify infrastructure for all three backends, but they now work with the same IR for Kotlin code.

As a consequence of the stable JS IR compiler backend, the old one is deprecated from now on.

Incremental compilation is enabled by default along with the stable JS IR compiler.

If you still use the old compiler, switch your project to the new backend.

New settings for reporting that yarn.lock has been updated

If you use the `yarn` package manager, there are three new special Gradle settings that could notify you if the `yarn.lock` file has been updated. You can use these settings when you want to be notified if `yarn.lock` has been changed silently during the CI build process.

These three new Gradle properties are:

- `YarnLockMismatchReport`, which specifies how changes to the `yarn.lock` file are reported. You can use one of the following values:
  - `FAIL` fails the corresponding Gradle task. This is the default.
  - `WARNING` writes the information about changes in the warning log.
  - `NONE` disables reporting.
- `reportNewYarnLock`, which reports about the recently created `yarn.lock` file explicitly. By default, this option is disabled: it's a common practice to generate a new `yarn.lock` file at the first start. You can use this option to ensure that the file has been committed to your repository.
- `yarnLockAutoReplace`, which replaces `yarn.lock` automatically every time the Gradle task is run.

To use these options, update your build script file `build.gradle.kts` as follows:

```
import org.jetbrains.kotlin.gradle.targets.js.yarn.YarnLockMismatchReport
import org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension

rootProject.plugins.withType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin::class.java) {
    rootProject.the<YarnRootExtension>().yarnLockMismatchReport =
        YarnLockMismatchReport.WARNING // NONE | FAIL
    rootProject.the<YarnRootExtension>().reportNewYarnLock = false // true
    rootProject.the<YarnRootExtension>().yarnLockAutoReplace = false // true
}
```

Add test targets for browsers via Gradle properties

Starting with Kotlin 1.8.0, you can set test targets for different browsers right in the Gradle properties file. Doing so shrinks the size of the build script file as you no longer need to write all targets in `build.gradle.kts`.

You can use this property to define a list of browsers for all modules, and then add specific browsers in the build scripts of particular modules.

For example, the following line in your Gradle property file will run the test in Firefox and Safari for all modules:

```
kotlin.js.browser.karma.browsers=firefox,safari
```

See the full list of available values for the property on GitHub.

The Kotlin team is very grateful to Martynas Petuška for implementing this feature.

New approach to adding CSS support to your project

This release provides a new approach to adding CSS support to your project. We assume that this will affect a lot of projects, so don't forget to update your Gradle build script files as described below.

Before Kotlin 1.8.0, the `cssSupport.enabled` property was used to add CSS support:

```
browser {
    commonWebpackConfig {
        cssSupport.enabled = true
    }
}
```

Now you should use the `enabled.set()` method in the `cssSupport {}` block:

```
browser {
    commonWebpackConfig {
        cssSupport {
            enabled.set(true)
        }
    }
}
```

Gradle

Kotlin 1.8.0 **fully** supports Gradle versions 7.2 and 7.3. You can also use Gradle versions up to the latest Gradle release, but if you do, keep in mind that you might encounter deprecation warnings or some new Gradle features might not work.

This version brings lots of changes:

- Exposing Kotlin compiler options as Gradle lazy properties
- Bumping the minimum supported versions
- Ability to disable the Kotlin daemon fallback strategy
- Usage of the latest kotlin-stdlib version in transitive dependencies
- Obligatory check for JVM target compatibility equality of related Kotlin and Java compile tasks
- Resolution of Kotlin Gradle plugins' transitive dependencies

- Deprecations and removals

Exposing Kotlin compiler options as Gradle lazy properties

To expose available Kotlin compiler options as Gradle lazy properties and to integrate them better into the Kotlin tasks, we made lots of changes:

- Compile tasks have the new `compilerOptions` input, which is similar to the existing `kotlinOptions` but uses `Property` from the Gradle Properties API as the return type:

```
tasks.named("compileKotlin", org.jetbrains.kotlin.gradle.tasks.KotlinJvmCompile::class.java) {
    compilerOptions {
        useK2.set(true)
    }
}
```

- The Kotlin tools tasks `KotlinJsDce` and `KotlinNativeLink` have the new `toolOptions` input, which is similar to the existing `kotlinOptions` input.
- New inputs have the `@Nested` Gradle annotation. Every property inside the inputs has a related Gradle annotation, such as `@Input` or `@Internal`.
- The Kotlin Gradle plugin API artifact has two new interfaces:
  - `org.jetbrains.kotlin.gradle.tasks.KotlinCompilationTask`, which has the `compilerOptions` input and the `compileOptions()` method. All Kotlin compilation tasks implement this interface.
  - `org.jetbrains.kotlin.gradle.tasks.KotlinToolTask`, which has the `toolOptions` input and the `toolOptions()` method. All Kotlin tool tasks – `KotlinJsDce`, `KotlinNativeLink`, and `KotlinNativeLinkArtifactTask` – implement this interface.
- Some `compilerOptions` use the new types instead of the `String` type:
  - `JvmTarget`
  - `KotlinVersion` (for the `apiVersion` and the `languageVersion` inputs)
  - `JsMainFunctionExecutionMode`
  - `JsModuleKind`
  - `JsSourceMapEmbedMode`

  For example, you can use `compilerOptions.jvmTarget.set(JvmTarget.JVM_11)` instead of `kotlinOptions.jvmTarget = "11"`.

  The `kotlinOptions` types didn't change, and they are internally converted to `compilerOptions` types.
- The Kotlin Gradle plugin API is binary-compatible with previous releases. There are, however, some source and ABI-breaking changes in the `kotlin-gradle-plugin` artifact. Most of these changes involve additional generic parameters to some internal types. One important change is that the `KotlinNativeLink` task no longer inherits the `AbstractKotlinNativeCompile` task.
- `KotlinJsCompilerOptions.outputFile` and the related `KotlinJsOptions.outputFile` options are deprecated. Use the `Kotlin2JsCompile.outputFileProperty` task input instead.

The Kotlin Gradle plugin still adds the `KotlinJvmOptions` DSL to the Android extension:

```
android {
    kotlinOptions {
        jvmTarget = "11"
    }
}
```

This will be changed in the scope of this issue, when the `compilerOptions` DSL will be added to a module level.

Limitations

The `kotlinOptions` task input and the `kotlinOptions{...}` task DSL are in support mode and will be deprecated in upcoming releases. Improvements will be made only to `compilerOptions` and `toolOptions`.

Calling any setter or getter on `kotlinOptions` delegates to the related property in the `compilerOptions`. This introduces the following limitations:

- `compilerOptions` and `kotlinOptions` cannot be changed in the task execution phase (see one exception in the paragraph below).
- `freeCompilerArgs` returns an immutable `List<String>`, which means that, for example, `kotlinOptions.freeCompilerArgs.remove("something")` will fail.

Several plugins, including `kotlin-dsl` and the Android Gradle plugin (AGP) with Jetpack Compose enabled, try to modify the `freeCompilerArgs` attribute in the task execution phase. We've added a workaround for them in Kotlin 1.8.0. This workaround allows any build script or plugin to modify `kotlinOptions.freeCompilerArgs` in the execution phase but produces a warning in the build log. To disable this warning, use the new Gradle property `kotlin.options.suppressFreeCompilerArgsModificationWarning=true`. Gradle is going to add fixes for the `kotlin-dsl` plugin and AGP with Jetpack Compose enabled.

Bumping the minimum supported versions

Starting with Kotlin 1.8.0, the minimum supported Gradle version is 6.8.3 and the minimum supported Android Gradle plugin version is 4.1.3.

See the Kotlin Gradle plugin compatibility with available Gradle versions in our documentation

Ability to disable the Kotlin daemon fallback strategy

There is a new Gradle property `kotlin.daemon.useFallbackStrategy`, whose default value is `true`. When the value is `false`, builds fail on problems with the daemon's startup or communication. There is also a new `useDaemonFallbackStrategy` property in Kotlin compile tasks, which takes priority over the Gradle property if you use both. If there is insufficient memory to run the compilation, you can see a message about it in the logs.

The Kotlin compiler's fallback strategy is to run a compilation outside the Kotlin daemon if the daemon somehow fails. If the Gradle daemon is on, the compiler uses the "In process" strategy. If the Gradle daemon is off, the compiler uses the "Out of process" strategy. For more information, see Compiler execution strategy. Note that silent fallback to another strategy can consume a lot of system resources or lead to non-deterministic builds; see this YouTrack issue for more details.

Usage of the latest kotlin-stdlib version in transitive dependencies

If you explicitly write Kotlin version 1.8.0 or higher in your dependencies, for example: `implementation("org.jetbrains.kotlin:kotlin-stdlib:1.8.0")`, then the Kotlin Gradle Plugin will use that Kotlin version for transitive `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` dependencies. This is done to avoid class duplication from different stdlib versions (learn more about merging `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` into `kotlin-stdlib`). You can disable this behavior with the `kotlin.stdlib.jdk.variants.version.alignment` Gradle property:

```
kotlin.stdlib.jdk.variants.version.alignment=false
```

If you run into issues with version alignment, align all versions via the Kotlin BOM by declaring a platform dependency on `kotlin-bom` in your build script:

```
implementation(platform("org.jetbrains.kotlin:kotlin-bom:1.8.0"))
```

Learn about other cases and our suggested solutions in the documentation.

Obligatory check for JVM targets of related Kotlin and Java compile tasks

This section applies to your JVM project even if your source files are only in Kotlin and you don't use Java.

Starting from this release, the default value for the `kotlin.jvm.target.validation.mode` property is `error` for projects on Gradle 8.0+ (this version of Gradle has not been released yet), and the plugin will fail the build in the event of JVM target incompatibility.

The shift of the default value from `warning` to `error` is a preparation step for a smooth migration to Gradle 8.0. **We encourage you to set this property to `error`** and configure a toolchain or align JVM versions manually.

Learn more about what can go wrong if you don't check the targets' compatibility.

Resolution of Kotlin Gradle plugins' transitive dependencies

In Kotlin 1.7.0, we introduced support for Gradle plugin variants. Because of these plugin variants, a build classpath can have different versions of the Kotlin Gradle plugins that depend on different versions of some dependency, usually `kotlin-gradle-plugin-api`. This can lead to a resolution problem, and we would like to propose the following workaround, using the `kotlin-dsl` plugin as an example.

The `kotlin-dsl` plugin in Gradle 7.6 depends on the `org.jetbrains.kotlin.plugin.sam.with.receiver:1.7.10` plugin, which depends on `kotlin-gradle-plugin-api:1.7.10`. If you add the `org.jetbrains.kotlin.gradle.jvm:1.8.0` plugin, this `kotlin-gradle-plugin-api:1.7.10` transitive dependency may lead to a dependency resolution error because of a mismatch between the versions (`1.8.0` and `1.7.10`) and the variant attributes' `org.gradle.plugin.api-version` values. As a workaround, add this constraint to align the versions. This workaround may be needed until we implement the Kotlin Gradle Plugin libraries alignment platform, which is in the plans:

```
dependencies {
    constraints {
        implementation("org.jetbrains.kotlin:kotlin-sam-with-receiver:1.8.0")
    }
}
```

This constraint forces the `org.jetbrains.kotlin:kotlin-sam-with-receiver:1.8.0` version to be used in the build classpath for transitive dependencies. Learn more about one similar case in the Gradle issue tracker.

Deprecations and removals

In Kotlin 1.8.0, the deprecation cycle continues for the following properties and methods:

- In the notes for Kotlin 1.7.0 that the `KotlinCompile` task still had the deprecated Kotlin property `classpath`, which would be removed in future releases. Now, we've changed the deprecation level to `error` for the `KotlinCompile` task's `classpath` property. All compile tasks use the `libraries` input for a list of libraries required for compilation.
- We removed the `kapt.use.worker.api` property that allowed running kapt via the Gradle Workers API. By default, kapt has been using Gradle workers since Kotlin 1.3.70, and we recommend sticking to this method.
- In Kotlin 1.7.0, we announced the start of a deprecation cycle for the `kotlin.compiler.execution.strategy` property. In this release, we removed this property. Learn how to define a Kotlin compiler execution strategy in other ways.

Standard library

Kotlin 1.8.0:

- Updates JVM compilation target.
- Stabilizes a number of functions – TimeUnit conversion between Java and Kotlin, `cbrt()`, Java `Optionals` extension functions.
- Provides a preview for comparable and subtractable `TimeMarks`.
- Includes experimental extension functions for `java.nio.file.path`.
- Presents improved kotlin-reflect performance.

Updated JVM compilation target

In Kotlin 1.8.0, the standard libraries (`kotlin-stdlib`, `kotlin-reflect`, and `kotlin-script-*`) are compiled with JVM target 1.8. Previously, the standard libraries were compiled with JVM target 1.6.

Kotlin 1.8.0 no longer supports JVM targets 1.6 and 1.7. As a result, you no longer need to declare `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` separately in build scripts because the contents of these artifacts have been merged into `kotlin-stdlib`.

> If you have explicitly declared `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` as dependencies in your build scripts, then you should replace them with `kotlin-stdlib`.

Note that mixing different versions of stdlib artifacts could lead to class duplication or to missing classes. To avoid that, the Kotlin Gradle plugin can help you align stdlib versions.

cbrt()

The `cbrt()` function, which allows you to compute the real cube root of a `double` or `float`, is now Stable.

```
import kotlin.math.*

fun main() {
    val num = 27
    val negNum = -num

    println("The cube root of ${num.toDouble()} is: " +
            cbrt(num.toDouble()))
    println("The cube root of ${negNum.toDouble()} is: " +
            cbrt(negNum.toDouble()))
}
```

TimeUnit conversion between Java and Kotlin

The `toTimeUnit()` and `toDurationUnit()` functions in `kotlin.time` are now Stable. Introduced as Experimental in Kotlin 1.6.0, these functions improve interoperability between Kotlin and Java. You can now easily convert between Java `java.util.concurrent.TimeUnit` and Kotlin `kotlin.time.DurationUnit`. These functions are supported on the JVM only.

```
import kotlin.time.*

// For use from Java
fun wait(timeout: Long, unit: TimeUnit) {
    val duration: Duration = timeout.toDuration(unit.toDurationUnit())
    ...
}
```

Comparable and subtractable TimeMarks

> The new functionality of `TimeMarks` is Experimental, and to use it you need to opt in by using `@OptIn(ExperimentalTime::class)` or `@ExperimentalTime`.

Before Kotlin 1.8.0, if you wanted to calculate the time difference between multiple `TimeMarks` and **now**, you could only call `elapsedNow()` on one `TimeMark` at a time. This made it difficult to compare the results because the two `elapsedNow()` function calls couldn't be executed at exactly the same time.

To solve this, in Kotlin 1.8.0 you can subtract and compare `TimeMarks` from the same time source. Now you can create a new `TimeMark` instance to represent **now** and subtract other `TimeMarks` from it. This way, the results that you collect from these calculations are guaranteed to be relative to each other.

```
import kotlin.time.*
fun main() {
    val timeSource = TimeSource.Monotonic
    val mark1 = timeSource.markNow()
    Thread.sleep(500) // Sleep 0.5 seconds
    val mark2 = timeSource.markNow()

    // Before 1.8.0
    repeat(4) { n ->
        val elapsed1 = mark1.elapsedNow()
        val elapsed2 = mark2.elapsedNow()

        // Difference between elapsed1 and elapsed2 can vary depending
        // on how much time passes between the two elapsedNow() calls
        println("Measurement 1.${n + 1}: elapsed1=$elapsed1, " +
                "elapsed2=$elapsed2, diff=${elapsed1 - elapsed2}")
    }
    println()

    // Since 1.8.0
    repeat(4) { n ->
        val mark3 = timeSource.markNow()
        val elapsed1 = mark3 - mark1
        val elapsed2 = mark3 - mark2

        // Now the elapsed times are calculated relative to mark3,
        // which is a fixed value
        println("Measurement 2.${n + 1}: elapsed1=$elapsed1, " +
                "elapsed2=$elapsed2, diff=${elapsed1 - elapsed2}")
    }
    // It's also possible to compare time marks with each other
    // This is true, as mark2 was captured later than mark1
    println(mark2 > mark1)
}
```

This new functionality is particularly useful in animation calculations where you want to calculate the difference between, or compare, multiple `TimeMarks` representing different frames.

Recursive copying or deletion of directories

> These new functions for `java.nio.file.path` are Experimental. To use them, you need to opt in with `@OptIn(kotlin.io.path.ExperimentalPathApi::class)` or `@kotlin.io.path.ExperimentalPathApi`. Alternatively, you can use the compiler option `-opt-in=kotlin.io.path.ExperimentalPathApi`.

We have introduced two new extension functions for `java.nio.file.Path`, `copyToRecursively()` and `deleteRecursively()`, which allow you to recursively:

- Copy a directory and its contents to another destination.
- Delete a directory and its contents.

These functions can be very useful as part of a backup process.

Error handling

Using `copyToRecursively()`, you can define what should happen if an exception occurs while copying, by overloading the `onError` lambda function:

```
sourceRoot.copyToRecursively(destinationRoot, followLinks = false,
    onError = { source, target, exception →
        logger.logError(exception, "Failed to copy $source to $target")
        OnErrorResult.TERMINATE
    })
```

When you use `deleteRecursively()`, if an exception occurs while deleting a file or folder, then the file or folder is skipped. Once the deletion has completed, `deleteRecursively()` throws an `IOException` containing all the exceptions that occurred as suppressed exceptions.

File overwrite

If `copyToRecursively()` finds that a file already exists in the destination directory, then an exception occurs. If you want to overwrite the file instead, use the overload that has `overwrite` as an argument and set it to `true`:

```
fun setUpEnvironment(projectDirectory: Path, fixtureName: String) {
    fixturesRoot.resolve(COMMON_FIXTURE_NAME)
        .copyToRecursively(projectDirectory, followLinks = false)
    fixturesRoot.resolve(fixtureName)
        .copyToRecursively(projectDirectory, followLinks = false,
            overwrite = true) // patches the common fixture
}
```

Custom copying action

To define your own custom logic for copying, use the overload that has `copyAction` as an additional argument. By using `copyAction` you can provide a lambda function, for example, with your preferred actions:

```
sourceRoot.copyToRecursively(destinationRoot, followLinks = false) { source, target →
    if (source.name.startsWith(".")) {
        CopyActionResult.SKIP_SUBTREE
    } else {
        source.copyToIgnoringExistingDirectory(target, followLinks = false)
        CopyActionResult.CONTINUE
    }
}
```

For more information on these extension functions, see our API reference.

Java Optionals extension functions

The extension functions that were introduced in Kotlin 1.7.0 are now Stable. These functions simplify working with Optional classes in Java. They can be used to unwrap and convert `Optional` objects on the JVM, and to make working with Java APIs more concise. For more information, see What's new in Kotlin 1.7.0.

Improved kotlin-reflect performance

Taking advantage of the fact that `kotlin-reflect` is now compiled with JVM target 1.8, we migrated our internal cache mechanism to Java's `ClassValue`. Previously we only cached `KClass`, but we now also cache `KType` and `KDeclarationContainer`. These changes have led to significant performance improvements when invoking `typeOf()`.

Documentation updates

The Kotlin documentation has received some notable changes:

Revamped and new pages

- Gradle overview – learn how to configure and build a Kotlin project with the Gradle build system, available compiler options, compilation, and caches in the Kotlin Gradle plugin.
- Nullability in Java and Kotlin – see the differences between Java's and Kotlin's approaches to handling possibly nullable variables.
- Lincheck guide – learn how to set up and use the Lincheck framework for testing concurrent algorithms on the JVM.

New and updated tutorials

- Get started with Gradle and Kotlin/JVM – create a console application using IntelliJ IDEA and Gradle.
- Create a multiplatform app using Ktor and SQLDelight – create a mobile application for iOS and Android using Kotlin Multiplatform Mobile.
- Get started with Kotlin Multiplatform – learn about cross-platform mobile development with Kotlin and create an app that works on both Android and iOS.

Install Kotlin 1.8.0

IntelliJ IDEA 2021.3, 2022.1, and 2022.2 automatically suggest updating the Kotlin plugin to version 1.8.0. IntelliJ IDEA 2022.3 will have the 1.8.0 version of the Kotlin plugin bundled in an upcoming minor update.

> To migrate existing projects to Kotlin 1.8.0 in IntelliJ IDEA 2022.3, change the Kotlin version to `1.8.0` and reimport your Gradle or Maven project.

For Android Studio Electric Eel (221) and Flamingo (222), version 1.8.0 of the Kotlin plugin will be delivered with the upcoming Android Studios updates. The new command-line compiler is available for download on the GitHub release page.

Compatibility guide for Kotlin 1.8.0

Kotlin 1.8.0 is a feature release and can, therefore, bring changes that are incompatible with your code written for earlier versions of the language. Find the detailed list of these changes in the Compatibility guide for Kotlin 1.8.0.

Compatibility guide for Kotlin 1.8.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.7 to Kotlin 1.8.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Prohibit the delegation of super calls to an abstract superclass member

Issues: KT-45508, KT-49017, KT-38078

Component: Core language

Incompatible change type: source

Short summary: Kotlin will report a compile error when an explicit or implicit super call is delegated to an *abstract* member of the superclass, even if there's a default implementation in a super interface

Deprecation cycle:

- 1.5.20: introduce a warning when non-abstract classes that do not override all abstract members are used
- 1.7.0: report a warning if a super call, in fact, accesses an abstract member from a superclass
- 1.7.0: report an error in all affected cases if the `-Xjvm-default=all` or `-Xjvm-default=all-compatibility` compatibility modes are enabled; report an error in the progressive mode
- 1.8.0: report an error in cases of declaring a concrete class with a non-overridden abstract method from the superclass, and super calls of `Any` methods are overridden as abstract in the superclass
- 1.9.0: report an error in all affected cases, including explicit super calls to an abstract method from the super class

Deprecate confusing grammar in when-with-subject

Issue: KT-48385

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 deprecated several confusing grammar constructs in `when` condition expressions

Deprecation cycle:

- 1.6.20: introduce a deprecation warning on the affected expressions
- 1.8.0: raise this warning to an error, `-XXLanguage:-ProhibitConfusingSyntaxInWhenBranches` can be used to temporarily revert to the pre-1.8 behavior
- >= 1.9: repurpose some deprecated constructs for new language features

Prevent implicit coercions between different numeric types

Issue: KT-48645

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin will avoid converting numeric values automatically to a primitive numeric type where only a downcast to that type is needed semantically

Deprecation cycle:

- < 1.5.30: the old behavior in all affected cases
- 1.5.30: fix the downcast behavior in generated property delegate accessors, `-Xuse-old-backend` can be used to temporarily revert to the pre-1.5.30 fix behavior
- >= 1.9: fix the downcast behavior in other affected cases

Make private constructors of sealed classes really private

Issue: KT-44866

Component: Core language

Incompatible change type: source

Short summary: after relaxing restrictions on where the inheritors of sealed classes could be declared in the project structure, the default visibility of sealed class constructors became protected. However, until 1.8, Kotlin still allowed calling explicitly declared private constructors of sealed classes outside those classes' scopes

Deprecation cycle:

- 1.6.20: report a warning (or an error in the progressive mode) when a private constructor of a sealed class is called outside that class
- 1.8.0: use default visibility rules for private constructors (a call to a private constructor can be resolved only if this call is inside the corresponding class), the old behavior can be brought back temporarily by specifying the `-XXLanguage:-UseConsistentRulesForPrivateConstructorsOfSealedClasses` compiler argument

Prohibit using operator == on incompatible numeric types in builder inference context

Issue: KT-45508

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.8 will prohibit using the operator `==` on incompatible numeric types, for example, `Int` and `Long`, in scopes of builder inference lambda functions, the same way as it currently does in other contexts

Deprecation cycle:

- 1.6.20: report a warning (or an error in the progressive mode) when the operator `==` is used on incompatible numeric types
- 1.8.0: raise the warning to an error, `-XXLanguage:-ProperEqualityChecksInBuilderInferenceCalls` can be used to temporarily revert to the pre-1.8 behavior

Prohibit if without else and non-exhaustive when in right hand side of elvis operator

Issue: KT-44705

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.8 will prohibit using a non-exhaustive `when` or the `if` expression without an `else` branch on the right hand side of the Elvis operator (`?:`). Previously, it was allowed if the Elvis operator's result was not used as an expression

Deprecation cycle:

- 1.6.20: report a warning (or an error in the progressive mode) on such non-exhaustive if and when expressions
- 1.8.0: raise this warning to an error, `-XXLanguage:-ProhibitNonExhaustiveIfInRhsOfElvis` can be used to temporarily revert to the pre-1.8 behavior

Prohibit upper bound violation in a generic type alias usage (one type parameter used in several type arguments of the aliased type)

Issues: KT-29168

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.8 will prohibit using a type alias with type arguments that violate the upper bound restrictions of the corresponding type parameters of the aliased type in case when one typealias type parameter is used in several type arguments of the aliased type, for example, `typealias Alias<T> = Base<T, T>`

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) on usages of a type alias with type arguments violating upper bound constraints of the corresponding type parameters of the aliased type
- 1.8.0: raise this warning to an error, `-XXLanguage:-ReportMissingUpperBoundsViolatedErrorOnAbbreviationAtSupertypes` can be used to temporarily revert to the pre-1.8 behavior

Prohibit upper bound violation in a generic type alias usage (a type parameter used in a generic type argument of a type argument of the aliased type)

Issue: KT-54066

Component: Core language

Incompatible change type: source

Short summary: Kotlin will prohibit using a type alias with type arguments that violate the upper bound restrictions of the corresponding type parameters of the aliased type in case when the typealias type parameter is used as a generic type argument of a type argument of the aliased type, for example, `typealias Alias<T> = Base<List<T>>`

Deprecation cycle:

- 1.8.0: report a warning when a generic typealias usage has type arguments violating upper bound constraints of the corresponding type parameters of the aliased type
- >=1.10: raise the warning to an error

Prohibit using a type parameter declared for an extension property inside delegate

Issue: KT-24643

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.8 will prohibit delegating extension properties on a generic type to generic types that use the type parameter of the receiver in an unsafe way

Deprecation cycle:

- 1.6.0: report a warning (or an error in the progressive mode) when delegating an extension property to a type that uses type parameters inferred from the delegated property's type arguments in a particular way
- 1.8.0: raise the warning to an error, `-XXLanguage:-ForbidUsingExtensionPropertyTypeParameterInDelegate` can be used to temporarily revert to the pre-1.8 behavior

Forbid @Synchronized annotation on suspend functions

Issue: KT-48516

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.8 will prohibit placing the `@Synchronized` annotation on suspend functions because a suspending call should not be allowed to happen inside a synchronized block

Deprecation cycle:

- 1.6.0: report a warning on suspend functions annotated with the `@Synchronized` annotation, the warning is reported as an error in the progressive mode
- 1.8.0: raise the warning to an error, `-XXLanguage:-SynchronizedSuspendError` can be used to temporarily revert to the pre-1.8 behavior

Prohibit using spread operator for passing arguments to non-vararg parameters

Issue: KT-48162

Component: Core language

Incompatible change type: source

Short summary: Kotlin allowed passing arrays with the spread operator (`*`) to non-vararg array parameters in certain conditions. Since Kotlin 1.8, this will be prohibited

Deprecation cycle:

- 1.6.0: report a warning (or an error in the progressive mode) on using the spread operator where a non-vararg array parameter is expected
- 1.8.0: raise the warning to an error, `-XXLanguage:-ReportNonVarargSpreadOnGenericCalls` can be used to temporarily revert to the pre-1.8 behavior

Prohibit null-safety violation in lambdas passed to functions overloaded by lambda return type

Issue: KT-49658

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.8 will prohibit returning `null` from lambdas passed to functions overloaded by those lambdas' return types when overloads don't allow a nullable return type. Previously, it was allowed when `null` was returned from one of the branches of the `when` operator

Deprecation cycle:

- 1.6.20: report a type mismatch warning (or an error in the progressive mode)
- 1.8.0: raise the warning to an error, `-XXLanguage:-DontLoseDiagnosticsDuringOverloadResolutionByReturnType` can be used to temporarily revert to the pre-1.8 behavior

Keep nullability when approximating local types in public signatures

Issue: KT-53982

Component: Core language

Incompatible change type: source, binary

Short summary: when a local or anonymous type is returned from an expression-body function without an explicitly specified return type, Kotlin compiler infers (or approximates) the return type using the known supertype of that type. During this, the compiler can infer a non-nullable type where the null value could in fact be returned

Deprecation cycle:

- 1.8.0: approximate flexible types by flexible supertypes
- 1.8.0: report a warning when a declaration is inferred to have a non-nullable type that should be nullable, prompting users to specify the type explicitly
- 1.9.0: approximate nullable types by nullable supertypes, `-XXLanguage:-KeepNullabilityWhenApproximatingLocalType` can be used to temporarily revert to the pre-1.9 behavior

Do not propagate deprecation through overrides

Issue: KT-47902

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will no longer propagate deprecation from a deprecated member in the superclass to its overriding member in the subclass, thus providing an explicit mechanism for deprecating a member of the superclass while leaving it non-deprecated in the subclass

Deprecation cycle:

- 1.6.20: reporting a warning with the message of the future behavior change and a prompt to either suppress this warning or explicitly write a `@Deprecated` annotation on an override of a deprecated member
- 1.9.0: stop propagating deprecation status to the overridden members. This change also takes effect immediately in the progressive mode

Prohibit implicit inferring a type variable into an upper bound in the builder inference context

Issue: KT-47986

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit inferring a type variable into the corresponding type parameter's upper bound in the absence of any use-site type information in the scope of builder inference lambda functions, the same way as it does currently in other contexts

Deprecation cycle:

- 1.7.20: report a warning (or an error in the progressive mode) when a type parameter is inferred into declared upper bounds in the absence of use-site type information
- 1.9.0: raise the warning to an error, `-XXLanguage:-ForbidInferringPostponedTypeVariableIntoDeclaredUpperBound` can be used to temporarily revert to the pre-1.9 behavior

Prohibit using collection literals in annotation classes anywhere except their parameters declaration

Issue: KT-39041

Component: Core language

Incompatible change type: source

Short summary: Kotlin allows using collection literals in a restricted way - for passing arrays to parameters of annotation classes or specifying default values for these parameters. However besides that, Kotlin allowed using collections literals anywhere else inside an annotation class, for example, in its nested object. Kotlin 1.9 will prohibit using collection literals in annotation classes anywhere except their parameters' default values.

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) on array literals in nested objects in annotation classes
- 1.9.0: raise the warning to an error

Prohibit forward referencing of parameters with default values in default value expressions

Issue: KT-25694

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit forward referencing of parameters with default values in default value expressions of other parameters. This ensures that by the time the parameter is accessed in a default value expression, it would already have a value either passed to the function or initialized by its own default value expression

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) when a parameter with default value is references in default value of another parameter that comes before it
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitIllegalValueParameterUsageInDefaultArguments` can be used to temporarily revert to the pre-1.9 behavior

Prohibit extension calls on inline functional parameters

Issue: KT-52502

Component: Core language

Incompatible change type: source

Short summary: while Kotlin allowed passing an inline functional parameter to another inline function as a receiver, it always resulted in compiler exceptions when compiling such code. Kotlin 1.9 will prohibit this, thus reporting an error instead of crashing the compiler

Deprecation cycle:

- 1.7.20: report a warning (or an error in the progressive mode) for inline extension calls on inline functional parameters
- 1.9.0: raise the warning to an error

Prohibit calls to infix functions named suspend with an anonymous function argument

Issue: KT-49264

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will no longer allow calling infix functions named `suspend` that have a single argument of a functional type passed as an anonymous function literal

Deprecation cycle:

- 1.7.20: report a warning on suspend infix calls with an anonymous function literal
- 1.9.0: raise the warning to an error, `-XXLanguage:-ModifierNonBuiltinSuspendFunError` can be used to temporarily revert to the pre-1.9 behavior
- >=1.10: Change how the `suspend fun` token sequence is interpreted by the parser

Prohibit using captured type parameters in inner classes against their variance

Issue: KT-50947

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit using type parameters of an outer class having `in` or `out` variance in an inner class of that class in positions violating that type parameters' declared variance

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) when an outer class' type parameter usage position violates the variance rules of that parameter
- 1.9.0: raise the warning to an error, `-XXLanguage:-ReportTypeVarianceConflictOnQualifierArguments` can be used to temporarily revert to the pre-1.9 behavior

Prohibit recursive call of a function without explicit return type in compound assignment operators

Issue: KT-48546

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit calling a function without explicitly specified return type in an argument of a compound assignment operator inside that function's body, as it currently does in other expressions inside the body of that function

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) when a function without explicitly specified return type is called recursively in that function's body in a compound assignment operator argument
- 1.9.0: raise the warning to an error

Prohibit unsound calls with expected @NotNull T and given Kotlin generic parameter with nullable bound

Issue: KT-36770

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit method calls where a value of a potentially nullable generic type is passed for a `@NotNull`-annotated parameter of a Java method

Deprecation cycle:

- 1.5.20: report a warning when an unconstrained generic type parameter is passed where a non-nullable type is expected
- 1.9.0: report a type mismatch error instead of the warning above, `-XXLanguage:-ProhibitUsingNullableTypeParameterAgainstNotNullAnnotated` can be used to temporarily revert to the pre-1.8 behavior

Prohibit access to members of a companion of an enum class from entry initializers of this enum

Issue: KT-49110

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.9 will prohibit all kinds of access to the companion object of an enum from an enum entry initializer

Deprecation cycle:

- 1.6.20: report a warning (or an error in the progressive mode) on such companion member access
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitAccessToEnumCompanionMembersInEnumConstructorCall` can be used to temporarily revert to the pre-1.8 behavior

Deprecate and remove Enum.declaringClass synthetic property

Issue: KT-49653

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin allowed using the synthetic property `declaringClass` on `Enum` values produced from the method `getDeclaringClass()` of the underlying Java class `java.lang.Enum` even though this method is not available for Kotlin `Enum` type. Kotlin 1.9 will prohibit using this property, proposing to migrate to the extension property `declaringJavaClass` instead

Deprecation cycle:

- 1.7.0: report a warning (or an error in the progressive mode) on `declaringClass` property usages, propose the migration to `declaringJavaClass` extension
- 1.9.0: raise the warning to an error, `-XXLanguage:-ProhibitEnumDeclaringClass` can be used to temporarily revert to the pre-1.9 behavior
- >=1.10: remove `declaringClass` synthetic property

Deprecate the enable and the compatibility modes of the compiler option -Xjvm-default

Issue: KT-46329

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.6.20 warns about the usage of the `enable` and `compatibility` modes of the `-Xjvm-default` compiler option

Deprecation cycle:

- 1.6.20: introduce a warning on the `enable` and `compatibility` modes of the `-Xjvm-default` compiler option
- >= 1.9: raise this warning to an error

Standard library

Warn about potential overload resolution change when Range/Progression starts implementing Collection

Issue: KT-49276

Component: Core language / kotlin-stdlib

Incompatible change type: source

Short summary: it is planned to implement the `Collection` interface in the standard progressions and concrete ranges inherited from them in Kotlin 1.9. This could make a different overload selected in the overload resolution if there are two overloads of some method, one accepting an element and another accepting a collection. Kotlin will make this situation visible by reporting a warning or an error when such overloaded method is called with a range or progression argument

Deprecation cycle:

- 1.6.20: report a warning when an overloaded method is called with the standard progression or its range inheritor as an argument if implementing the `Collection` interface by this progression/range leads to another overload being selected in this call in future
- 1.8.0: raise this warning to an error
- 1.9.0: stop reporting the error, implement `Collection` interface in progressions thus changing the overload resolution result in the affected cases

Migrate declarations from kotlin.dom and kotlin.browser packages to kotlinx.*

Issue: KT-39330

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: declarations from the `kotlin.dom` and `kotlin.browser` packages are moved to the corresponding `kotlinx.*` packages to prepare for extracting them from stdlib

Deprecation cycle:

- 1.4.0: introduce the replacement API in `kotlinx.dom` and `kotlinx.browser` packages
- 1.4.0: deprecate the API in `kotlin.dom` and `kotlin.browser` packages and propose the new API above as a replacement
- 1.6.0: raise the deprecation level to an error
- 1.8.20: remove the deprecated functions from stdlib for JS-IR target
- >= 1.9: move the API in kotlinx.* packages to a separate library

Deprecate some JS-only API

Issue: KT-48587

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: a number of JS-only functions in stdlib are deprecated for removal. They include: `String.concat(String)`, `String.match(regex: String)`, `String.matches(regex: String)`, and the `sort` functions on arrays taking a comparison function, for example, `Array<out T>.sort(comparison: (a: T, b: T) -> Int)`

Deprecation cycle:

- 1.6.0: deprecate the affected functions with a warning
- 1.9.0: raise the deprecation level to an error
- >=1.10.0: remove the deprecated functions from the public API

Tools

Raise deprecation level of classpath property of KotlinCompile task

Issue: KT-51679

Component: Gradle

Incompatible change type: source

Short summary: the `classpath` property of the `KotlinCompile` task is deprecated

Deprecation cycle:

- 1.7.0: the `classpath` property is deprecated
- 1.8.0: raise the deprecation level to an error
- >=1.9.0: remove the deprecated functions from the public API

Remove kapt.use.worker.api Gradle property

Issue: KT-48827

Component: Gradle

Incompatible change type: behavioral

Short summary: remove the `kapt.use.worker.api` property that allowed to run kapt via Gradle Workers API (default: true)

Deprecation cycle:

- 1.6.20: raise the deprecation level to a warning
- 1.8.0: remove this property

Remove kotlin.compiler.execution.strategy system property

Issue: KT-51831

Component: Gradle

Incompatible change type: behavioral

Short summary: remove the `kotlin.compiler.execution.strategy` system property used to choose a compiler execution strategy. Use the Gradle property `kotlin.compiler.execution.strategy` or the compile task property `compilerExecutionStrategy` instead

Deprecation cycle:

- 1.7.0: raise the deprecation level to a warning
- 1.8.0: remove the property

Changes in compiler options

Issues: KT-27301, KT-48532

Component: Gradle

Incompatible change type: source, binary

Short summary: this change might affect Gradle plugins authors. In `kotlin-gradle-plugin`, there are additional generic parameters to some internal types (you should add generic types or `*`). `KotlinNativeLink` task does not inherit the `AbstractKotlinNativeCompile` task anymore. `KotlinJsCompilerOptions.outputFile` and the related `KotlinJsOptions.outputFile` options are deprecated. Use the `Kotlin2JsCompile.outputFileProperty` task input instead. The `kotlinOptions` task input and the `kotlinOptions{...}` task DSL are in a support mode and will be deprecated in upcoming releases. `compilerOptions` and `kotlinOptions` can not be changed on a task execution phase (see one exception in What's new in Kotlin 1.8). `freeCompilerArgs` returns an immutable `List<String>` – `kotlinOptions.freeCompilerArgs.remove("something")` will fail. The `useOldBackend` property that allowed to use the old JVM backend is removed

Deprecation cycle:

- 1.8.0: `KotlinNativeLink` task does not inherit the `AbstractKotlinNativeCompile`. `KotlinJsCompilerOptions.outputFile` and the related `KotlinJsOptions.outputFile` options are deprecated. The `useOldBackend` property that allowed to use the old JVM backend is removed.

Deprecate kotlin.internal.single.build.metrics.file property

Issue: KT-53357

Component: Gradle

Incompatible change type: source

Short summary: deprecate the `kotlin.internal.single.build.metrics.file` property used to define a single file for build reports. Use the property `kotlin.build.report.single_file` instead with `kotlin.build.report.output=single_file`

Deprecation cycle:

- 1.8.0: raise the deprecation level to a warning >= 1.9: delete the property

What's new in Kotlin 1.7.20

Released: 29 September 2022

The Kotlin 1.7.20 release is out! Here are some highlights from this release:

- The new Kotlin K2 compiler supports `all-open`, SAM with receiver, Lombok, and other compiler plugins
- We introduced the preview of the `..<` operator for creating open-ended ranges
- The new Kotlin/Native memory manager is now enabled by default
- We introduced a new experimental feature for JVM: inline classes with a generic underlying type

You can also find a short overview of the changes in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

Support for Kotlin K2 compiler plugins

The Kotlin team continues to stabilize the K2 compiler. K2 is still in **Alpha** (as announced in the Kotlin 1.7.0 release), but it now supports several compiler plugins. You can follow this YouTrack issue to get updates from the Kotlin team on the new compiler.

Starting with this 1.7.20 release, the Kotlin K2 compiler supports the following plugins:

- `all-open`
- `no-arg`
- SAM with receiver
- Lombok
- AtomicFU
- `jvm-abi-gen`

The Alpha version of the new K2 compiler only works with JVM projects. It doesn't support Kotlin/JS, Kotlin/Native, or other multiplatform projects.

Learn more about the new compiler and its benefits in the following videos:

- The Road to the New Kotlin Compiler
- K2 Compiler: a Top-Down View

How to enable the Kotlin K2 compiler

To enable the Kotlin K2 compiler and test it, use the following compiler option:

```
-Xuse-k2
```

You can specify it in your `build.gradle(.kts)` file:

Kotlin

```
tasks.withType<KotlinCompile> {
    kotlinOptions.useK2 = true
}
```

Groovy

```
compileKotlin {
    kotlinOptions.useK2 = true
}
```

Check out the performance boost on your JVM projects and compare it with the results of the old compiler.

Leave your feedback on the new K2 compiler

We really appreciate your feedback in any form:

- Provide your feedback directly to K2 developers in Kotlin Slack: get an invite and join the #k2-early-adopters channel.
- Report any problems you faced with the new K2 compiler to our issue tracker.
- Enable the **Send usage statistics** option to allow JetBrains collecting anonymous data about K2 usage.

Language

Kotlin 1.7.20 introduces preview versions for new language features, as well as puts restrictions on builder type inference:

- Preview of the ..< operator for creating open-ended ranges
- New data object declarations
- Builder type inference restrictions

Preview of the ..< operator for creating open-ended ranges

The new operator is Experimental, and it has limited support in the IDE.

This release introduces the new `..<` operator. Kotlin has the `..` operator to express a range of values. The new `..<` operator acts like the `until` function and helps you define the open-ended range.

Watch video online.

Our research shows that this new operator does a better job at expressing open-ended ranges and making it clear that the upper bound is not included.

Here is an example of using the `..<` operator in a `when` expression:

```
when (value) {
    in 0.0..<0.25 -> // First quarter
    in 0.25..<0.5 -> // Second quarter
    in 0.5..<0.75 -> // Third quarter
    in 0.75..1.0 ->  // Last quarter  <- Note closed range here
}
```

Standard library API changes

The following new types and operations will be introduced in the `kotlin.ranges` packages in the common Kotlin standard library:

New OpenEndRange<T> interface

The new interface to represent open-ended ranges is very similar to the existing `ClosedRange<T>` interface:

```
interface OpenEndRange<T : Comparable<T>> {
    // Lower bound
    val start: T
    // Upper bound, not included in the range
    val endExclusive: T
    operator fun contains(value: T): Boolean = value ≥ start && value < endExclusive
    fun isEmpty(): Boolean = start ≥ endExclusive
}
```

Implementing OpenEndRange in the existing iterable ranges

When developers need to get a range with an excluded upper bound, they currently use the `until` function to effectively produce a closed iterable range with the same values. To make these ranges acceptable in the new API that takes `OpenEndRange<T>`, we want to implement that interface in the existing iterable ranges: `IntRange`, `LongRange`, `CharRange`, `UIntRange`, and `ULongRange`. So they will simultaneously implement both the `ClosedRange<T>` and `OpenEndRange<T>` interfaces.

```
class IntRange : IntProgression(...), ClosedRange<Int>, OpenEndRange<Int> {
    override val start: Int
    override val endInclusive: Int
    override val endExclusive: Int
}
```

rangeUntil operators for the standard types

The `rangeUntil` operators will be provided for the same types and combinations currently defined by the `rangeTo` operator. We provide them as extension functions for prototype purposes, but for consistency, we plan to make them members later before stabilizing the open-ended ranges API.

How to enable the ..< operator

To use the `..<` operator or to implement that operator convention for your own types, enable the `-language-version 1.8` compiler option.

The new API elements introduced to support the open-ended ranges of the standard types require an opt-in, as usual for an experimental stdlib API: `@OptIn(ExperimentalStdlibApi::class)`. Alternatively, you could use the `-opt-in=kotlin.ExperimentalStdlibApi` compiler option.

Read more about the new operator in this KEEP document.

Improved string representations for singletons and sealed class hierarchies with data objects

Data objects are Experimental, and have limited support in the IDE at the moment.

This release introduces a new type of `object` declaration for you to use: `data object`. Data object behaves conceptually identical to a regular `object` declaration but comes with a clean `toString` representation out of the box.

Watch video online.

```
package org.example
object MyObject
data object MyDataObject

fun main() {
    println(MyObject) // org.example.MyObject@1f32e575
    println(MyDataObject) // MyDataObject
}
```

This makes `data object` declarations perfect for sealed class hierarchies, where you may use them alongside `data class` declarations. In this snippet, declaring `EndOfFile` as a `data object` instead of a plain `object` means that it will get a pretty `toString` without the need to override it manually, maintaining symmetry with the accompanying `data class` definitions:

```
sealed class ReadResult {
    data class Number(val value: Int) : ReadResult()
    data class Text(val value: String) : ReadResult()
    data object EndOfFile : ReadResult()
}

fun main() {
    println(ReadResult.Number(1)) // Number(value=1)
    println(ReadResult.Text("Foo")) // Text(value=Foo)
    println(ReadResult.EndOfFile) // EndOfFile
}
```

How to enable data objects

To use data object declarations in your code, enable the `-language-version 1.9` compiler option. In a Gradle project, you can do so by adding the following to your `build.gradle(.kts)`:

Kotlin

```
tasks.withType<org.jetbrains.kotlin.gradle.tasks.KotlinCompile>().configureEach {
    // ...
    kotlinOptions.languageVersion = "1.9"
}
```

Groovy

```
compileKotlin {
    // ...
    kotlinOptions.languageVersion = '1.9'
}
```

Read more about data objects, and share your feedback on their implementation in the respective KEEP document.

New builder type inference restrictions

Kotlin 1.7.20 places some major restrictions on the use of builder type inference that could affect your code. These restrictions apply to code containing builder lambda functions, where it's impossible to derive the parameter without analyzing the lambda itself. The parameter is used as an argument. Now, the compiler will always show an error for such code and ask you to specify the type explicitly.

This is a breaking change, but our research shows that these cases are very rare, and the restrictions shouldn't affect your code. If they do, consider the following cases:

- Builder inference with extension that hides members.

  If your code contains an extension function with the same name that will be used during the builder inference, the compiler will show you an error:

  ```
  class Data {
      fun doSmth() {} // 1
  }

  fun <T> T.doSmth() {} // 2

  fun test() {
      buildList {
          this.add(Data())
          this.get(0).doSmth() // Resolves to 2 and leads to error
      }
  }
  ```

  To fix the code, you should specify the type explicitly:

  ```
  class Data {
      fun doSmth() {} // 1
  }

  fun <T> T.doSmth() {} // 2

  fun test() {
      buildList<Data> { // Type argument!
          this.add(Data())
          this.get(0).doSmth() // Resolves to 1
      }
  }
  ```

- Builder inference with multiple lambdas and the type arguments are not specified explicitly.

  If there are two or more lambda blocks in builder inference, they affect the type. To prevent an error, the compiler requires you to specify the type:

```
fun <T: Any> buildList(
    first: MutableList<T>.() -> Unit,
    second: MutableList<T>.() -> Unit
): List<T> {
    val list = mutableListOf<T>()
    list.first()
    list.second()
    return list
}

fun main() {
    buildList(
        first = { // this: MutableList<String>
            add("")
        },
        second = { // this: MutableList<Int>
            val i: Int = get(0)
            println(i)
        }
    )
}
```

To fix the error, you should specify the type explicitly and fix the type mismatch:

```
fun main() {
    buildList<Int>(
        first = { // this: MutableList<Int>
            add(0)
        },
        second = { // this: MutableList<Int>
            val i: Int = get(0)
            println(i)
        }
    )
}
```

If you haven't found your case mentioned above, file an issue to our team.

See this YouTrack issue for more information about this builder inference update.

Kotlin/JVM

Kotlin 1.7.20 introduces generic inline classes, adds more bytecode optimizations for delegated properties, and supports IR in the kapt stub generating task, making it possible to use all the newest Kotlin features with kapt:

- Generic inline classes
- More optimized cases of delegated properties
- Support for the JVM IR backend in kapt stub generating task

Generic inline classes

Generic inline classes is an Experimental feature. It may be dropped or changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.7.20 allows the underlying type of JVM inline classes to be a type parameter. The compiler maps it to `Any?` or, generally, to the upper bound of the type parameter.

Watch video online.

Consider the following example:

```
@JvmInline
value class UserId<T>(val value: T)

fun compute(s: UserId<String>) {} // Compiler generates fun compute-<hashcode>(s: Any?)
```

The function accepts the inline class as a parameter. The parameter is mapped to the upper bound, not the type argument.

To enable this feature, use the `-language-version 1.8` compiler option.

We would appreciate your feedback on this feature in YouTrack.

More optimized cases of delegated properties

In Kotlin 1.6.0, we optimized the case of delegating to a property by omitting the `$delegate` field and generating immediate access to the referenced property. In 1.7.20, we've implemented this optimization for more cases. The `$delegate` field will now be omitted if a delegate is:

- A named object:

```
object NamedObject {
    operator fun getValue(thisRef: Any?, property: KProperty<*>): String = ...
}

val s: String by NamedObject
```

- A final `val` property with a backing field and a default getter in the same module:

```
val impl: ReadOnlyProperty<Any?, String> = ...

class A {
    val s: String by impl
}
```

- A constant expression, an enum entry, `this`, or `null`. Here's an example of `this`:

```
class A {
    operator fun getValue(thisRef: Any?, property: KProperty<*>) ...

    val s by this
}
```

Learn more about delegated properties.

We would appreciate your feedback on this feature in YouTrack.

Support for the JVM IR backend in kapt stub generating task

> Support for the JVM IR backend in the kapt stub generating task is an Experimental feature. It may be changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes.

Before 1.7.20, the kapt stub generating task used the old backend, and repeatable annotations didn't work with kapt. With Kotlin 1.7.20, we've added support for the JVM IR backend in the kapt stub generating task. This makes it possible to use all the newest Kotlin features with kapt, including repeatable annotations.

To use the IR backend in kapt, add the following option to your `gradle.properties` file:

```
kapt.use.jvm.ir=true
```

We would appreciate your feedback on this feature in YouTrack.

Kotlin/Native

Kotlin 1.7.20 comes with the new Kotlin/Native memory manager enabled by default and gives you the option to customize the `Info.plist` file:

- The new default memory manager
- Customizing the Info.plist file

The new Kotlin/Native memory manager enabled by default

This release brings further stability and performance improvements to the new memory manager, allowing us to promote the new memory manager to Beta.

The previous memory manager complicated writing concurrent and asynchronous code, including issues with implementing the `kotlinx.coroutines` library. This blocked the adoption of Kotlin Multiplatform Mobile because concurrency limitations created problems with sharing Kotlin code between iOS and Android platforms. The new memory manager finally paves the way to promote Kotlin Multiplatform Mobile to Beta.

The new memory manager also supports the compiler cache that makes compilation times comparable to previous releases. For more on the benefits of the new memory manager, see our original blog post for the preview version. You can find more technical details in the documentation.

Configuration and setup

Starting with Kotlin 1.7.20, the new memory manager is the default. Not much additional setup is required.

If you've already turned it on manually, you can remove the `kotlin.native.binary.memoryModel=experimental` option from your `gradle.properties` or `binaryOptions["memoryModel"] = "experimental"` from the `build.gradle(.kts)` file.

If necessary, you can switch back to the legacy memory manager with the `kotlin.native.binary.memoryModel=strict` option in your `gradle.properties`. However, compiler cache support is no longer available for the legacy memory manager, so compilation times might worsen.

Freezing

In the new memory manager, freezing is deprecated. Don't use it unless you need your code to work with the legacy manager (where freezing is still required). This may be helpful for library authors that need to maintain support for the legacy memory manager or developers who want to have a fallback if they encounter issues with the new memory manager.

In such cases, you can temporarily support code for both new and legacy memory managers. To ignore deprecation warnings, do one of the following:

- Annotate usages of the deprecated API with `@OptIn(FreezingIsDeprecated::class)`.
- Apply `languageSettings.optIn("kotlin.native.FreezingIsDeprecated")` to all the Kotlin source sets in Gradle.
- Pass the compiler flag `-opt-in=kotlin.native.FreezingIsDeprecated`.

Calling Kotlin suspending functions from Swift/Objective-C

The new memory manager still restricts calling Kotlin `suspend` functions from Swift and Objective-C from threads other than the main one, but you can lift it with a new Gradle option.

This restriction was originally introduced in the legacy memory manager due to cases where the code dispatched a continuation to be resumed on the original thread. If this thread didn't have a supported event loop, the task would never run, and the coroutine would never be resumed.

In certain cases, this restriction is no longer required, but a check of all the necessary conditions can't be easily implemented. Because of this, we decided to keep it in the new memory manager while introducing an option for you to disable it. For this, add the following option to your `gradle.properties`:

```
kotlin.native.binary.objcExportSuspendFunctionLaunchThreadRestriction=none
```

Do not add this option if you use the `native-mt` version of `kotlinx.coroutines` or other libraries that have the same "dispatch to the original thread" approach.

The Kotlin team is very grateful to Ahmed El-Helw for implementing this option.

Leave your feedback

This is a significant change to our ecosystem. We would appreciate your feedback to help make it even better.

Try the new memory manager on your projects and share feedback in our issue tracker, YouTrack.

Customizing the Info.plist file

When producing a framework, the Kotlin/Native compiler generates the information property list file, `Info.plist`. Previously, it was cumbersome to customize its contents. With Kotlin 1.7.20, you can directly set the following properties:

Property	Binary option
`CFBundleIdentifier`	`bundleId`

Property	Binary option
`CFBundleShortVersionString`	`bundleShortVersionString`
`CFBundleVersion`	`bundleVersion`

To do that, use the corresponding binary option. Pass the `-Xbinary=$option=$value` compiler flag or set the `binaryOption(option, value)` Gradle DSL for the necessary framework.

The Kotlin team is very grateful to Mads Ager for implementing this feature.

Kotlin/JS

Kotlin/JS has received some enhancements that improve the developer experience and boost performance:

- Klib generation is faster in both incremental and clean builds, thanks to efficiency improvements for the loading of dependencies.
- Incremental compilation for development binaries has been reworked, resulting in major improvements in clean build scenarios, faster incremental builds, and stability fixes.
- We've improved `.d.ts` generation for nested objects, sealed classes, and parameters with default values in constructors.

Gradle

The updates for the Kotlin Gradle plugin are focused on compatibility with the new Gradle features and the latest Gradle versions.

Kotlin 1.7.20 contains changes to support Gradle 7.1. Deprecated methods and properties were removed or replaced, reducing the number of deprecation warnings produced by the Kotlin Gradle plugin and unblocking future support for Gradle 8.0.

There are, however, some potentially breaking changes that may need your attention:

Target configuration

- `org.jetbrains.kotlin.gradle.dsl.SingleTargetExtension` now has a generic parameter, `SingleTargetExtension<T : KotlinTarget>`.
- The `kotlin.targets.fromPreset()` convention has been deprecated. Instead, you can still use `kotlin.targets { fromPreset() }`, but we recommend setting up targets explicitly.
- Target accessors auto-generated by Gradle are no longer available inside the `kotlin.targets { }` block. Please use the `findByName("targetName")` method instead.

  Note that such accessors are still available in the case of `kotlin.targets`, for example, `kotlin.targets.linuxX64`.

Source directories configuration

The Kotlin Gradle plugin now adds Kotlin `SourceDirectorySet` as a `kotlin` extension to Java's `SourceSet` group. This makes it possible to configure source directories in the `build.gradle.kts` file similarly to how they are configured in Java, Groovy, and Scala:

```
sourceSets {
    main {
        kotlin {
            java.setSrcDirs(listOf("src/java"))
            kotlin.setSrcDirs(listOf("src/kotlin"))
        }
    }
}
```

You no longer need to use a deprecated Gradle convention and specify the source directories for Kotlin.

Remember that you can also use the `kotlin` extension to access `KotlinSourceSet`:

```
kotlin {
    sourceSets {
        main {
        // ...
        }
    }
}
```

New method for JVM toolchain configuration

This release provides a new `jvmToolchain()` method for enabling the JVM toolchain feature. If you don't need any additional configuration fields, such as `implementation` or `vendor`, you can use this method from the Kotlin extension:

```
kotlin {
    jvmToolchain(17)
}
```

This simplifies the Kotlin project setup process without any additional configuration. Before this release, you could specify the JDK version only in the following way:

```
kotlin {
    jvmToolchain {
        languageVersion.set(JavaLanguageVersion.of(17))
    }
}
```

Standard library

Kotlin 1.7.20 offers new extension functions for the `java.nio.file.Path` class, which allows you to walk through a file tree:

- `walk()` lazily traverses the file tree rooted at the specified path.
- `fileVisitor()` makes it possible to create a `FileVisitor` separately. `FileVisitor` defines actions on directories and files when traversing them.

- `visitFileTree(fileVisitor: FileVisitor, ...)` consumes a ready `FileVisitor` and uses `java.nio.file.Files.walkFileTree()` under the hood.
- `visitFileTree(..., builderAction: FileVisitorBuilder.() -> Unit)` creates a `FileVisitor` with the `builderAction` and calls the `visitFileTree(fileVisitor, ...)` function.
- `FileVisitResult`, return type of `FileVisitor`, has the `CONTINUE` default value that continues the processing of the file.

> The new extension functions for `java.nio.file.Path` are Experimental. They may be changed at any time. Opt-in is required (see details below), and you should use them only for evaluation purposes.

Here are some things you can do with these new extension functions:

- Explicitly create a `FileVisitor` and then use:

```
val cleanVisitor = fileVisitor {
    onPreVisitDirectory { directory, attributes ->
        // Some logic on visiting directories
        FileVisitResult.CONTINUE
    }

    onVisitFile { file, attributes ->
        // Some logic on visiting files
        FileVisitResult.CONTINUE
    }
}

// Some logic may go here

projectDirectory.visitFileTree(cleanVisitor)
```

- Create a `FileVisitor` with the `builderAction` and use it immediately:

```
projectDirectory.visitFileTree {
// Definition of the builderAction:
    onPreVisitDirectory { directory, attributes ->
        // Some logic on visiting directories
        FileVisitResult.CONTINUE
    }

    onVisitFile { file, attributes ->
        // Some logic on visiting files
        FileVisitResult.CONTINUE
    }
}
```

- Traverse a file tree rooted at the specified path with the `walk()` function:

```
@OptIn(kotlin.io.path.ExperimentalPathApi::class)
fun traverseFileTree() {
    val cleanVisitor = fileVisitor {
        onPreVisitDirectory { directory, _ ->
            if (directory.name == "build") {
                directory.toFile().deleteRecursively()
                FileVisitResult.SKIP_SUBTREE
            } else {
                FileVisitResult.CONTINUE
            }
        }

        onVisitFile { file, _ ->
            if (file.extension == "class") {
                file.deleteExisting()
            }
            FileVisitResult.CONTINUE
        }
    }

    val rootDirectory = createTempDirectory("Project")

    rootDirectory.resolve("src").let { srcDirectory ->
        srcDirectory.createDirectory()
        srcDirectory.resolve("A.kt").createFile()
        srcDirectory.resolve("A.class").createFile()
    }

    rootDirectory.resolve("build").let { buildDirectory ->
        buildDirectory.createDirectory()
        buildDirectory.resolve("Project.jar").createFile()
    }

// Use walk function:
    val directoryStructure = rootDirectory.walk(PathWalkOption.INCLUDE_DIRECTORIES)
        .map { it.relativeTo(rootDirectory).toString() }
        .toList().sorted()
    assertPrints(directoryStructure, "[, build, build/Project.jar, src, src/A.class, src/A.kt]")

    rootDirectory.visitFileTree(cleanVisitor)

    val directoryStructureAfterClean = rootDirectory.walk(PathWalkOption.INCLUDE_DIRECTORIES)
        .map { it.relativeTo(rootDirectory).toString() }
        .toList().sorted()
    assertPrints(directoryStructureAfterClean, "[, src, src/A.kt]")
}
```

As is usual for an experimental API, the new extensions require an opt-in: `@OptIn(kotlin.io.path.ExperimentalPathApi::class)` or `@kotlin.io.path.ExperimentalPathApi`. Alternatively, you can use a compiler option: `-opt-in=kotlin.io.path.ExperimentalPathApi`.

We would appreciate your feedback on the `walk()` function and the visit extension functions in YouTrack.

Documentation updates

Since the previous release, the Kotlin documentation has received some notable changes:

Revamped and improved pages

- Basic types overview – learn about the basic types used in Kotlin: numbers, Booleans, characters, strings, arrays, and unsigned integer numbers.
- IDEs for Kotlin development – see the list of IDEs with official Kotlin support and tools that have community-supported plugins.

New articles in the Kotlin Multiplatform journal

- Native and cross-platform app development: how to choose? – check out our overview and advantages of cross-platform app development and the native approach.
- The six best cross-platform app development frameworks – read about the key aspects to help you choose the right framework for your cross-platform project.

New and updated tutorials

- Get started with Kotlin Multiplatform – learn about cross-platform mobile development with Kotlin and create an app that works on both Android and iOS.
- Build a web application with React and Kotlin/JS – create a browser app exploring Kotlin's DSLs and features of a typical React program.

Changes in release documentation

We no longer provide a list of recommended kotlinx libraries for each release. This list included only the versions recommended and tested with Kotlin itself. It didn't take into account that some libraries depend on each other and require a special kotlinx version, which may differ from the recommended Kotlin version.

We're working on finding a way to provide information on how libraries interrelate and depend on each other so that it will be clear which kotlinx library version you should use when you upgrade the Kotlin version in your project.

Install Kotlin 1.7.20

IntelliJ IDEA 2021.3, 2022.1, and 2022.2 automatically suggest updating the Kotlin plugin to 1.7.20.

> For Android Studio Dolphin (213), Electric Eel (221), and Flamingo (222), the Kotlin plugin 1.7.20 will be delivered with upcoming Android Studios updates.

The new command-line compiler is available for download on the GitHub release page.

Compatibility guide for Kotlin 1.7.20

Although Kotlin 1.7.20 is an incremental release, there are still incompatible changes we had to make to limit spread of the issues introduced in Kotlin 1.7.0.

Find the detailed list of such changes in the Compatibility guide for Kotlin 1.7.20.

What's new in Kotlin 1.7.0

Released: 9 June 2022

Kotlin 1.7.0 has been released. It unveils the Alpha version of the new Kotlin/JVM K2 compiler, stabilizes language features, and brings performance improvements for the JVM, JS, and Native platforms.

Here is a list of the major updates in this version:

- The new Kotlin K2 compiler is in Alpha now, and it offers serious performance improvements. It is available only for the JVM, and none of the compiler plugins, including kapt, work with it.
- A new approach to the incremental compilation in Gradle. Incremental compilation is now also supported for changes made inside dependent non-Kotlin modules and is compatible with Gradle.
- We've stabilized opt-in requirement annotations, definitely non-nullable types, and builder inference.
- There's now an underscore operator for type args. You can use it to automatically infer a type of argument when other types are specified.
- This release allows implementation by delegation to an inlined value of an inline class. You can now create lightweight wrappers that do not allocate memory in most cases.

You can also find a short overview of the changes in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

New Kotlin K2 compiler for the JVM in Alpha

This Kotlin release introduces the **Alpha** version of the new Kotlin K2 compiler. The new compiler aims to speed up the development of new language features, unify all of the platforms Kotlin supports, bring performance improvements, and provide an API for compiler extensions.

We've already published some detailed explanations of our new compiler and its benefits:

- The Road to the New Kotlin Compiler
- K2 Compiler: a Top-Down View

It's important to point out that with the Alpha version of the new K2 compiler we were primarily focused on performance improvements, and it only works with JVM projects. It doesn't support Kotlin/JS, Kotlin/Native, or other multi-platform projects, and none of compiler plugins, including kapt, work with it.

Our benchmarks show some outstanding results on our internal projects:

Project	Current Kotlin compiler performance	New K2 Kotlin compiler performance	Performance boost
Kotlin	2.2 KLOC/s	4.8 KLOC/s	~ x2.2
YouTrack	1.8 KLOC/s	4.2 KLOC/s	~ x2.3
IntelliJ IDEA	1.8 KLOC/s	3.9 KLOC/s	~ x2.2
Space	1.2 KLOC/s	2.8 KLOC/s	~ x2.3

The KLOC/s performance numbers stand for the number of thousands of lines of code that the compiler processes per second.

You can check out the performance boost on your JVM projects and compare it with the results of the old compiler. To enable the Kotlin K2 compiler, use the following compiler option:

```
-Xuse-k2
```

Also, the K2 compiler includes a number of bugfixes. Please note that even issues with **State: Open** from this list are in fact fixed in K2.

The next Kotlin releases will improve the stability of the K2 compiler and provide more features, so stay tuned!

If you face any performance issues with the Kotlin K2 compiler, please report them to our issue tracker.

Language

Kotlin 1.7.0 introduces support for implementation by delegation and a new underscore operator for type arguments. It also stabilizes several language features introduced as previews in previous releases:

- Implementation by delegation to inlined value of inline class
- Underscore operator for type arguments
- Stable builder inference
- Stable opt-in requirements
- Stable definitely non-nullable types

Allow implementation by delegation to an inlined value of an inline class

If you want to create a lightweight wrapper for a value or class instance, it's necessary to implement all interface methods by hand. Implementation by delegation solves this issue, but it did not work with inline classes before 1.7.0. This restriction has been removed, so you can now create lightweight wrappers that do not allocate memory in most cases.

```
interface Bar {
    fun foo() = "foo"
}

@JvmInline
value class BarWrapper(val bar: Bar): Bar by bar

fun main() {
    val bw = BarWrapper(object: Bar {})
    println(bw.foo())
}
```

Underscore operator for type arguments

Kotlin 1.7.0 introduces an underscore operator, `_`, for type arguments. You can use it to automatically infer a type argument when other types are specified:

```
abstract class SomeClass<T> {
    abstract fun execute(): T
}

class SomeImplementation : SomeClass<String>() {
    override fun execute(): String = "Test"
}

class OtherImplementation : SomeClass<Int>() {
    override fun execute(): Int = 42
}

object Runner {
    inline fun <reified S: SomeClass<T>, T> run(): T {
        return S::class.java.getDeclaredConstructor().newInstance().execute()
    }
}

fun main() {
    // T is inferred as String because SomeImplementation derives from SomeClass<String>
    val s = Runner.run<SomeImplementation, _>()
    assert(s == "Test")

    // T is inferred as Int because OtherImplementation derives from SomeClass<Int>
    val n = Runner.run<OtherImplementation, _>()
    assert(n == 42)
}
```

You can use the underscore operator in any position in the variables list to infer a type argument.

Stable builder inference

Builder inference is a special kind of type inference that is useful when calling generic builder functions. It helps the compiler infer the type arguments of a call using the type information about other calls inside its lambda argument.

Starting with 1.7.0, builder inference is automatically activated if a regular type inference cannot get enough information about a type without specifying the `-Xenable-builder-inference` compiler option, which was introduced in 1.6.0.

Learn how to write custom generic builders.

Stable opt-in requirements

Opt-in requirements are now Stable and do not require additional compiler configuration.

Before 1.7.0, the opt-in feature itself required the argument `-opt-in=kotlin.RequiresOptIn` to avoid a warning. It no longer requires this; however, you can still use the compiler argument `-opt-in` to opt-in for other annotations, a module.

Stable definitely non-nullable types

In Kotlin 1.7.0, definitely non-nullable types have been promoted to Stable. They provide better interoperability when extending generic Java classes and interfaces.

You can mark a generic type parameter as definitely non-nullable at the use site with the new syntax `T & Any`. The syntactic form comes from the notation for intersection types and is now limited to a type parameter with nullable upper bounds on the left side of `&` and a non-nullable `Any` on the right side:

```
fun <T> elvisLike(x: T, y: T & Any): T & Any = x ?: y

fun main() {
    // OK
    elvisLike<String>("", "").length
    // Error: 'null' cannot be a value of a non-null type
    elvisLike<String>("", null).length

    // OK
    elvisLike<String?>(null, "").length
    // Error: 'null' cannot be a value of a non-null type
    elvisLike<String?>(null, null).length
}
```

Learn more about definitely non-nullable types in this KEEP.

Kotlin/JVM

This release brings performance improvements for the Kotlin/JVM compiler and a new compiler option. Additionally, callable references to functional interface constructors have become Stable. Note that since 1.7.0, the default target version for Kotlin/JVM compilations is `1.8`.

- Compiler performance optimizations
- New compiler option `-Xjdk-release`
- Stable callable references to functional interface constructors
- Removed the JVM target version 1.6

Compiler performance optimizations

Kotlin 1.7.0 introduces performance improvements for the Kotlin/JVM compiler. According to our benchmarks, compilation time has been reduced by 10% on average compared to Kotlin 1.6.0. Projects with lots of usages of inline functions, for example, projects using `kotlinx.html`, will compile faster thanks to the improvements to the bytecode postprocessing.

New compiler option: -Xjdk-release

Kotlin 1.7.0 presents a new compiler option, `-Xjdk-release`. This option is similar to the javac's command-line `--release` option. The `-Xjdk-release` option controls the target bytecode version and limits the API of the JDK in the classpath to the specified Java version. For example, `kotlinc -Xjdk-release=1.8` won't allow referencing `java.lang.Module` even if the JDK in the dependencies is version 9 or higher.

> This option is not guaranteed to be effective for each JDK distribution.

Please leave your feedback on this YouTrack ticket.

Stable callable references to functional interface constructors

Callable references to functional interface constructors are now Stable. Learn how to migrate from an interface with a constructor function to a functional interface using callable references.

Please report any issues you find in YouTrack.

Removed JVM target version 1.6

The default target version for Kotlin/JVM compilations is `1.8`. The `1.6` target has been removed.

Please migrate to JVM target 1.8 or above. Learn how to update the JVM target version for:

- Gradle
- Maven
- The command-line compiler

Kotlin/Native

Kotlin 1.7.0 includes changes to Objective-C and Swift interoperability and stabilizes features that were introduced in previous releases. It also brings performance improvements for the new memory manager along with other updates:

- Performance improvements for the new memory manager
- Unified compiler plugin ABI with JVM and JS IR backends
- Support for standalone Android executables
- Interop with Swift async/await: returning `Void` instead of `KotlinUnit`
- Prohibited undeclared exceptions through Objective-C bridges
- Improved CocoaPods integration
- Overriding of the Kotlin/Native compiler download URL

Performance improvements for the new memory manager

> The new Kotlin/Native memory manager is in Alpha. It may change incompatibly and require manual migration in the future. We would appreciate your feedback in YouTrack.

The new memory manager is still in Alpha, but it is on its way to becoming Stable. This release delivers significant performance improvements for the new memory manager, especially in garbage collection (GC). In particular, concurrent implementation of the sweep phase, introduced in 1.6.20, is now enabled by default. This helps reduce the time the application is paused for GC. The new GC scheduler is better at choosing the GC frequency, especially for larger heaps.

Also, we've specifically optimized debug binaries, ensuring that the proper optimization level and link-time optimizations are used in the implementation code of the memory manager. This helped us improve execution time by roughly 30% for debug binaries on our benchmarks.

Try using the new memory manager in your projects to see how it works, and share your feedback with us in YouTrack.

Unified compiler plugin ABI with JVM and JS IR backends

Starting with Kotlin 1.7.0, the Kotlin Multiplatform Gradle plugin uses the embeddable compiler jar for Kotlin/Native by default. This feature was announced in 1.6.0 as Experimental, and now it's Stable and ready to use.

This improvement is very handy for library authors, as it improves the compiler plugin development experience. Before this release, you had to provide separate artifacts for Kotlin/Native, but now you can use the same compiler plugin artifacts for Native and other supported platforms.

> This feature might require plugin developers to take migration steps for their existing plugins.
>
> Learn how to prepare your plugin for the update in this YouTrack issue.

Support for standalone Android executables

Kotlin 1.7.0 provides full support for generating standard executables for Android Native targets. It was introduced in 1.6.20, and now it's enabled by default.

If you want to roll back to the previous behavior when Kotlin/Native generated shared libraries, use the following setting:

```
binaryOptions["androidProgramType"] = "nativeActivity"
```

Interop with Swift async/await: returning Void instead of KotlinUnit

Kotlin `suspend` functions now return the `Void` type instead of `KotlinUnit` in Swift. This is the result of the improved interop with Swift's `async` / `await`. This feature was introduced in 1.6.20, and this release enables this behavior by default.

You don't need to use the `kotlin.native.binary.unitSuspendFunctionObjCExport=proper` property anymore to return the proper type for such functions.

Prohibited undeclared exceptions through Objective-C bridges

When you call Kotlin code from Swift/Objective-C code (or vice versa) and this code throws an exception, it should be handled by the code where the exception occurred, unless you specifically allowed the forwarding of exceptions between languages with proper conversion (for example, using the `@Throws` annotation).

Previously, Kotlin had another unintended behavior where undeclared exceptions could "leak" from one language to another in some cases. Kotlin 1.7.0 fixes that issue, and now such cases lead to program termination.

So, for example, if you have a `{ throw Exception() }` lambda in Kotlin and call it from Swift, in Kotlin 1.7.0 it will terminate as soon as the exception reaches the Swift code. In previous Kotlin versions, such an exception could leak to the Swift code.

The `@Throws` annotation continues to work as before.

Improved CocoaPods integration

Starting with Kotlin 1.7.0, you no longer need to install the `cocoapods-generate` plugin if you want to integrate CocoaPods in your projects.

Previously, you needed to install both the CocoaPods dependency manager and the `cocoapods-generate` plugin to use CocoaPods, for example, to handle iOS dependencies in Kotlin Multiplatform Mobile projects.

Now setting up the CocoaPods integration is easier, and we've resolved the issue when `cocoapods-generate` couldn't be installed on Ruby 3 and later. Now the newest Ruby versions that work better on Apple M1 are also supported.

See how to set up the initial CocoaPods integration.

Overriding the Kotlin/Native compiler download URL

Starting with Kotlin 1.7.0, you can customize the download URL for the Kotlin/Native compiler. This is useful when external links on the CI are forbidden.

To override the default base URL `https://download.jetbrains.com/kotlin/native/builds`, use the following Gradle property:

```
kotlin.native.distribution.baseDownloadUrl=https://example.com
```

The downloader will append the native version and target OS to this base URL to ensure it downloads the actual compiler distribution.

Kotlin/JS

Kotlin/JS is receiving further improvements to the JS IR compiler backend along with other updates that can make your development experience better:

- Performance improvements for the new IR backend
- Minification for member names when using IR
- Support for older browsers via polyfills in the IR backend
- Dynamically load JavaScript modules from js expressions
- Specify environment variables for JavaScript test runners

Performance improvements for the new IR backend

This release has some major updates that should improve your development experience:

- Incremental compilation performance of Kotlin/JS has been significantly improved. It takes less time to build your JS projects. Incremental rebuilds should now be roughly on par with the legacy backend in many cases now.
- The Kotlin/JS final bundle requires less space, as we have significantly reduced the size of the final artifacts. We've measured up to a 20% reduction in the production bundle size compared to the legacy backend for some large projects.
- Type checking for interfaces has been improved by orders of magnitude.
- Kotlin generates higher-quality JS code

Minification for member names when using IR

The Kotlin/JS IR compiler now uses its internal information about the relationships of your Kotlin classes and functions to apply more efficient minification, shortening the names of functions, properties, and classes. This shrinks the resulting bundled applications.

This type of minification is automatically applied when you build your Kotlin/JS application in production mode and is enabled by default. To disable member name minification, use the `-Xir-minimized-member-names` compiler flag:

```
kotlin {
    js(IR) {
        compilations.all {
            compileKotlinTask.kotlinOptions.freeCompilerArgs += listOf("-Xir-minimized-member-
names=false")
        }
    }
}
```

Support for older browsers via polyfills in the IR backend

The IR compiler backend for Kotlin/JS now includes the same polyfills as the legacy backend. This allows code compiled with the new compiler to run in older browsers that do not support all the methods from ES2015 used by the Kotlin standard library. Only those polyfills actually used by the project are included in the final bundle, which minimizes their potential impact on the bundle size.

This feature is enabled by default when using the IR compiler, and you don't need to configure it.

Dynamically load JavaScript modules from js expressions

When working with the JavaScript modules, most applications use static imports, whose use is covered with the JavaScript module integration. However, Kotlin/JS was missing a mechanism to load JavaScript modules dynamically at runtime in your applications.

Starting with Kotlin 1.7.0, the `import` statement from JavaScript is supported in `js` blocks, allowing you to dynamically bring packages into your application at runtime:

```
val myPackage = js("import('my-package')")
```

Specify environment variables for JavaScript test runners

To tune Node.js package resolution or pass external information to Node.js tests, you can now specify environment variables used by the JavaScript test runners. To define an environment variable, use the `environment()` function with a key-value pair inside the `testTask` block in your build script:

```
kotlin {
    js {
        nodejs {
            testTask {
                environment("key", "value")
            }
        }
    }
}
```

Standard library

In Kotlin 1.7.0, the standard library has received a range of changes and improvements. They introduce new features, stabilize experimental ones, and unify support for named capturing groups for Native, JS, and the JVM:

- min() and max() collection functions return as non-nullable
- Regular expression matching at specific indices
- Extended support of previous language and API versions
- Access to annotations via reflection
- Stable deep recursive functions
- Time marks based on inline classes for default time source
- New experimental extension functions for Java Optionals
- Support for named capturing groups in JS and Native

min() and max() collection functions return as non-nullable

In Kotlin 1.4.0, we renamed the `min()` and `max()` collection functions to `minOrNull()` and `maxOrNull()`. These new names better reflect their behavior – returning null if the receiver collection is empty. It also helped align the functions' behavior with naming conventions used throughout the Kotlin collections API.

The same was true of `minBy()`, `maxBy()`, `minWith()`, and `maxWith()`, which all got their *OrNull() synonyms in Kotlin 1.4.0. Older functions affected by this change were gradually deprecated.

Kotlin 1.7.0 reintroduces the original function names, but with a non-nullable return type. The new `min()`, `max()`, `minBy()`, `maxBy()`, `minWith()`, and `maxWith()` functions now strictly return the collection element or throw an exception.

```
fun main() {
    val numbers = listOf<Int>()
    println(numbers.maxOrNull()) // "null"
    println(numbers.max()) // "Exception in... Collection is empty."
}
```

Regular expression matching at specific indices

The `Regex.matchAt()` and `Regex.matchesAt()` functions, introduced in 1.5.30, are now Stable. They provide a way to check whether a regular expression has an exact match at a particular position in a `String` or `CharSequence`.

`matchesAt()` checks for a match and returns a boolean result:

```
fun main() {
    val releaseText = "Kotlin 1.7.0 is on its way!"
    // regular expression: one digit, dot, one digit, dot, one or more digits
    val versionRegex = "\\d[.]\\d[.]\\d+".toRegex()

    println(versionRegex.matchesAt(releaseText, 0)) // "false"
    println(versionRegex.matchesAt(releaseText, 7)) // "true"
}
```

`matchAt()` returns the match if it's found, or `null` if it isn't:

```
fun main() {
    val releaseText = "Kotlin 1.7.0 is on its way!"
    val versionRegex = "\\d[.]\\d[.]\\d+".toRegex()

    println(versionRegex.matchAt(releaseText, 0)) // "null"
    println(versionRegex.matchAt(releaseText, 7)?.value) // "1.7.0"
}
```

We'd be grateful for your feedback on this YouTrack issue.

Extended support for previous language and API versions

To support library authors developing libraries that are meant to be consumable in a wide range of previous Kotlin versions, and to address the increased frequency of major Kotlin releases, we have extended our support for previous language and API versions.

With Kotlin 1.7.0, we're supporting three previous language and API versions rather than two. This means Kotlin 1.7.0 supports the development of libraries targeting Kotlin versions down to 1.4.0. For more information on backward compatibility, see Compatibility options.

Access to annotations via reflection

The `KAnnotatedElement.findAnnotations()` extension function, which was first introduced in 1.6.0, is now Stable. This reflection function returns all annotations of a given type on an element, including individually applied and repeated annotations.

```
@Repeatable
annotation class Tag(val name: String)

@Tag("First Tag")
@Tag("Second Tag")
fun taggedFunction() {
    println("I'm a tagged function!")
}

fun main() {
    val x = ::taggedFunction
    val foo = x as KAnnotatedElement
    println(foo.findAnnotations<Tag>()) // [@Tag(name=First Tag), @Tag(name=Second Tag)]
}
```

Stable deep recursive functions

Deep recursive functions have been available as an experimental feature since Kotlin 1.4.0, and they are now Stable in Kotlin 1.7.0. Using `DeepRecursiveFunction`, you can define a function that keeps its stack on the heap instead of using the actual call stack. This allows you to run very deep recursive computations. To call a deep recursive function, `invoke` it.

In this example, a deep recursive function is used to calculate the depth of a binary tree recursively. Even though this sample function calls itself recursively 100,000 times, no `StackOverflowError` is thrown:

```
class Tree(val left: Tree?, val right: Tree?)

val calculateDepth = DeepRecursiveFunction<Tree?, Int> { t →
    if (t == null) 0 else maxOf(
        callRecursive(t.left),
        callRecursive(t.right)
    ) + 1
}

fun main() {
    // Generate a tree with a depth of 100_000
    val deepTree = generateSequence(Tree(null, null)) { prev →
        Tree(prev, null)
    }.take(100_000).last()

    println(calculateDepth(deepTree)) // 100000
}
```

Consider using deep recursive functions in your code where your recursion depth exceeds 1000 calls.

Time marks based on inline classes for default time source

Kotlin 1.7.0 improves the performance of time measurement functionality by changing the time marks returned by `TimeSource.Monotonic` into inline value classes. This means that calling functions like `markNow()`, `elapsedNow()`, `measureTime()`, and `measureTimedValue()` doesn't allocate wrapper classes for their `TimeMark` instances. Especially when measuring a piece of code that is part of a hot path, this can help minimize the performance impact of the measurement:

```
@OptIn(ExperimentalTime::class)
fun main() {
    val mark = TimeSource.Monotonic.markNow() // Returned `TimeMark` is inline class
    val elapsedDuration = mark.elapsedNow()
}
```

This optimization is only available if the time source from which the `TimeMark` is obtained is statically known to be `TimeSource.Monotonic`.

New experimental extension functions for Java Optionals

Kotlin 1.7.0 comes with new convenience functions that simplify working with `Optional` classes in Java. These new functions can be used to unwrap and convert optional objects on the JVM and help make working with Java APIs more concise.

The `getOrNull()`, `getOrDefault()`, and `getOrElse()` extension functions allow you to get the value of an `Optional` if it's present. Otherwise, you get `null`, a default value, or a value returned by a function, respectively:

```
val presentOptional = Optional.of("I'm here!")

println(presentOptional.getOrNull())
// "I'm here!"

val absentOptional = Optional.empty<String>()

println(absentOptional.getOrNull())
// null
println(absentOptional.getOrDefault("Nobody here!"))
// "Nobody here!"
println(absentOptional.getOrElse {
    println("Optional was absent!")
    "Default value!"
})
// "Optional was absent!"
// "Default value!"
```

The `toList()`, `toSet()`, and `asSequence()` extension functions convert the value of a present `Optional` to a list, set, or sequence, or return an empty collection otherwise. The `toCollection()` extension function appends the `Optional` value to an already existing destination collection:

```
val presentOptional = Optional.of("I'm here!")
val absentOptional = Optional.empty<String>()
println(presentOptional.toList() + "," + absentOptional.toList())
// ["I'm here!"], []
println(presentOptional.toSet() + "," + absentOptional.toSet())
// ["I'm here!"], []
val myCollection = mutableListOf<String>()
absentOptional.toCollection(myCollection)
println(myCollection)
// []
presentOptional.toCollection(myCollection)
println(myCollection)
// ["I'm here!"]
val list = listOf(presentOptional, absentOptional).flatMap { it.asSequence() }
println(list)
// ["I'm here!"]
```

These extension functions are being introduced as Experimental in Kotlin 1.7.0. You can learn more about `Optional` extensions in this KEEP. As always, we welcome your feedback in the Kotlin issue tracker.

Support for named capturing groups in JS and Native

Starting with Kotlin 1.7.0, named capturing groups are supported not only on the JVM, but on the JS and Native platforms as well.

To give a name to a capturing group, use the (`?<name>group`) syntax in your regular expression. To get the text matched by a group, call the newly introduced `MatchGroupCollection.get()` function and pass the group name.

Retrieve matched group value by name

Consider this example for matching city coordinates. To get a collection of groups matched by the regular expression, use `groups`. Compare retrieving a group's contents by its number (index) and by its name using `value`:

```
fun main() {
    val regex = "\\b(?<city>[A-Za-z\\s]+),\\s(?<state>[A-Z]{2}):\\s(?<areaCode>[0-9]{3})\\b".toRegex()
    val input = "Coordinates: Austin, TX: 123"
    val match = regex.find(input)!!
    println(match.groups["city"]?.value) // "Austin" - by name
    println(match.groups[2]?.value) // "TX" - by number
}
```

Named backreferencing

You can now also use group names when backreferencing groups. Backreferences match the same text that was previously matched by a capturing group. For this, use the `\k<name>` syntax in your regular expression:

```
fun backRef() {
    val regex = "(?<title>\\w+), yes \\k<title>".toRegex()
    val match = regex.find("Do you copy? Sir, yes Sir!")!!
    println(match.value) // "Sir, yes Sir"
    println(match.groups["title"]?.value) // "Sir"
}
```

Named groups in replacement expressions

Named group references can be used with replacement expressions. Consider the `replace()` function that substitutes all occurrences of the specified regular expression in the input with a replacement expression, and the `replaceFirst()` function that swaps the first match only.

Occurrences of `${name}` in the replacement string are substituted with the subsequences corresponding to the captured groups with the specified name. You can compare replacements in group references by name and index:

```
fun dateReplace() {
    val dateRegex = Regex("(?<dd>\\d{2})-(?<mm>\\d{2})-(?<yyyy>\\d{4})")
    val input = "Date of birth: 27-04-2022"
    println(dateRegex.replace(input, "\${yyyy}-\${mm}-\${dd}")) // "Date of birth: 2022-04-27" - by
name
    println(dateRegex.replace(input, "\$3-\$2-\$1")) // "Date of birth: 2022-04-27" - by number
}
```

Gradle

This release introduces new build reports, support for Gradle plugin variants, new statistics in kapt, and a lot more:

- A new approach to incremental compilation
- New build reports for tracking compiler performance
- Changes to the minimum supported versions of Gradle and the Android Gradle plugin
- Support for Gradle plugin variants
- Updates in the Kotlin Gradle plugin API
- Availability of the sam-with-receiver plugin via the plugins API
- Changes in compile tasks
- New statistics of generated files by each annotation processor in kapt

- Deprecation of the kotlin.compiler.execution.strategy system property
- Removal of deprecated options, methods, and plugins

A new approach to incremental compilation

> The new approach to incremental compilation is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below). We encourage you to use it only for evaluation purposes, and we would appreciate your feedback in YouTrack.

In Kotlin 1.7.0, we've reworked incremental compilation for cross-module changes. Now incremental compilation is also supported for changes made inside dependent non-Kotlin modules, and it is compatible with the Gradle build cache. Support for compilation avoidance has also been improved.

We expect you'll see the most significant benefit of the new approach if you use the build cache or frequently make changes in non-Kotlin Gradle modules. Our tests for the Kotlin project on the `kotlin-gradle-plugin` module show an improvement of greater than 80% for the changes after the cache hit.

To try this new approach, set the following option in your `gradle.properties`:

```
kotlin.incremental.useClasspathSnapshot=true
```

> The new approach to incremental compilation is currently available for the JVM backend in the Gradle build system only.

Learn how the new approach to incremental compilation is implemented under the hood in this blog post.

Our plan is to stabilize this technology and add support for other backends (JS, for instance) and build systems. We'd appreciate your reports in YouTrack about any issues or strange behavior you encounter in this compilation scheme. Thank you!

The Kotlin team is very grateful to Ivan Gavrilovic, Hung Nguyen, Cédric Champeau, and other external contributors for their help.

Build reports for Kotlin compiler tasks

> Kotlin build reports are Experimental. They may be dropped or changed at any time. Opt-in is required (see details below). Use them only for evaluation purposes. We appreciate your feedback on them in YouTrack.

Kotlin 1.7.0 introduces build reports that help track compiler performance. Reports contain the durations of different compilation phases and reasons why compilation couldn't be incremental.

Build reports come in handy when you want to investigate issues with compiler tasks, for example:

- When the Gradle build takes too much time and you want to understand the root cause of the poor performance.
- When the compilation time for the same project differs, sometimes taking seconds, sometimes taking minutes.

To enable build reports, declare where to save the build report output in `gradle.properties`:

```
kotlin.build.report.output=file
```

The following values (and their combinations) are available:

- `file` saves build reports in a local file.
- `build_scan` saves build reports in the `custom values` section of the build scan.

  > The Gradle Enterprise plugin limits the number of custom values and their length. In big projects, some values could be lost.

- `http` posts build reports using HTTP(S). The POST method sends metrics in the JSON format. Data may change from version to version. You can see the current version of the sent data in the Kotlin repository.

There are two common cases that analyzing build reports for long-running compilations can help you resolve:

- The build wasn't incremental. Analyze the reasons and fix underlying problems.
- The build was incremental, but took too much time. Try to reorganize source files — split big files, save separate classes in different files, refactor large classes, declare top-level functions in different files, and so on.

Learn more about new build reports in this blog post.

You are welcome to try using build reports in your infrastructure. If you have any feedback, encounter any issues, or want to suggest improvements, please don't hesitate to report them in our issue tracker. Thank you!

Bumping minimum supported versions

Starting with Kotlin 1.7.0, the minimum supported Gradle version is 6.7.1. We had to raise the version to support Gradle plugin variants and the new Gradle API. In the future, we should not have to raise the minimum supported version as often, thanks to the Gradle plugin variants feature.

Also, the minimal supported Android Gradle plugin version is now 3.6.4.

Support for Gradle plugin variants

Gradle 7.0 introduced a new feature for Gradle plugin authors — plugins with variants. This feature makes it easier to add support for new Gradle features while maintaining compatibility for Gradle versions below 7.1. Learn more about variant selection in Gradle.

With Gradle plugin variants, we can ship different Kotlin Gradle plugin variants for different Gradle versions. The goal is to support the base Kotlin compilation in the `main` variant, which corresponds to the oldest supported versions of Gradle. Each variant will have implementations for Gradle features from a corresponding release. The latest variant will support the widest Gradle feature set. With this approach, we can extend support for older Gradle versions with limited functionality.

Currently, there are only two variants of the Kotlin Gradle plugin:

- `main` for Gradle versions 6.7.1–6.9.3
- `gradle70` for Gradle versions 7.0 and higher

In future Kotlin releases, we may add more.

To check which variant your build uses, enable the `--info` log level and find a string in the output starting with `Using Kotlin Gradle plugin`, for example, `Using Kotlin Gradle plugin main variant`.

Here are workarounds for some known issues with variant selection in Gradle:

- ResolutionStrategy in pluginManagement is not working for plugins with multivariants
- Plugin variants are ignored when a plugin is added as the `buildSrc` common dependency

Leave your feedback on this YouTrack ticket.

Updates in the Kotlin Gradle plugin API

The Kotlin Gradle plugin API artifact has received several improvements:

- There are new interfaces for Kotlin/JVM and Kotlin/kapt tasks with user-configurable inputs.
- There is a new `KotlinBasePlugin` interface that all Kotlin plugins inherit from. Use this interface when you want to trigger some configuration action whenever any Kotlin Gradle plugin (JVM, JS, Multiplatform, Native, and other platforms) is applied:

  ```
  project.plugins.withType<org.jetbrains.kotlin.gradle.plugin.KotlinBasePlugin>() {
      // Configure your action here
  }
  ```

  You can leave your feedback about the `KotlinBasePlugin` in this YouTrack ticket.
- We've laid the groundwork for the Android Gradle plugin to configure Kotlin compilation within itself, meaning you won't need to add the Kotlin Android Gradle plugin to your build. Follow Android Gradle Plugin release announcements to learn about the added support and try it out!

The sam-with-receiver plugin is available via the plugins API

The sam-with-receiver compiler plugin is now available via the Gradle plugins DSL:

```
plugins {
    id("org.jetbrains.kotlin.plugin.sam.with.receiver") version "$kotlin_version"
}
```

Changes in compile tasks

Compile tasks have received lots of changes in this release:

- Kotlin compile tasks no longer inherit the Gradle `AbstractCompile` task. They inherit only the `DefaultTask`.
- The `AbstractCompile` task has the `sourceCompatibility` and `targetCompatibility` inputs. Since the `AbstractCompile` task is no longer inherited, these inputs are no longer available in Kotlin users' scripts.
- The `SourceTask.stableSources` input is no longer available, and you should use the `sources` input. `setSource(...)` methods are still available.
- All compile tasks now use the `libraries` input for a list of libraries required for compilation. The `KotlinCompile` task still has the deprecated Kotlin property `classpath`, which will be removed in future releases.
- Compile tasks still implement the `PatternFilterable` interface, which allows the filtering of Kotlin sources. The `sourceFilesExtensions` input was removed in favor of using `PatternFilterable` methods.

- The deprecated `Gradle destinationDir: File` output was replaced with the `destinationDirectory: DirectoryProperty` output.
- The Kotlin/Native `AbstractNativeCompile` task now inherits the `AbstractKotlinCompileTool` base class. This is an initial step toward integrating Kotlin/Native build tools into all the other tools.

Please leave your feedback in this YouTrack ticket.

Statistics of generated files by each annotation processor in kapt

The `kotlin-kapt` Gradle plugin already reports performance statistics for each processor. Starting with Kotlin 1.7.0, it can also report statistics on the number of generated files for each annotation processor.

This is useful to track if there are unused annotation processors as a part of the build. You can use the generated report to find modules that trigger unnecessary annotation processors and update the modules to prevent that.

Enable the statistics in two steps:

- Set the `showProcessorStats` flag to `true` in your `build.gradle.kts`:

```
kapt {
    showProcessorStats = true
}
```

- Set the `kapt.verbose` Gradle property to `true` in your `gradle.properties`:

```
kapt.verbose=true
```

> You can also enable verbose output with the command line option `verbose`.

The statistics will appear in the logs with the `info` level. You'll see the `Annotation processor stats:` line followed by statistics on the execution time of each annotation processor. After these lines, there will be the `Generated files report:` line followed by statistics on the number of generated files for each annotation processor. For example:

```
[INFO] Annotation processor stats:
[INFO] org.mapstruct.ap.MappingProcessor: total: 290 ms, init: 1 ms, 3 round(s): 289 ms, 0 ms, 0 ms
[INFO] Generated files report:
[INFO] org.mapstruct.ap.MappingProcessor: total sources: 2, sources per round: 2, 0, 0
```

Please leave your feedback in this YouTrack ticket.

Deprecation of the kotlin.compiler.execution.strategy system property

Kotlin 1.6.20 introduced new properties for defining a Kotlin compiler execution strategy. In Kotlin 1.7.0, a deprecation cycle has started for the old system property `kotlin.compiler.execution.strategy` in favor of the new properties.

When using the `kotlin.compiler.execution.strategy` system property, you'll receive a warning. This property will be deleted in future releases. To preserve the old behavior, replace the system property with the Gradle property of the same name. You can do this in `gradle.properties`, for example:

```
kotlin.compiler.execution.strategy=out-of-process
```

You can also use the compile task property `compilerExecutionStrategy`. Learn more about this on the Compiler execution strategy page.

Removal of deprecated options, methods, and plugins

Removal of the useExperimentalAnnotation method

In Kotlin 1.7.0, we completed the deprecation cycle for the `useExperimentalAnnotation` Gradle method. Use `optIn()` instead to opt in to using an API in a module.

For example, if your Gradle module is multiplatform:

```
sourceSets {
    all {
        languageSettings.optIn("org.mylibrary.OptInAnnotation")
    }
}
```

Learn more about opt-in requirements in Kotlin.

Removal of deprecated compiler options

We've completed the deprecation cycle for several compiler options:

- The `kotlinOptions.jdkHome` compiler option was deprecated in 1.5.30 and has been removed in the current release. Gradle builds now fail if they contain this option. We encourage you to use Java toolchains, which have been supported since Kotlin 1.5.30.
- The deprecated `noStdlib` compiler option has also been removed. The Gradle plugin uses the `kotlin.stdlib.default.dependency=true` property to control whether the Kotlin standard library is present.

The compiler arguments `-jdkHome` and `-no-stdlib` are still available.

Removal of deprecated plugins

In Kotlin 1.4.0, the `kotlin2js` and `kotlin-dce-plugin` plugins were deprecated, and they have been removed in this release. Instead of `kotlin2js`, use the new `org.jetbrains.kotlin.js` plugin. Dead code elimination (DCE) works when the Kotlin/JS Gradle plugin is properly configured.

In Kotlin 1.6.0, we changed the deprecation level of the `KotlinGradleSubplugin` class to `ERROR`. Developers used this class for writing compiler plugins. In this release, this class has been removed. Use the `KotlinCompilerPluginSupportPlugin` class instead.

The best practice is to use Kotlin plugins with versions 1.7.0 and higher throughout your project.

Removal of the deprecated coroutines DSL option and property

We removed the deprecated `kotlin.experimental.coroutines` Gradle DSL option and the `kotlin.coroutines` property used in `gradle.properties`. Now you can just use *suspending functions* or add the `kotlinx.coroutines` dependency to your build script.

Learn more about coroutines in the Coroutines guide.

Removal of the type cast in the toolchain extension method

Before Kotlin 1.7.0, you had to do the type cast into the `JavaToolchainSpec` class when configuring the Gradle toolchain with Kotlin DSL:

```
kotlin {
    jvmToolchain {
        (this as JavaToolchainSpec).languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)
    }
}
```

Now, you can omit the `(this as JavaToolchainSpec)` part:

```
kotlin {
    jvmToolchain {
        languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)
    }
}
```

Migrating to Kotlin 1.7.0

Install Kotlin 1.7.0

IntelliJ IDEA 2022.1 and Android Studio Chipmunk (212) automatically suggest updating the Kotlin plugin to 1.7.0.

> For IntelliJ IDEA 2022.2, and Android Studio Dolphin (213) or Android Studio Electric Eel (221), the Kotlin plugin 1.7.0 will be delivered with upcoming IntelliJ IDEA and Android Studios updates.

The new command-line compiler is available for download on the GitHub release page.

Migrate existing or start a new project with Kotlin 1.7.0

- To migrate existing projects to Kotlin 1.7.0, change the Kotlin version to `1.7.0` and reimport your Gradle or Maven project. Learn how to update to Kotlin 1.7.0.
- To start a new project with Kotlin 1.7.0, update the Kotlin plugin and run the Project Wizard from **File** | **New** | **Project**.

Compatibility guide for Kotlin 1.7.0

Kotlin 1.7.0 is a feature release and can, therefore, bring changes that are incompatible with your code written for earlier versions of the language. Find the detailed list of such changes in the Compatibility guide for Kotlin 1.7.0.

Compatibility guide for Kotlin 1.7.20

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

Usually incompatible changes happen only in feature releases, but this time we have to introduce two such changes in an incremental release to limit spread of the problems introduced by changes in Kotlin 1.7.

This document summarizes them, providing a reference for migration from Kotlin 1.7.0 and 1.7.10 to Kotlin 1.7.20.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Rollback attempt to fix proper constraints processing

Issue: KT-53813

Component: Core language

Incompatible change type: source

Short summary: Rollback an attempt of fixing issues in type inference constraints processing appeared in 1.7.0 after implementing the change described in KT-52668. The attempt was made in 1.7.10, but it in turn introduced new problems.

Deprecation cycle:

- 1.7.20: Rollback to 1.7.0 behavior

Forbid some builder inference cases to avoid problematic interaction with multiple lambdas and resolution

Issue: KT-53797

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.7 introduced a feature called unrestricted builder inference, so that even the lambdas passed to parameters not annotated with `@BuilderInference` could benefit from the builder inference. However, that could cause several problems if more than one such lambda occurred in a function invocation.

Kotlin 1.7.20 will report an error if more than one lambda function having the corresponding parameter not annotated with `@BuilderInference` requires using builder inference to complete inferring the types in the lambda.

Deprecation cycle:

- 1.7.20: report an error on such lambda functions, `-XXLanguage:+NoBuilderInferenceWithoutAnnotationRestriction` can be used to temporarily revert to the pre-1.7.20 behavior

Compatibility guide for Kotlin 1.7.0

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.6 to Kotlin 1.7.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Make safe call result always nullable

Issue: KT-46860

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.7 will consider the type of safe call result always nullable, even when the receiver of the safe call is non-nullable

Deprecation cycle:

- <1.3: report a warning on an unnecessary safe call on non-nullable receivers
- 1.6.20: warn additionally that the result of an unnecessary safe call will change its type in the next version
- 1.7.0: change the type of safe call result to nullable, `-XXLanguage:-SafeCallsAreAlwaysNullable` can be used to temporarily revert to the pre-1.7 behavior

Prohibit the delegation of super calls to an abstract superclass member

Issues: KT-45508, KT-49017, KT-38078

Component: Core language

Incompatible change type: source

Short summary: Kotlin will report a compile error when an explicit or implicit super call is delegated to an *abstract* member of the superclass, even if there's a default implementation in a super interface

Deprecation cycle:

- 1.5.20: introduce a warning when non-abstract classes that do not override all abstract members are used
- 1.7.0: report an error if a super call, in fact, accesses an abstract member from a superclass
- 1.7.0: report an error if the `-Xjvm-default=all` or `-Xjvm-default=all-compatibility` compatibility modes are enabled; report an error in the progressive mode
- >=1.8.0: report an error in all cases

Prohibit exposing non-public types through public properties declared in a non-public primary constructor

Issue: KT-28078

Component: Core language

Incompatible change type: source

Short summary: Kotlin will prevent declaring public properties having non-public types in a private primary constructor. Accessing such properties from another package could lead to an `IllegalAccessError`

Deprecation cycle:

- 1.3.20: report a warning on a public property that has a non-public type and is declared in a non-public constructor
- 1.6.20: raise this warning to an error in the progressive mode
- 1.7.0: raise this warning to an error

Prohibit access to uninitialized enum entries qualified with the enum name

Issue: KT-41124

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.7 will prohibit access to uninitialized enum entries from the enum static initializer block when these entries are qualified with the enum name

Deprecation cycle:

- 1.7.0: report an error when uninitialized enum entries are accessed from the enum static initializer block

Prohibit computing constant values of complex boolean expressions in when condition branches and conditions of loops

Issue: KT-39883

Component: Core language

Incompatible change type: source

Short summary: Kotlin will no longer make exhaustiveness and control flow assumptions based on constant boolean expressions other than literal `true` and `false`

Deprecation cycle:

- 1.5.30: report a warning when exhaustiveness of `when` or control flow reachability is determined based on a complex constant boolean expression in `when` branch or loop condition
- 1.7.0: raise this warning to an error

Make when statements with enum, sealed, and Boolean subjects exhaustive by default

Issue: KT-47709

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.7 will report an error about the `when` statement with an enum, sealed, or Boolean subject being non-exhaustive

Deprecation cycle:

- 1.6.0: introduce a warning when the `when` statement with an enum, sealed, or Boolean subject is non-exhaustive (error in the progressive mode)
- 1.7.0: raise this warning to an error

Deprecate confusing grammar in when-with-subject

Issue: KT-48385

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 deprecated several confusing grammar constructs in `when` condition expressions

Deprecation cycle:

- 1.6.20: introduce a deprecation warning on the affected expressions
- 1.8.0: raise this warning to an error
- >= 1.8: repurpose some deprecated constructs for new language features

Type nullability enhancement improvements

Issue: KT-48623

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.7 will change how it loads and interprets type nullability annotations in Java code

Deprecation cycle:

- 1.4.30: introduce warnings for cases where more precise type nullability could lead to an error
- 1.7.0: infer more precise nullability of Java types, `-XXLanguage:-TypeEnhancementImprovementsInStrictMode` can be used to temporarily revert to the pre-1.7 behavior

Prevent implicit coercions between different numeric types

Issue: KT-48645

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin will avoid converting numeric values automatically to a primitive numeric type where only a downcast to that type was needed semantically

Deprecation cycle:

- < 1.5.30: the old behavior in all affected cases
- 1.5.30: fix the downcast behavior in generated property delegate accessors, `-Xuse-old-backend` can be used to temporarily revert to the pre-1.5.30 fix behavior
- >= 1.7.20: fix the downcast behavior in other affected cases

Deprecate the enable and the compatibility modes of the compiler option -Xjvm-default

Issue: KT-46329

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.6.20 warns about the usage of `enable` and `compatibility` modes of the `-Xjvm-default` compiler option

Deprecation cycle:

- 1.6.20: introduce a warning on the `enable` and `compatibility` modes of the `-Xjvm-default` compiler option
- >= 1.8.0: raise this warning to an error

Prohibit calls to functions named suspend with a trailing lambda

Issue: KT-22562

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 no longer allows calling user functions named `suspend` that have the single argument of a functional type passed as a trailing lambda

Deprecation cycle:

- 1.3.0: introduce a warning on such function calls
- 1.6.0: raise this warning to an error
- 1.7.0: introduce changes to the language grammar so that `suspend` before `{` is parsed as a keyword

Prohibit smart cast on a base class property if the base class is from another module

Issue: KT-52629

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.7 will no longer allow smart casts on properties of a superclass if that class is located in another module

Deprecation cycle:

- 1.6.0: report a warning on a smart cast on a property declared in the superclass located in another module
- 1.7.0: raise this warning to an error, `-XXLanguage:-ProhibitSmartcastsOnPropertyFromAlienBaseClass` can be used to temporarily revert to the pre-1.7 behavior

Do not neglect meaningful constraints during type inference

Issue: KT-52668

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.4-1.6 neglected some type constraints during type inference due to an incorrect optimization. It could allow writing unsound code, causing `ClassCastException` at runtime. Kotlin 1.7 takes these constraints into account, thus prohibiting the unsound code

Deprecation cycle:

- 1.5.20: report a warning on expressions where a type mismatch would happen if all the type inference constraints were taken into account
- 1.7.0: take all the constraints into account, thus raising this warning to an error, `-XXLanguage:-ProperTypeInferenceConstraintsProcessing` can be used to temporarily revert to the pre-1.7 behavior

Standard library

Gradually change the return type of collection min and max functions to non-nullable

Issue: KT-38854

Component: kotlin-stdlib

Incompatible change type: source

Short summary: the return type of collection `min` and `max` functions will be changed to non-nullable in Kotlin 1.7

Deprecation cycle:

- 1.4.0: introduce `...OrNull` functions as synonyms and deprecate the affected API (see details in the issue)
- 1.5.0: raise the deprecation level of the affected API to an error
- 1.6.0: hide the deprecated functions from the public API
- 1.7.0: reintroduce the affected API but with non-nullable return type

Deprecate floating-point array functions: contains, indexOf, lastIndexOf

Issue: KT-28753

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Kotlin deprecates floating-point array functions `contains`, `indexOf`, `lastIndexOf` that compare values using the IEEE-754 order instead of the total order

Deprecation cycle:

- 1.4.0: deprecate the affected functions with a warning
- 1.6.0: raise the deprecation level to an error
- 1.7.0: hide the deprecated functions from the public API

Migrate declarations from kotlin.dom and kotlin.browser packages to kotlinx.*

Issue: KT-39330

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: declarations from the `kotlin.dom` and `kotlin.browser` packages are moved to the corresponding `kotlinx.*` packages to prepare for extracting them from stdlib

Deprecation cycle:

- 1.4.0: introduce the replacement API in `kotlinx.dom` and `kotlinx.browser` packages
- 1.4.0: deprecate the API in `kotlin.dom` and `kotlin.browser` packages and propose the new API above as a replacement
- 1.6.0: raise the deprecation level to an error
- >= 1.8: remove the deprecated functions from stdlib
- >= 1.8: move the API in kotlinx.* packages to a separate library

Deprecate some JS-only API

Issue: KT-48587

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: a number of JS-only functions in stdlib are deprecated for removal. They include: `String.concat(String)`, `String.match(regex: String)`, `String.matches(regex: String)`, and the `sort` functions on arrays taking a comparison function, for example, `Array<out T>.sort(comparison: (a: T, b: T) -> Int)`

Deprecation cycle:

- 1.6.0: deprecate the affected functions with a warning
- 1.8.0: raise the deprecation level to an error
- 1.9.0: remove the deprecated functions from the public API

Tools

Remove KotlinGradleSubplugin class

Issue: KT-48831

Component: Gradle

Incompatible change type: source

Short summary: remove the `KotlinGradleSubplugin` class. Use the `KotlinCompilerPluginSupportPlugin` class instead

Deprecation cycle:

- 1.6.0: raise the deprecation level to an error
- 1.7.0: remove the deprecated class

Remove useIR compiler option

Issue: KT-48847

Component: Gradle

Incompatible change type: source

Short summary: remove the deprecated and hidden `useIR` compiler option

Deprecation cycle:

- 1.5.0: raise the deprecation level to a warning
- 1.6.0: hide the option
- 1.7.0: remove the deprecated option

Deprecate kapt.use.worker.api Gradle property

Issue: KT-48826

Component: Gradle

Incompatible change type: source

Short summary: deprecate the `kapt.use.worker.api` property that allowed to run kapt via Gradle Workers API (default: true)

Deprecation cycle:

- 1.6.20: raise the deprecation level to a warning
- >= 1.8.0: remove this property

Remove kotlin.experimental.coroutines Gradle DSL option and kotlin.coroutines Gradle property

Issue: KT-50494

Component: Gradle

Incompatible change type: source

Short summary: remove the `kotlin.experimental.coroutines` Gradle DSL option and the `kotlin.coroutines` property

Deprecation cycle:

- 1.6.20: raise the deprecation level to a warning
- 1.7.0: remove the DSL option, its enclosing `experimental` block, and the property

Deprecate useExperimentalAnnotation compiler option

Issue: KT-47763

Component: Gradle

Incompatible change type: source

Short summary: remove the hidden `useExperimentalAnnotation()` Gradle function used to opt in to using an API in a module. `optIn()` function can be used instead

Deprecation cycle:

- 1.6.0: hide the deprecation option
- 1.7.0: remove the deprecated option

Deprecate kotlin.compiler.execution.strategy system property

Issue: KT-51830

Component: Gradle

Incompatible change type: source

Short summary: deprecate the `kotlin.compiler.execution.strategy` system property used to choose a compiler execution strategy. Use the Gradle property `kotlin.compiler.execution.strategy` or the compile task property `compilerExecutionStrategy` instead

Deprecation cycle:

- 1.7.0: raise the deprecation level to a warning
- > 1.7.0: remove the property

Remove kotlinOptions.jdkHome compiler option

Issue: KT-46541

Component: Gradle

Incompatible change type: source

Short summary: remove the `kotlinOptions.jdkHome` compiler option used to include a custom JDK from the specified location into the classpath instead of the default `JAVA_HOME`. Use Java toolchains instead

Deprecation cycle:

- 1.5.30: raise the deprecation level to a warning
- > 1.7.0: remove the option

Remove noStdlib compiler option

Issue: KT-49011

Component: Gradle

Incompatible change type: source

Short summary: remove the `noStdlib` compiler option. The Gradle plugin uses the `kotlin.stdlib.default.dependency=true` property to control whether the Kotlin standard library is present

Deprecation cycle:

- 1.5.0: raise the deprecation level to a warning
- 1.7.0: remove the option

Remove kotlin2js and kotlin-dce-plugin plugins

Issue: KT-48276

Component: Gradle

Incompatible change type: source

Short summary: remove the `kotlin2js` and `kotlin-dce-plugin` plugins. Instead of `kotlin2js`, use the new `org.jetbrains.kotlin.js` plugin. Dead code elimination (DCE) works when the Kotlin/JS Gradle plugin is properly configured

Deprecation cycle:

- 1.4.0: raise the deprecation level to a warning
- 1.7.0: remove the plugins

Changes in compile tasks

Issue: KT-32805

Component: Gradle

Incompatible change type: source

Short summary: Kotlin compile tasks no longer inherit the Gradle `AbstractCompile` task and that's why the `sourceCompatibility` and `targetCompatibility` inputs are no longer available in Kotlin users' scripts. The `SourceTask.stableSources` input is no longer available. The `sourceFilesExtensions` input was removed. The deprecated `Gradle destinationDir: File` output was replaced with the `destinationDirectory: DirectoryProperty` output. The `classpath` property of the `KotlinCompile` task is deprecated

Deprecation cycle:

- 1.7.0: inputs are not available, the output is replaced, the `classpath` property is deprecated

What's new in Kotlin 1.6.20

Released: 4 April 2022

Kotlin 1.6.20 reveals previews of the future language features, makes the hierarchical structure the default for multiplatform projects, and brings evolutionary improvements to other components.

You can also find a short overview of the changes in this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

Language

In Kotlin 1.6.20, you can try two new language features:

- Prototype of context receivers for Kotlin/JVM
- Definitely non-nullable types

Prototype of context receivers for Kotlin/JVM

The feature is a prototype available only for Kotlin/JVM. With `-Xcontext-receivers` enabled, the compiler will produce pre-release binaries that cannot be used in production code. Use context receivers only in your toy projects. We appreciate your feedback in YouTrack.

With Kotlin 1.6.20, you are no longer limited to having one receiver. If you need more, you can make functions, properties, and classes context-dependent (or *contextual*) by adding context receivers to their declaration. A contextual declaration does the following:

- It requires all declared context receivers to be present in a caller's scope as implicit receivers.

- It brings declared context receivers into its body scope as implicit receivers.

```
interface LoggingContext {
    val log: Logger // This context provides a reference to a logger
}

context(LoggingContext)
fun startBusinessOperation() {
    // You can access the log property since LoggingContext is an implicit receiver
    log.info("Operation has started")
}

fun test(loggingContext: LoggingContext) {
    with(loggingContext) {
        // You need to have LoggingContext in a scope as an implicit receiver
        // to call startBusinessOperation()
        startBusinessOperation()
    }
}
```

To enable context receivers in your project, use the `-Xcontext-receivers` compiler option. You can find a detailed description of the feature and its syntax in the KEEP.

Please note that the implementation is a prototype:

- With `-Xcontext-receivers` enabled, the compiler will produce pre-release binaries that cannot be used in production code
- The IDE support for context receivers is minimal for now

Try the feature in your toy projects and share your thoughts and experience with us in this YouTrack issue. If you run into any problems, please file a new issue.

Definitely non-nullable types

> Definitely non-nullable types are in Beta. They are almost stable, but migration steps may be required in the future. We'll do our best to minimize any changes you have to make.

To provide better interoperability when extending generic Java classes and interfaces, Kotlin 1.6.20 allows you to mark a generic type parameter as definitely non-nullable on the use site with the new syntax `T & Any`. The syntactic form comes from a notation of intersection types and is now limited to a type parameter with nullable upper bounds on the left side of `&` and non-nullable `Any` on the right side:

```
fun <T> elvisLike(x: T, y: T & Any): T & Any = x ?: y

fun main() {
    // OK
    elvisLike<String>("", "").length
    // Error: 'null' cannot be a value of a non-null type
    elvisLike<String>("", null).length

    // OK
    elvisLike<String?>(null, "").length
    // Error: 'null' cannot be a value of a non-null type
    elvisLike<String?>(null, null).length
}
```

Set the language version to `1.7` to enable the feature:

Kotlin

```
kotlin {
    sourceSets.all {
        languageSettings.apply {
            languageVersion = "1.7"
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets.all {
        languageSettings {
            languageVersion = '1.7'
        }
    }
}
```

Learn more about definitely non-nullable types in the KEEP.

Kotlin/JVM

Kotlin 1.6.20 introduces:

- Compatibility improvements of default methods in JVM interfaces: new `@JvmDefaultWithCompatibility` annotation for interfaces and compatibility changes in the `-Xjvm-default` modes
- Support for parallel compilation of a single module in the JVM backend
- Support for callable references to functional interface constructors

New @JvmDefaultWithCompatibility annotation for interfaces

Kotlin 1.6.20 introduces the new annotation `@JvmDefaultWithCompatibility`: use it along with the `-Xjvm-default=all` compiler option to create the default method in JVM interface for any non-abstract member in any Kotlin interface.

If there are clients that use your Kotlin interfaces compiled without the `-Xjvm-default=all` option, they may be binary-incompatible with the code compiled with this option. Before Kotlin 1.6.20, to avoid this compatibility issue, the recommended approach was to use the `-Xjvm-default=all-compatibility` mode and also the `@JvmDefaultWithoutCompatibility` annotation for interfaces that didn't need this type of compatibility.

This approach had some disadvantages:

- You could easily forget to add the annotation when a new interface was added.
- Usually there are more interfaces in non-public parts than in the public API, so you end up having this annotation in many places in your code.

Now, you can use the `-Xjvm-default=all` mode and mark interfaces with the `@JvmDefaultWithCompatibility` annotation. This allows you to add this annotation to all interfaces in the public API once, and you won't need to use any annotations for new non-public code.

Leave your feedback about this new annotation in this YouTrack ticket.

Compatibility changes in the -Xjvm-default modes

Kotlin 1.6.20 adds the option to compile modules in the default mode (the `-Xjvm-default=disable` compiler option) against modules compiled with the `-Xjvm-default=all` or `-Xjvm-default=all-compatibility` modes. As before, compilations will also be successful if all modules have the `-Xjvm-default=all` or `-Xjvm-default=all-compatibility` modes. You can leave your feedback in this YouTrack issue.

Kotlin 1.6.20 deprecates the `compatibility` and `enable` modes of the compiler option `-Xjvm-default`. There are changes in other modes' descriptions regarding the compatibility, but the overall logic remains the same. You can check out the updated descriptions.

For more information about default methods in the Java interop, see the interoperability documentation and this blog post.

Support for parallel compilation of a single module in the JVM backend

> Support for parallel compilation of a single module in the JVM backend is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

We are continuing our work to improve the new JVM IR backend compilation time. In Kotlin 1.6.20, we added the experimental JVM IR backend mode to compile all the files in a module in parallel. Parallel compilation can reduce the total compilation time by up to 15%.

Enable the experimental parallel backend mode with the compiler option `-Xbackend-threads`. Use the following arguments for this option:

- `N` is the number of threads you want to use. It should not be greater than your number of CPU cores; otherwise, parallelization stops being effective because of switching context between threads
- `0` to use a separate thread for each CPU core

Gradle can run tasks in parallel, but this type of parallelization doesn't help a lot when a project (or a major part of a project) is just one big task from Gradle's perspective. If you have a very big monolithic module, use parallel compilation to compile more quickly. If your project consists of lots of small modules and has a build parallelized by Gradle, adding another layer of parallelization may hurt performance because of context switching.

> Parallel compilation has some constraints:
>
> - It doesn't work with kapt because kapt disables the IR backend
> - It requires more JVM heap by design. The amount of heap is proportional to the number of threads

Support for callable references to functional interface constructors

> Support for callable references to functional interface constructors is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Support for callable references to functional interface constructors adds a source-compatible way to migrate from an interface with a constructor function to a functional interface.

Consider the following code:

```
interface Printer {
    fun print()
}

fun Printer(block: () -> Unit): Printer = object : Printer { override fun print() = block() }
```

With callable references to functional interface constructors enabled, this code can be replaced with just a functional interface declaration:

```
fun interface Printer {
    fun print()
}
```

Its constructor will be created implicitly, and any code using the `::Printer` function reference will compile. For example:

```
documentsStorage.addPrinter(::Printer)
```

Preserve the binary compatibility by marking the legacy function `Printer` with the `@Deprecated` annotation with `DeprecationLevel.HIDDEN`:

```
@Deprecated(message = "Your message about the deprecation", level = DeprecationLevel.HIDDEN)
fun Printer(...) {...}
```

Use the compiler option `-XXLanguage:+KotlinFunInterfaceConstructorReference` to enable this feature.

Kotlin/Native

Kotlin/Native 1.6.20 marks continued development of its new components. We've taken another step toward consistent experience with Kotlin on other platforms:

- An update on the new memory manager
- Concurrent implementation for the sweep phase in new memory manager
- Instantiation of annotation classes
- Interop with Swift async/await: returning Swift's Void instead of KotlinUnit
- Better stack traces with libbacktrace
- Support for standalone Android executables
- Performance improvements

- Improved error handling during cinterop modules import
- Support for Xcode 13 libraries

An update on the new memory manager

> The new Kotlin/Native memory manager is in Alpha. It may change incompatibly and require manual migration in the future. We would appreciate your feedback on it in YouTrack.

With Kotlin 1.6.20, you can try the Alpha version of the new Kotlin/Native memory manager. It eliminates the differences between the JVM and Native platforms to provide a consistent developer experience in multiplatform projects. For example, you'll have a much easier time creating new cross-platform mobile applications that work on both Android and iOS.

The new Kotlin/Native memory manager lifts restrictions on object-sharing between threads. It also provides leak-free concurrent programming primitives that are safe and don't require any special management or annotations.

The new memory manager will become the default in future versions, so we encourage you to try it now. Check out our blog post to learn more about the new memory manager and explore demo projects, or jump right to the migration instructions to try it yourself.

Try using the new memory manager on your projects to see how it works and share feedback in our issue tracker, YouTrack.

Concurrent implementation for the sweep phase in new memory manager

If you have already switched to our new memory manager, which was announced in Kotlin 1.6, you might notice a huge execution time improvement: our benchmarks show 35% improvement on average. Starting with 1.6.20, there is also a concurrent implementation for the sweep phase available for the new memory manager. This should also improve the performance and decrease the duration of garbage collector pauses.

To enable the feature for the new Kotlin/Native memory manager, pass the following compiler option:

```
-Xgc=cms
```

Feel free to share your feedback on the new memory manager performance in this YouTrack issue.

Instantiation of annotation classes

In Kotlin 1.6.0, instantiation of annotation classes became Stable for Kotlin/JVM and Kotlin/JS. The 1.6.20 version delivers support for Kotlin/Native.

Learn more about instantiation of annotation classes.

Interop with Swift async/await: returning Void instead of KotlinUnit

> Concurrency interoperability with Swift async/await is Experimental. It may be dropped or changed at any time. You should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

We've continued working on the experimental interop with Swift's async/await (available since Swift 5.5). Kotlin 1.6.20 differs from previous versions in the way it works with `suspend` functions with the `Unit` return type.

Previously, such functions were presented in Swift as `async` functions returning `KotlinUnit`. However, the proper return type for them is `Void`, similar to non-suspending functions.

To avoid breaking the existing code, we're introducing a Gradle property that makes the compiler translate `Unit`-returning suspend functions to `async` Swift with the `Void` return type:

```
# gradle.properties
kotlin.native.binary.unitSuspendFunctionObjCExport=proper
```

We plan to make this behavior the default in future Kotlin releases.

Better stack traces with libbacktrace

> Using libbacktrace for resolving source locations is Experimental. It may be dropped or changed at any time. You should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin/Native is now able to produce detailed stack traces with file locations and line numbers for better debugging of `linux*` (except `linuxMips32` and `linuxMipsel32`) and `androidNative*` targets.

This feature uses the libbacktrace library under the hood. Take a look at the following code to see an example of the difference:

```
fun main() = bar()
fun bar() = baz()
inline fun baz() {
    error("")
}
```

- **Before 1.6.20:**

```
Uncaught Kotlin exception: kotlin.IllegalStateException:
   at 0   example.kexe        0x227190       kfun:kotlin.Throwable#<init>(kotlin.String?){} + 96
   at 1   example.kexe        0x221e4c       kfun:kotlin.Exception#<init>(kotlin.String?){} + 92
   at 2   example.kexe        0x221f4c       kfun:kotlin.RuntimeException#<init>(kotlin.String?){} +
92
   at 3   example.kexe        0x22234c       kfun:kotlin.IllegalStateException#<init>(kotlin.String?)
{} + 92
   at 4   example.kexe        0x25d708       kfun:#bar(){} + 104
   at 5   example.kexe        0x25d68c       kfun:#main(){} + 12
```

- **1.6.20 with libbacktrace:**

```
Uncaught Kotlin exception: kotlin.IllegalStateException:
   at 0   example.kexe        0x229550    kfun:kotlin.Throwable#<init>(kotlin.String?){} + 96
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Throwable.kt:24:37)
   at 1   example.kexe        0x22420c    kfun:kotlin.Exception#<init>(kotlin.String?){} + 92
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Exceptions.kt:23:44)
   at 2   example.kexe        0x22430c    kfun:kotlin.RuntimeException#<init>(kotlin.String?){} + 92
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Exceptions.kt:34:44)
   at 3   example.kexe        0x22470c    kfun:kotlin.IllegalStateException#<init>(kotlin.String?){} +
92 (/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Exceptions.kt:70:44)
   at 4   example.kexe        0x25fac8    kfun:#bar(){} + 104 [inlined]
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/libraries/stdlib/src/kotlin/util/Preconditions.kt:143:56)
   at 5   example.kexe        0x25fac8    kfun:#bar(){} + 104 [inlined]
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:4:5)
   at 6   example.kexe        0x25fac8    kfun:#bar(){} + 104
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:2:13)
   at 7   example.kexe        0x25fa4c    kfun:#main(){} + 12
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:1:14)
```

On Apple targets, which already had file locations and line numbers in stack traces, libbacktrace provides more details for inline function calls:

- **Before 1.6.20:**

```
Uncaught Kotlin exception: kotlin.IllegalStateException:
   at 0   example.kexe    0x10a85a8f8    kfun:kotlin.Throwable#<init>(kotlin.String?){} + 88
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Throwable.kt:24:37)
   at 1   example.kexe    0x10a855846    kfun:kotlin.Exception#<init>(kotlin.String?){} + 86
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Exceptions.kt:23:44)
   at 2   example.kexe    0x10a855936    kfun:kotlin.RuntimeException#<init>(kotlin.String?){} + 86
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Exceptions.kt:34:44)
   at 3   example.kexe    0x10a855c86    kfun:kotlin.IllegalStateException#<init>(kotlin.String?){} +
86 (/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Exceptions.kt:70:44)
   at 4   example.kexe    0x10a8489a5    kfun:#bar(){} + 117
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:2:1)
   at 5   example.kexe    0x10a84891c    kfun:#main(){} + 12
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:1:14)
...
```

- **1.6.20 with libbacktrace:**

```
Uncaught Kotlin exception: kotlin.IllegalStateException:
   at 0   example.kexe    0x10669bc88    kfun:kotlin.Throwable#<init>(kotlin.String?){} + 88
(/opt/buildAgent/work/c3a91df21e46e2c8/kotlin/kotlin-
native/runtime/src/main/kotlin/kotlin/Throwable.kt:24:37)

(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:4:5)
   at 6   example.kexe    0x106689d35    kfun:#bar(){} + 117
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:2:13)
   at 7   example.kexe    0x106689cac    kfun:#main(){} + 12
(/private/tmp/backtrace/src/commonMain/kotlin/app.kt:1:14)
...
```

To produce better stack traces with libbacktrace, add the following line to `gradle.properties`:

```
# gradle.properties
kotlin.native.binary.sourceInfoType=libbacktrace
```

Please tell us how debugging Kotlin/Native with libbacktrace works for you in this YouTrack issue.

Support for standalone Android executables

Previously, Android Native executables in Kotlin/Native were not actually executables but shared libraries that you could use as a NativeActivity. Now there's an option to generate standard executables for Android Native targets.

For that, in the `build.gradle(.kts)` part of your project, configure the executable block of your `androidNative` target. Add the following binary option:

```
kotlin {
    androidNativeX64("android") {
        binaries {
            executable {
                binaryOptions["androidProgramType"] = "standalone"
            }
        }
    }
}
```

Note that this feature will become the default in Kotlin 1.7.0. If you want to preserve the current behavior, use the following setting:

```
binaryOptions["androidProgramType"] = "nativeActivity"
```

Thanks to Mattia Iavarone for the implementation!

Performance improvements

We are working hard on Kotlin/Native to speed up the compilation process and improve your developing experience.

Kotlin 1.6.20 brings some performance updates and bug fixes that affect the LLVM IR that Kotlin generates. According to the benchmarks on our internal projects, we achieved the following performance boosts on average:

- 15% reduction in execution time
- 20% reduction in the code size of both release and debug binaries
- 26% reduction in the compilation time of release binaries

These changes also provide a 10% reduction in compilation time for a debug binary on a large internal project.

To achieve this, we've implemented static initialization for some of the compiler-generated synthetic objects, improved the way we structure LLVM IR for every function, and optimized the compiler caches.

Improved error handling during cinterop modules import

This release introduces improved error handling for cases where you import an Objective-C module using the `cinterop` tool (as is typical for CocoaPods pods). Previously, if you got an error while trying to work with an Objective-C module (for instance, when dealing with a compilation error in a header), you received an uninformative error message, such as `fatal error: could not build module $name`. We expanded upon this part of the `cinterop` tool, so you'll get an error message with an extended description.

Support for Xcode 13 libraries

Libraries delivered with Xcode 13 have full support as of this release. Feel free to access them from anywhere in your Kotlin code.

Kotlin Multiplatform

1.6.20 brings the following notable updates to Kotlin Multiplatform:

- Hierarchical structure support is now default for all new multiplatform projects
- Kotlin CocoaPods Gradle plugin received several useful features for CocoaPods integration

Hierarchical structure support for multiplatform projects

Kotlin 1.6.20 comes with hierarchical structure support enabled by default. Since introducing it in Kotlin 1.4.0, we've significantly improved the frontend and made IDE import stable.

Previously, there were two ways to add code in a multiplatform project. The first was to insert it in a platform-specific source set, which is limited to one target and can't be reused by other platforms. The second is to use a common source set shared across all the platforms that are currently supported by Kotlin.

Now you can share source code among several similar native targets that reuse a lot of the common logic and third-party APIs. The technology will provide the correct default dependencies and find the exact API available in the shared code. This eliminates a complex build setup and having to use workarounds to get IDE support for sharing source sets among native targets. It also helps prevent unsafe API usages meant for a different target.

The technology will come in handy for library authors, too, as a hierarchical project structure allows them to publish and consume libraries with common APIs for a subset of targets.

By default, libraries published with the hierarchical project structure are compatible only with hierarchical structure projects.

Better code-sharing in your project

Without hierarchical structure support, there is no straightforward way to share code across *some* but not *all* Kotlin targets. One popular example is sharing code across all iOS targets and having access to iOS-specific dependencies, like Foundation.

Thanks to the hierarchical project structure support, you can now achieve this out of the box. In the new structure, source sets form a hierarchy. You can use platform-specific language features and dependencies available for each target that a given source set compiles to.

For example, consider a typical multiplatform project with two targets — `iosArm64` and `iosX64` for iOS devices and simulators. The Kotlin tooling understands that both targets have the same function and allows you to access that function from the intermediate source set, `iosMain`.

iOS hierarchy example

The Kotlin toolchain provides the correct default dependencies, like Kotlin/Native stdlib or native libraries. Moreover, Kotlin tooling will try its best to find exactly the API surface area available in the shared code. This prevents such cases as, for example, the use of a macOS-specific function in code shared for Windows.

More opportunities for library authors

When a multiplatform library is published, the API of its intermediate source sets is now properly published alongside it, making it available for consumers. Again, the Kotlin toolchain will automatically figure out the API available in the consumer source set while carefully watching out for unsafe usages, like using an API meant for the JVM in JS code. Learn more about sharing code in libraries.

Configuration and setup

Starting with Kotlin 1.6.20, all your new multiplatform projects will have a hierarchical project structure. No additional setup is required.

- If you've already turned it on manually, you can remove the deprecated options from `gradle.properties`:

```
# gradle.properties
kotlin.mpp.enableGranularSourceSetsMetadata=true
kotlin.native.enableDependencyPropagation=false // or 'true', depending on your previous setup
```

- For Kotlin 1.6.20, we recommend using Android Studio 2021.1.1 (Bumblebee) or later to get the best experience.
- You can also opt out. To disable hierarchical structure support, set the following options in `gradle.properties`:

```
# gradle.properties
kotlin.mpp.hierarchicalStructureSupport=false
```

Leave your feedback

This is a significant change to the whole ecosystem. We would appreciate your feedback to help make it even better.

Try it now and report any difficulties you encounter to our issue tracker.

Kotlin CocoaPods Gradle plugin

To simplify CocoaPods integration, Kotlin 1.6.20 delivers the following features:

- The CocoaPods plugin now has tasks that build XCFrameworks with all registered targets and generate the Podspec file. This can be useful when you don't want to integrate with Xcode directly, but you want to build artifacts and deploy them to your local CocoaPods repository.

  Learn more about building XCFrameworks.

- If you use CocoaPods integration in your projects, you're used to specifying the required Pod version for the entire Gradle project. Now you have more options:
  - Specify the Pod version directly in the `cocoapods` block
  - Continue using a Gradle project version

  If none of these properties is configured, you'll get an error.

- You can now configure the CocoaPod name in the `cocoapods` block instead of changing the name of the whole Gradle project.
- The CocoaPods plugin introduces a new `extraSpecAttributes` property, which you can use to configure properties in a Podspec file that were previously hard-coded, like `libraries` or `vendored_frameworks`.

```
kotlin {
    cocoapods {
        version = "1.0"
        name = "MyCocoaPod"
        extraSpecAttributes["social_media_url"] = 'https://twitter.com/kotlin'
        extraSpecAttributes["vendored_frameworks"] = 'CustomFramework.xcframework'
        extraSpecAttributes["libraries"] = 'xml'
    }
}
```

See the full Kotlin CocoaPods Gradle plugin DSL reference.

Kotlin/JS

Kotlin/JS improvements in 1.6.20 mainly affect the IR compiler:

- Incremental compilation for development binaries (IR)
- Lazy initialization of top-level properties by default (IR)
- Separate JS files for project modules by default (IR)
- Char class optimization (IR)
- Export improvements (both IR and legacy backends)
- @AfterTest guarantees for asynchronous tests

Incremental compilation for development binaries with IR compiler

To make Kotlin/JS development with the IR compiler more efficient, we're introducing a new *incremental compilation* mode.

When building **development binaries** with the `compileDevelopmentExecutableKotlinJs` Gradle task in this mode, the compiler caches the results of previous compilations on the module level. It uses the cached compilation results for unchanged source files during subsequent compilations, making them complete more quickly, especially with small changes. Note that this improvement exclusively targets the development process (shortening the edit-build-debug cycle) and doesn't affect the building of production artifacts.

To enable incremental compilation for development binaries, add the following line to the project's `gradle.properties`:

```
# gradle.properties
kotlin.incremental.js.ir=true // false by default
```

In our test projects, the new mode made incremental compilation up to 30% faster. However, the clean build in this mode became slower because of the need to create and populate the caches.

Please tell us what you think of using incremental compilation with your Kotlin/JS projects in this YouTrack issue.

Lazy initialization of top-level properties by default with IR compiler

In Kotlin 1.4.30, we presented a prototype of lazy initialization of top-level properties in the JS IR compiler. By eliminating the need to initialize all properties when the application launches, lazy initialization reduces the startup time. Our measurements showed about a 10% speed-up on a real-life Kotlin/JS application.

Now, having polished and properly tested this mechanism, we're making lazy initialization the default for top-level properties in the IR compiler.

```
// lazy initialization
val a = run {
    val result = // intensive computations
        println(result)
    result
} // run is executed upon the first usage of the variable
```

If for some reason you need to initialize a property eagerly (upon the application start), mark it with the `@EagerInitialization` annotation.

Separate JS files for project modules by default with IR compiler

Previously, the JS IR compiler offered an ability to generate separate `.js` files for project modules. This was an alternative to the default option – a single `.js` file for the whole project. This file might be too large and inconvenient to use, because whenever you want to use a function from your project, you have to include the entire JS file as a dependency. Having multiple files adds flexibility and decreases the size of such dependencies. This feature was available with the `-Xir-per-module` compiler option.

Starting from 1.6.20, the JS IR compiler generates separate `.js` files for project modules by default.

Compiling the project into a single `.js` file is now available with the following Gradle property:

```
# gradle.properties
kotlin.js.ir.output.granularity=whole-program // `per-module` is the default
```

In previous releases, the experimental per-module mode (available via the `-Xir-per-module=true` flag) invoked `main()` functions in each module. This is inconsistent with the regular single `.js` mode. Starting with 1.6.20, the `main()` function will be invoked in the main module only in both cases. If you do need to run some code when a module is loaded, you can use top-level properties annotated with the `@EagerInitialization` annotation. See Lazy initialization of top-level properties by default (IR).

Char class optimization

The `Char` class is now handled by the Kotlin/JS compiler without introducing boxing (similar to inline classes). This speeds up operations on chars in Kotlin/JS code.

Aside from the performance improvement, this changes the way `Char` is exported to JavaScript: it's now translated to `Number`.

Improvements to export and TypeScript declaration generation

Kotlin 1.6.20 is bringing multiple fixes and improvements to the export mechanism (the `@JsExport` annotation), including the generation of TypeScript declarations (`.d.ts`) We've added the ability to export interfaces and enums, and we've fixed the export behavior in some corner cases that were reported to us previously. For more details, see the list of export improvements in YouTrack.

Learn more about using Kotlin code from JavaScript.

@AfterTest guarantees for asynchronous tests

Kotlin 1.6.20 makes `@AfterTest` functions work properly with asynchronous tests on Kotlin/JS. If a test function's return type is statically resolved to `Promise` , the compiler now schedules the execution of the `@AfterTest` function to the corresponding `then()` callback.

Security

Kotlin 1.6.20 introduces a couple of features to improve the security of your code:

- Using relative paths in klibs
- Persisting yarn.lock for Kotlin/JS Gradle projects
- Installation of npm dependencies with `--ignore-scripts` by default

Using relative paths in klibs

A library in `klib` format contains a serialized IR representation of source files, which also includes their paths for generating proper debug information. Before Kotlin 1.6.20, stored file paths were absolute. Since the library author may not want to share absolute paths, the 1.6.20 version comes with an alternative option.

If you are publishing a `klib` and want to use only relative paths of source files in the artifact, you can now pass the `-Xklib-relative-path-base` compiler option with one or multiple base paths of source files:

Kotlin

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinCompile::class).configureEach {
    // $base is a base path of source files
    kotlinOptions.freeCompilerArgs += "-Xklib-relative-path-base=$base"
}
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinCompile).configureEach {
    kotlinOptions {
        // $base is a base path of source files
        freeCompilerArgs += "-Xklib-relative-path-base=$base"
    }
}
```

Persisting yarn.lock for Kotlin/JS Gradle projects

The feature was backported to Kotlin 1.6.10.

The Kotlin/JS Gradle plugin now provides an ability to persist the `yarn.lock` file, making it possible to lock the versions of the npm dependencies for your project without additional Gradle configuration. The feature brings changes to the default project structure by adding the auto-generated `kotlin-js-store` directory to the project root. It holds the `yarn.lock` file inside.

We strongly recommend committing the `kotlin-js-store` directory and its contents to your version control system. Committing lockfiles to your version control system is a recommended practice because it ensures your application is being built with the exact same dependency tree on all machines, regardless of whether those are development environments on other machines or CI/CD services. Lockfiles also prevent your npm dependencies from being silently updated when a project is checked out on a new machine, which is a security concern.

Tools like Dependabot can also parse the `yarn.lock` files of your Kotlin/JS projects, and provide you with warnings if any npm package you depend on is compromised.

If needed, you can change both directory and lockfile names in the build script:

Kotlin

```
rootProject.plugins.withType<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin> {
    rootProject.the<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension>().lockFileDirectory
=
        project.rootDir.resolve("my-kotlin-js-store")
    rootProject.the<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension>().lockFileName =
"my-yarn.lock"
}
```

Groovy

```
rootProject.plugins.withType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin) {

rootProject.extensions.getByType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension).lockFile
=
        file("my-kotlin-js-store")

rootProject.extensions.getByType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension).lockFile
= 'my-yarn.lock'
}
```

Changing the name of the lockfile may cause dependency inspection tools to no longer pick up the file.

Installation of npm dependencies with --ignore-scripts by default

The feature was backported to Kotlin 1.6.10.

The Kotlin/JS Gradle plugin now prevents the execution of lifecycle scripts during the installation of npm dependencies by default. The change is aimed at reducing the likelihood of executing malicious code from compromised npm packages.

To roll back to the old configuration, you can explicitly enable lifecycle scripts execution by adding the following lines to `build.gradle(.kts)`:

Kotlin

```
rootProject.plugins.withType<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin> {
    rootProject.the<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension>().ignoreScripts =
false
}
```

Groovy

```
rootProject.plugins.withType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin) {

rootProject.extensions.getByType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension).ignoreSc
= false
}
```

Learn more about npm dependencies of a Kotlin/JS Gradle project.

Gradle

Kotlin 1.6.20 brings the following changes for the Kotlin Gradle Plugin:

- New properties `kotlin.compiler.execution.strategy` and `compilerExecutionStrategy` for defining a Kotlin compiler execution strategy
- Deprecation of the options `kapt.use.worker.api`, `kotlin.experimental.coroutines`, and `kotlin.coroutines`
- Removal of the `kotlin.parallel.tasks.in.project` build option

Properties for defining Kotlin compiler execution strategy

Before Kotlin 1.6.20, you used the system property `-Dkotlin.compiler.execution.strategy` to define a Kotlin compiler execution strategy. This property might have been inconvenient in some cases. Kotlin 1.6.20 introduces a Gradle property with the same name, `kotlin.compiler.execution.strategy`, and the compile task property `compilerExecutionStrategy`.

The system property still works, but it will be removed in future releases.

The current priority of properties is the following:

- The task property `compilerExecutionStrategy` takes priority over the system property and the Gradle property `kotlin.compiler.execution.strategy`.
- The Gradle property takes priority over the system property.

There are three compiler execution strategies that you can assign to these properties:

Strategy	Where Kotlin compiler is executed	Incremental compilation	Other characteristics
Daemon	Inside its own daemon process	Yes	*The default strategy*. Can be shared between different Gradle daemons
In process	Inside the Gradle daemon process	No	May share the heap with the Gradle daemon
Out of process	In a separate process for each call	No	—

Accordingly, the available values for `kotlin.compiler.execution.strategy` properties (both system and Gradle's) are:

1. `daemon` (default)
2. `in-process`
3. `out-of-process`

Use the Gradle property `kotlin.compiler.execution.strategy` in `gradle.properties`:

```
# gradle.properties
kotlin.compiler.execution.strategy=out-of-process
```

The available values for the `compilerExecutionStrategy` task property are:

1. `org.jetbrains.kotlin.gradle.tasks.KotlinCompilerExecutionStrategy.DAEMON` (default)
2. `org.jetbrains.kotlin.gradle.tasks.KotlinCompilerExecutionStrategy.IN_PROCESS`
3. `org.jetbrains.kotlin.gradle.tasks.KotlinCompilerExecutionStrategy.OUT_OF_PROCESS`

Use the task property `compilerExecutionStrategy` in the `build.gradle.kts` build script:

```
import org.jetbrains.kotlin.gradle.dsl.KotlinCompile
import org.jetbrains.kotlin.gradle.tasks.KotlinCompilerExecutionStrategy

// ...

tasks.withType<KotlinCompile>().configureEach {
    compilerExecutionStrategy.set(KotlinCompilerExecutionStrategy.IN_PROCESS)
}
```

Please leave your feedback in this YouTrack task.

Deprecation of build options for kapt and coroutines

In Kotlin 1.6.20, we changed deprecation levels of the properties:

- We deprecated the ability to run kapt via the Kotlin daemon with `kapt.use.worker.api` – now it produces a warning to Gradle's output. By default, kapt has been using Gradle workers since the 1.3.70 release, and we recommend sticking to this method.

  We are going to remove the option `kapt.use.worker.api` in future releases.

- We deprecated the `kotlin.experimental.coroutines` Gradle DSL option and the `kotlin.coroutines` property used in `gradle.properties`. Just use *suspending functions* or add the `kotlinx.coroutines` dependency to your `build.gradle(.kts)` file.

  Learn more about coroutines in the Coroutines guide.

Removal of the kotlin.parallel.tasks.in.project build option

In Kotlin 1.5.20, we announced the deprecation of the build option `kotlin.parallel.tasks.in.project`. This option has been removed in Kotlin 1.6.20.

Depending on the project, parallel compilation in the Kotlin daemon may require more memory. To reduce memory consumption, increase the heap size for the Kotlin daemon.

Learn more about the currently supported compiler options in the Kotlin Gradle plugin.

What's new in Kotlin 1.6.0

Released: 16 November 2021

Kotlin 1.6.0 introduces new language features, optimizations and improvements to existing features, and a lot of improvements to the Kotlin standard library.

You can also find an overview of the changes in the release blog post.

> For information about the Kotlin release cycle, see Kotlin release process.

Language

Kotlin 1.6.0 brings stabilization to several language features introduced for preview in the previous 1.5.30 release:

- Stable exhaustive when statements for enum, sealed and Boolean subjects
- Stable suspending functions as supertypes
- Stable suspend conversions
- Stable instantiation of annotation classes

It also includes various type inference improvements and support for annotations on class type parameters:

- Improved type inference for recursive generic types
- Changes to builder inference
- Support for annotations on class type parameters

Stable exhaustive when statements for enum, sealed, and Boolean subjects

An *exhaustive* `when` statement contains branches for all possible types or values of its subject, or for some types plus an `else` branch. It covers all possible cases, making your code safer.

We will soon prohibit non-exhaustive `when` statements to make the behavior consistent with `when` expressions. To ensure smooth migration, Kotlin 1.6.0 reports warnings about non-exhaustive `when` statements with an enum, sealed, or Boolean subject. These warnings will become errors in future releases.

```
sealed class Contact {
    data class PhoneCall(val number: String) : Contact()
    data class TextMessage(val number: String) : Contact()
}

fun Contact.messageCost(): Int =
    when(this) { // Error: 'when' expression must be exhaustive
        is Contact.PhoneCall -> 42
    }

fun sendMessage(contact: Contact, message: String) {
    // Starting with 1.6.0

    // Warning: Non exhaustive 'when' statements on Boolean will be
    // prohibited in 1.7, add 'false' branch or 'else' branch instead
    when(message.isEmpty()) {
        true -> return
    }
    // Warning: Non exhaustive 'when' statements on sealed class/interface will be
    // prohibited in 1.7, add 'is TextMessage' branch or 'else' branch instead
    when(contact) {
        is Contact.PhoneCall -> TODO()
    }
}
```

See this YouTrack ticket for a more detailed explanation of the change and its effects.

Stable suspending functions as supertypes

Implementation of suspending functional types has become Stable in Kotlin 1.6.0. A preview was available in 1.5.30.

The feature can be useful when designing APIs that use Kotlin coroutines and accept suspending functional types. You can now streamline your code by enclosing the desired behavior in a separate class that implements a suspending functional type.

```
class MyClickAction : suspend () -> Unit {
    override suspend fun invoke() { TODO() }
}

fun launchOnClick(action: suspend () -> Unit) {}
```

You can use an instance of this class where only lambdas and suspending function references were allowed previously: `launchOnClick(MyClickAction())`.

There are currently two limitations coming from implementation details:

- You can't mix ordinary functional types and suspending ones in the list of supertypes.
- You can't use multiple suspending functional supertypes.

Stable suspend conversions

Kotlin 1.6.0 introduces Stable conversions from regular to suspending functional types. Starting from 1.4.0, the feature supported functional literals and callable references. With 1.6.0, it works with any form of expression. As a call argument, you can now pass any expression of a suitable regular functional type where suspending is expected. The compiler will perform an implicit conversion automatically.

```
fun getSuspending(suspending: suspend () -> Unit) {}

fun suspending() {}

fun test(regular: () -> Unit) {
    getSuspending { }           // OK
    getSuspending(::suspending) // OK
    getSuspending(regular)      // OK
}
```

Stable instantiation of annotation classes

Kotlin 1.5.30 introduced experimental support for instantiation of annotation classes on the JVM platform. With 1.6.0, the feature is available by default both for Kotlin/JVM and Kotlin/JS.

Learn more about instantiation of annotation classes in this KEEP.

Improved type inference for recursive generic types

Kotlin 1.5.30 introduced an improvement to type inference for recursive generic types, which allowed their type arguments to be inferred based only on the upper bounds of the corresponding type parameters. The improvement was available with the compiler option. In version 1.6.0 and later, it is enabled by default.

```
// Before 1.5.30
val containerA = PostgreSQLContainer<Nothing>(DockerImageName.parse("postgres:13-alpine")).apply {
  withDatabaseName("db")
  withUsername("user")
  withPassword("password")
  withInitScript("sql/schema.sql")
}

// With compiler option in 1.5.30 or by default starting with 1.6.0
val containerB = PostgreSQLContainer(DockerImageName.parse("postgres:13-alpine"))
  .withDatabaseName("db")
  .withUsername("user")
  .withPassword("password")
  .withInitScript("sql/schema.sql")
```

Changes to builder inference

Builder inference is a type inference flavor which is useful when calling generic builder functions. It can infer the type arguments of a call with the help of type information from calls inside its lambda argument.

We're making multiple changes that are bringing us closer to fully stable builder inference. Starting with 1.6.0:

- You can make calls returning an instance of a not yet inferred type inside a builder lambda without specifying the `-Xunrestricted-builder-inference` compiler option introduced in 1.5.30.
- With `-Xenable-builder-inference`, you can write your own builders without applying the `@BuilderInference` annotation.

  > Note that clients of these builders will need to specify the same `-Xenable-builder-inference` compiler option.

- With the `-Xenable-builder-inference`, builder inference automatically activates if a regular type inference cannot get enough information about a type.

Learn how to write custom generic builders.

Support for annotations on class type parameters

Support for annotations on class type parameters looks like this:

```
@Target(AnnotationTarget.TYPE_PARAMETER)
annotation class BoxContent

class Box<@BoxContent T> {}
```

Annotations on all type parameters are emitted into JVM bytecode so annotation processors are able to use them.

For the motivating use case, read this YouTrack ticket.

Learn more about annotations.

Supporting previous API versions for a longer period

Starting with Kotlin 1.6.0, we will support development for three previous API versions instead of two, along with the current stable one. Currently, we support versions 1.3, 1.4, 1.5, and 1.6.

Kotlin/JVM

For Kotlin/JVM, starting with 1.6.0, the compiler can generate classes with a bytecode version corresponding to JVM 17. The new language version also includes optimized delegated properties and repeatable annotations, which we had on the roadmap:

- Repeatable annotations with runtime retention for 1.8 JVM target
- Optimize delegated properties which call get/set on the given KProperty instance

Repeatable annotations with runtime retention for 1.8 JVM target

Java 8 introduced repeatable annotations, which can be applied multiple times to a single code element. The feature requires two declarations to be present in the Java code: the repeatable annotation itself marked with `@java.lang.annotation.Repeatable` and the containing annotation to hold its values.

Kotlin also has repeatable annotations, but requires only `@kotlin.annotation.Repeatable` to be present on an annotation declaration to make it repeatable. Before 1.6.0, the feature supported only `SOURCE` retention and was incompatible with Java's repeatable annotations. Kotlin 1.6.0 removes these limitations. `@kotlin.annotation.Repeatable` now accepts any retention and makes the annotation repeatable both in Kotlin and Java. Java's repeatable annotations are now also supported from the Kotlin side.

While you can declare a containing annotation, it's not necessary. For example:

- If an annotation `@Tag` is marked with `@kotlin.annotation.Repeatable`, the Kotlin compiler automatically generates a containing annotation class under the name of `@Tag.Container`:

```
@Repeatable
annotation class Tag(val name: String)

// The compiler generates @Tag.Container containing annotation
```

- To set a custom name for a containing annotation, apply the `@kotlin.jvm.JvmRepeatable` meta-annotation and pass the explicitly declared containing annotation class as an argument:

```
@JvmRepeatable(Tags::class)
annotation class Tag(val name: String)

annotation class Tags(val value: Array<Tag>)
```

Kotlin reflection now supports both Kotlin's and Java's repeatable annotations via a new function, `KAnnotatedElement.findAnnotations()`.

Learn more about Kotlin repeatable annotations in this KEEP.

Optimize delegated properties which call get/set on the given KProperty instance

We optimized the generated JVM bytecode by omitting the `$delegate` field and generating immediate access to the referenced property.

For example, in the following code

```
class Box<T> {
    private var impl: T = ...

    var content: T by ::impl
}
```

Kotlin no longer generates the field `content$delegate`. Property accessors of the `content` variable invoke the `impl` variable directly, skipping the delegated property's `getValue` / `setValue` operators and thus avoiding the need for the property reference object of the `KProperty` type.

Thanks to our Google colleagues for the implementation!

Learn more about delegated properties.

Kotlin/Native

Kotlin/Native is receiving multiple improvements and component updates, some of them in the preview state:

- Preview of the new memory manager
- Support for Xcode 13
- Compilation of Windows targets on any host
- LLVM and linker updates
- Performance improvements
- Unified compiler plugin ABI with JVM and JS IR backends
- Detailed error messages for klib linkage failures
- Reworked unhandled exception handling API

Preview of the new memory manager

> The new Kotlin/Native memory manager is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

With Kotlin 1.6.0, you can try the development preview of the new Kotlin/Native memory manager. It moves us closer to eliminating the differences between the JVM and Native platforms to provide a consistent developer experience in multiplatform projects.

One of the notable changes is the lazy initialization of top-level properties, like in Kotlin/JVM. A top-level property gets initialized when a top-level property or function from the same file is accessed for the first time. This mode also includes global interprocedural optimization (enabled only for release binaries), which removes redundant initialization checks.

We've recently published a blog post about the new memory manager. Read it to learn about the current state of the new memory manager and find some demo projects, or jump right to the migration instructions to try it yourself. Please check how the new memory manager works on your projects and share feedback in our issue tracker, YouTrack.

Support for Xcode 13

Kotlin/Native 1.6.0 supports Xcode 13 – the latest version of Xcode. Feel free to update your Xcode and continue working on your Kotlin projects for Apple operating systems.

> New libraries added in Xcode 13 aren't available for use in Kotlin 1.6.0, but we're going to add support for them in upcoming versions.

Compilation of Windows targets on any host

Starting from 1.6.0, you don't need a Windows host to compile the Windows targets `mingwX64` and `mingwX86`. They can be compiled on any host that supports Kotlin/Native.

LLVM and linker updates

We've reworked the LLVM dependency that Kotlin/Native uses under the hood. This brings various benefits, including:

- Updated LLVM version to 11.1.0.
- Decreased dependency size. For example, on macOS it's now about 300 MB instead of 1200 MB in the previous version.
- Excluded dependency on the `ncurses5` library that isn't available in modern Linux distributions.

In addition to the LLVM update, Kotlin/Native now uses the LLD linker (a linker from the LLVM project) for MingGW targets. It provides various benefits over the previously used ld.bfd linker, and will allow us to improve runtime performance of produced binaries and support compiler caches for MinGW targets. Note that LLD requires import libraries for DLL linkage. Learn more in this Stack Overflow thread.

Performance improvements

Kotlin/Native 1.6.0 delivers the following performance improvements:

- Compilation time: compiler caches are enabled by default for `linuxX64` and `iosArm64` targets. This speeds up most compilations in debug mode (except the first one). Measurements showed about a 200% speed increase on our test projects. The compiler caches have been available for these targets since Kotlin 1.5.0 with additional Gradle properties; you can remove them now.
- Runtime: iterating over arrays with `for` loops is now up to 12% faster thanks to optimizations in the produced LLVM code.

Unified compiler plugin ABI with JVM and JS IR backends

> The option to use the common IR compiler plugin ABI for Kotlin/Native is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

In previous versions, authors of compiler plugins had to provide separate artifacts for Kotlin/Native because of the differences in the ABI.

Starting from 1.6.0, the Kotlin Multiplatform Gradle plugin is able to use the embeddable compiler jar – the one used for the JVM and JS IR backends – for Kotlin/Native. This is a step toward unification of the compiler plugin

development experience, as you can now use the same compiler plugin artifacts for Native and other supported platforms.

This is a preview version of such support, and it requires an opt-in. To start using generic compiler plugin artifacts for Kotlin/Native, add the following line to `gradle.properties`: `kotlin.native.useEmbeddableCompilerJar=true`.

We're planning to use the embeddable compiler jar for Kotlin/Native by default in the future, so it's vital for us to hear how the preview works for you.

If you are an author of a compiler plugin, please try this mode and check if it works for your plugin. Note that depending on your plugin's structure, migration steps may be required. See this YouTrack issue for migration instructions and leave your feedback in the comments.

Detailed error messages for klib linkage failures

The Kotlin/Native compiler now provides detailed error messages for klib linkage errors. The messages now have clear error descriptions, and they also include information about possible causes and ways to fix them.

For example:

- 1.5.30:

```
e: java.lang.IllegalStateException: IrTypeAliasSymbol expected: Unbound public symbol for public
kotlinx.coroutines/CancellationException|null[0]
<stack trace>
```

- 1.6.0:

```
e: The symbol of unexpected type encountered during IR deserialization: IrClassPublicSymbolImpl,
kotlinx.coroutines/CancellationException|null[0].
IrTypeAliasSymbol is expected.

This could happen if there are two libraries, where one library was compiled against the different
version of the other library than the one currently used in the project.
Please check that the project configuration is correct and has consistent versions of dependencies.

The list of libraries that depend on "org.jetbrains.kotlinx:kotlinx-coroutines-core
(org.jetbrains.kotlinx:kotlinx-coroutines-core-macosx64)" and may lead to conflicts:
<list of libraries and potential version mismatches>

Project dependencies:
<dependencies tree>
```

Reworked unhandled exception handling API

We've unified the processing of unhandled exceptions throughout the Kotlin/Native runtime and exposed the default processing as the function `processUnhandledException(throwable: Throwable)` for use by custom execution environments, like `kotlinx.coroutines`. This processing is also applied to exceptions that escape operation in `Worker.executeAfter()`, but only for the new memory manager.

API improvements also affected the hooks that have been set by `setUnhandledExceptionHook()`. Previously such hooks were reset after the Kotlin/Native runtime called the hook with an unhandled exception, and the program would always terminate right after. Now these hooks may be used more than once, and if you want the program to always terminate on an unhandled exception, either do not set an unhandled exception hook (`setUnhandledExceptionHook()`), or make sure to call `terminateWithUnhandledException()` at the end of your hook. This will help you send exceptions to a third-party crash reporting service (like Firebase Crashlytics) and

then terminate the program. Exceptions that escape `main()` and exceptions that cross the interop boundary will always terminate the program, even if the hook did not call `terminateWithUnhandledException()`.

Kotlin/JS

We're continuing to work on stabilizing the IR backend for the Kotlin/JS compiler. Kotlin/JS now has an option to disable downloading of Node.js and Yarn.

Option to use pre-installed Node.js and Yarn

You can now disable downloading Node.js and Yarn when building Kotlin/JS projects and use the instances already installed on the host. This is useful for building on servers without internet connectivity, such as CI servers.

To disable downloading external components, add the following lines to your `build.gradle(.kts)`:

- Yarn:

Kotlin

```
rootProject.plugins.withType<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin> {
    rootProject.the<org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension>().download =
false // or true for default behavior
}
```

Groovy

```
rootProject.plugins.withType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnPlugin) {

rootProject.extensions.getByType(org.jetbrains.kotlin.gradle.targets.js.yarn.YarnRootExtension).downl
= false
}
```

- Node.js:

Kotlin

```
rootProject.plugins.withType<org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsRootPlugin> {
    rootProject.the<org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsRootExtension>().download =
false // or true for default behavior
}
```

Groovy

```
rootProject.plugins.withType(org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsRootPlugin) {

rootProject.extensions.getByType(org.jetbrains.kotlin.gradle.targets.js.nodejs.NodeJsRootExtension).d
= false
}
```

Kotlin Gradle plugin

In Kotlin 1.6.0, we changed the deprecation level of the `KotlinGradleSubplugin` class to 'ERROR'. This class was used for writing compiler plugins. In the following releases, we'll remove this class. Use the class `KotlinCompilerPluginSupportPlugin` instead.

We removed the `kotlin.useFallbackCompilerSearch` build option and the `noReflect` and `includeRuntime` compiler options. The `useIR` compiler option has been hidden and will be removed in upcoming releases.

Learn more about the currently supported compiler options in the Kotlin Gradle plugin.

Standard library

The new 1.6.0 version of the standard library stabilizes experimental features, introduces new ones, and unifies its behavior across the platforms:

- New readline functions
- Stable typeOf()
- Stable collection builders
- Stable Duration API
- Splitting Regex into a sequence
- Bit rotation operations on integers
- Changes for replace() and replaceFirst() in JS
- Improvements to the existing API
- Deprecations

New readline functions

Kotlin 1.6.0 offers new functions for handling standard input: `readln()` and `readlnOrNull()`.

For now, new functions are available for the JVM and Native target platforms only.

Earlier versions	1.6.0 alternative	Usage
`readLine()!!`	`readln()`	Reads a line from stdin and returns it, or throws a `RuntimeException` if EOF has been reached.
`readLine()`	`readlnOrNull()`	Reads a line from stdin and returns it, or returns `null` if EOF has been reached.

We believe that eliminating the need to use `!!` when reading a line will improve the experience for newcomers and simplify teaching Kotlin. To make the read-line operation name consistent with its `println()` counterpart, we've decided to shorten the names of new functions to 'ln'.

```
println("What is your nickname?")
val nickname = readln()
println("Hello, $nickname!")
```

```
fun main() {
    var sum = 0
    while (true) {
        val nextLine = readlnOrNull().takeUnless {
            it.isNullOrEmpty()
        } ?: break
        sum += nextLine.toInt()
    }
    println(sum)
}
```

The existing `readLine()` function will get a lower priority than `readln()` and `readlnOrNull()` in your IDE code completion. IDE inspections will also recommend using new functions instead of the legacy `readLine()`.

We're planning to gradually deprecate the `readLine()` function in future releases.

Stable typeOf()

Version 1.6.0 brings a Stable `typeOf()` function, closing one of the major roadmap items.

Since 1.3.40, `typeOf()` was available on the JVM platform as an experimental API. Now you can use it in any Kotlin platform and get `KType` representation of any Kotlin type that the compiler can infer:

```
inline fun <reified T> renderType(): String {
    val type = typeOf<T>()
    return type.toString()
}

fun main() {
    val fromExplicitType = typeOf<Int>()
    val fromReifiedType = renderType<List<Int>>()
}
```

Stable collection builders

In Kotlin 1.6.0, collection builder functions have been promoted to Stable. Collections returned by collection builders are now serializable in their read-only state.

You can now use `buildMap()`, `buildList()`, and `buildSet()` without the opt-in annotation:

```
fun main() {
    val x = listOf('b', 'c')
    val y = buildList {
        add('a')
        addAll(x)
        add('d')
    }
    println(y)  // [a, b, c, d]
}
```

Stable Duration API

The Duration class for representing duration amounts in different time units has been promoted to Stable. In 1.6.0, the Duration API has received the following changes:

- The first component of the `toComponents()` function that decomposes the duration into days, hours, minutes, seconds, and nanoseconds now has the `Long` type instead of `Int`. Before, if the value didn't fit into the `Int` range, it was coerced into that range. With the `Long` type, you can decompose any value in the duration range without cutting off the values that don't fit into `Int`.
- The `DurationUnit` enum is now standalone and not a type alias of `java.util.concurrent.TimeUnit` on the JVM. We haven't found any convincing cases in which having `typealias DurationUnit = TimeUnit` could be useful. Also, exposing the `TimeUnit` API through a type alias might confuse `DurationUnit` users.
- In response to community feedback, we're bringing back extension properties like `Int.seconds`. But we'd like to limit their applicability, so we put them into the companion of the `Duration` class. While the IDE can still propose extensions in completion and automatically insert an import from the companion, in the future we plan to limit this behavior to cases when the `Duration` type is expected.

  ```
  import kotlin.time.Duration.Companion.seconds

  fun main() {
      val duration = 10000
      println("There are ${duration.seconds.inWholeMinutes} minutes in $duration seconds")
      // There are 166 minutes in 10000 seconds
  }
  ```

  We suggest replacing previously introduced companion functions, such as `Duration.seconds(Int)`, and deprecated top-level extensions like `Int.seconds` with new extensions in `Duration.Companion`.

  > Such a replacement may cause ambiguity between old top-level extensions and new companion extensions. Be sure to use the wildcard import of the kotlin.time package – `import kotlin.time.*` – before doing automated migration.

Splitting Regex into a sequence

The `Regex.splitToSequence(CharSequence)` and `CharSequence.splitToSequence(Regex)` functions are promoted to Stable. They split the string around matches of the given regex, but return the result as a Sequence so that all operations on this result are executed lazily:

```
fun main() {
    val colorsText = "green, red, brown&blue, orange, pink&green"
    val regex = "[,\\s]+".toRegex()
    val mixedColor = regex.splitToSequence(colorsText)
    // or
    // val mixedColor = colorsText.splitToSequence(regex)
        .onEach { println(it) }
        .firstOrNull { it.contains('&') }
    println(mixedColor) // "brown&blue"
}
```

Bit rotation operations on integers

In Kotlin 1.6.0, the `rotateLeft()` and `rotateRight()` functions for bit manipulations became Stable. The functions rotate the binary representation of the number left or right by a specified number of bits:

```
fun main() {
    val number: Short = 0b10001
    println(number
        .rotateRight(2)
        .toString(radix = 2)) // 100000000000100
    println(number
        .rotateLeft(2)
        .toString(radix = 2))  // 1000100
}
```

Changes for replace() and replaceFirst() in JS

Before Kotlin 1.6.0, the `replace()` and `replaceFirst()` Regex functions behaved differently in Java and JS when the replacement string contained a group reference. To make the behavior consistent across all target platforms, we've changed their implementation in JS.

Occurrences of `${name}` or `$index` in the replacement string are substituted with the subsequences corresponding to the captured groups with the specified index or a name:

- `$index` – the first digit after '$' is always treated as a part of the group reference. Subsequent digits are incorporated into the `index` only if they form a valid group reference.Only digits '0'–'9' are considered potential components of the group reference. Note that indexes of captured groups start from '1'. The group with index '0' stands for the whole match.
- `${name}` – the `name` can consist of Latin letters 'a'–'z', 'A'–'Z', or digits '0'–'9'. The first character must be a letter.

  > Named groups in replacement patterns are currently supported only on the JVM.

- To include the succeeding character as a literal in the replacement string, use the backslash character `\` :

  ```
  fun main() {
      println(Regex("(.+)").replace("Kotlin", """\$ $1""")) // $ Kotlin
      println(Regex("(.+)").replaceFirst("1.6.0", """\\ $1""")) // \ 1.6.0
  }
  ```

  You can use `Regex.escapeReplacement()` if the replacement string has to be treated as a literal string.

Improvements to the existing API

- Version 1.6.0 added the infix extension function for `Comparable.compareTo()`. You can now use the infix form for comparing two objects for order:

  ```
  class WrappedText(val text: String) : Comparable<WrappedText> {
       override fun compareTo(other: WrappedText): Int =
           this.text compareTo other.text
  }
  ```

- `Regex.replace()` in JS is now also not inline to unify its implementation across all platforms.
- The `compareTo()` and `equals()` String functions, as well as the `isBlank()` CharSequence function now behave in JS exactly the same way they do on the JVM. Previously there were deviations when it came to non-ASCII characters.

Deprecations

In Kotlin 1.6.0, we're starting the deprecation cycle with a warning for some JS-only stdlib API.

concat(), match(), and matches() string functions

- To concatenate the string with the string representation of a given other object, use `plus()` instead of `concat()`.
- To find all occurrences of a regular expression within the input, use `findAll()` of the Regex class instead of `String.match(regex: String)`.
- To check if the regular expression matches the entire input, use `matches()` of the Regex class instead of `String.matches(regex: String)`.

sort() on arrays taking comparison functions

We've deprecated the `Array<out T>.sort()` function and the inline functions `ByteArray.sort()`, `ShortArray.sort()`, `IntArray.sort()`, `LongArray.sort()`, `FloatArray.sort()`, `DoubleArray.sort()`, and `CharArray.sort()`, which sorted arrays following the order passed by the comparison function. Use other standard library functions for array sorting.

See the collection ordering section for reference.

Tools

Kover – a code coverage tool for Kotlin

The Kover Gradle plugin is Experimental. We would appreciate your feedback on it in GitHub.

With Kotlin 1.6.0, we're introducing Kover – a Gradle plugin for the IntelliJ and JaCoCo Kotlin code coverage agents. It works with all language constructs, including inline functions.

Learn more about Kover on its GitHub repository or in this video:

Watch video online.

Coroutines 1.6.0-RC

`kotlinx.coroutines` 1.6.0-RC is out with multiple features and improvements:

- Support for the new Kotlin/Native memory manager
- Introduction of dispatcher *views* API, which allows limiting parallelism without creating additional threads
- Migrating from Java 6 to Java 8 target
- `kotlinx-coroutines-test` with the new reworked API and multiplatform support
- Introduction of `CopyableThreadContextElement`, which gives coroutines a thread-safe write access to `ThreadLocal` variables

Learn more in the changelog.

Migrating to Kotlin 1.6.0

IntelliJ IDEA and Android Studio will suggest updating the Kotlin plugin to 1.6.0 once it is available.

To migrate existing projects to Kotlin 1.6.0, change the Kotlin version to `1.6.0` and reimport your Gradle or Maven project. Learn how to update to Kotlin 1.6.0.

To start a new project with Kotlin 1.6.0, update the Kotlin plugin and run the Project Wizard from **File** | **New** | **Project**.

The new command-line compiler is available for download on the GitHub release page.

Kotlin 1.6.0 is a feature release and can, therefore, bring changes that are incompatible with your code written for earlier versions of the language. Find the detailed list of such changes in the Compatibility Guide for Kotlin 1.6.

Compatibility guide for Kotlin 1.6.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.5 to Kotlin 1.6.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language

Make when statements with enum, sealed, and Boolean subjects exhaustive by default

Issue: KT-47709

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will warn about the `when` statement with an enum, sealed, or Boolean subject being non-exhaustive

Deprecation cycle:

- 1.6.0: introduce a warning when the `when` statement with an enum, sealed, or Boolean subject is non-exhaustive (error in the progressive mode)
- 1.7.0: raise this warning to an error

Deprecate confusing grammar in when-with-subject

Issue: KT-48385

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will deprecate several confusing grammar constructs in `when` condition expressions

Deprecation cycle:

- 1.6.20: introduce a deprecation warning on the affected expressions
- 1.8.0: raise this warning to an error
- >= 1.8: repurpose some deprecated constructs for new language features

Prohibit access to class members in the super constructor call of its companion and nested objects

Issue: KT-25289

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will report an error for arguments of super constructor call of companion and regular objects if the receiver of such arguments refers to the containing declaration

Deprecation cycle:

- 1.5.20: introduce a warning on the problematic arguments
- 1.6.0: raise this warning to an error, `-XXLanguage:-ProhibitSelfCallsInNestedObjects` can be used to temporarily revert to the pre-1.6 behavior

Type nullability enhancement improvements

Issue: KT-48623

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.7 will change how it loads and interprets type nullability annotations in Java code

Deprecation cycle:

- 1.4.30: introduce warnings for cases where more precise type nullability could lead to an error
- 1.7.0: infer more precise nullability of Java types, `-XXLanguage:-TypeEnhancementImprovementsInStrictMode` can be used to temporarily revert to the pre-1.7 behavior

Prevent implicit coercions between different numeric types

Issue: KT-48645

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin will avoid converting numeric values automatically to a primitive numeric type where only a downcast to that type was needed semantically

Deprecation cycle:

- < 1.5.30: the old behavior in all affected cases
- 1.5.30: fix the downcast behavior in generated property delegate accessors, `-Xuse-old-backend` can be used to temporarily revert to the pre-1.5.30 fix behavior
- >= 1.6.20: fix the downcast behavior in other affected cases

Prohibit declarations of repeatable annotation classes whose container annotation violates JLS

Issue: KT-47928

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.6 will check that the container annotation of a repeatable annotation satisfies the same requirements as in JLS 9.6.3: array-typed value method, retention, and target

Deprecation cycle:

- 1.5.30: introduce a warning on repeatable container annotation declarations violating JLS requirements (error in the progressive mode)
- 1.6.0: raise this warning to an error, `-XXLanguage:-RepeatableAnnotationContainerConstraints` can be used to temporarily disable the error reporting

Prohibit declaring a nested class named Container in a repeatable annotation class

Issue: KT-47971

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.6 will check that a repeatable annotation declared in Kotlin doesn't have a nested class with the predefined name `Container`

Deprecation cycle:

- 1.5.30: introduce a warning on nested classes with the name `Container` in a Kotlin-repeatable annotation class (error in the progressive mode)
- 1.6.0: raise this warning to an error, `-XXLanguage:-RepeatableAnnotationContainerConstraints` can be used to temporarily disable the error reporting

Prohibit @JvmField on a property in the primary constructor that overrides an interface property

Issue: KT-32753

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.6 will outlaw annotating a property declared in the primary constructor that overrides an interface property with the `@JvmField` annotation

Deprecation cycle:

- 1.5.20: introduce a warning on the `@JvmField` annotation on such properties in the primary constructor
- 1.6.0: raise this warning to an error, `-XXLanguage:-ProhibitJvmFieldOnOverrideFromInterfaceInPrimaryConstructor` can be used to temporarily disable the error reporting

Deprecate the enable and the compatibility modes of the compiler option -Xjvm-default

Issue: KT-46329

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.6.20 will warn about the usage of `enable` and `compatibility` modes of the `-Xjvm-default` compiler option

Deprecation cycle:

- 1.6.20: introduce a warning on the `enable` and `compatibility` modes of the `-Xjvm-default` compiler option
- >= 1.8.0: raise this warning to an error

Prohibit super calls from public-abi inline functions

Issue: KT-45379

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will outlaw calling functions with a `super` qualifier from public or protected inline functions and properties

Deprecation cycle:

- 1.5.0: introduce a warning on super calls from public or protected inline functions or property accessors
- 1.6.0: raise this warning to an error, `-XXLanguage:-ProhibitSuperCallsFromPublicInline` can be used to temporarily disable the error reporting

Prohibit protected constructor calls from public inline functions

Issue: KT-48860

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will outlaw calling protected constructors from public or protected inline functions and properties

Deprecation cycle:

- 1.4.30: introduce a warning on protected constructor calls from public or protected inline functions or property accessors
- 1.6.0: raise this warning to an error, `-XXLanguage:-ProhibitProtectedConstructorCallFromPublicInline` can be used to temporarily disable the error reporting

Prohibit exposing private nested types from private-in-file types

Issue: KT-20094

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will outlaw exposing private nested types and inner classes from private-in-file types

Deprecation cycle:

- 1.5.0: introduce a warning on private types exposed from private-in-file types
- 1.6.0: raise this warning to an error, `-XXLanguage:-PrivateInFileEffectiveVisibility` can be used to temporarily disable the error reporting

Annotation target is not analyzed in several cases for annotations on a type

Issue: KT-28449

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will no longer allow annotations on types that should not be applicable to types

Deprecation cycle:

- 1.5.20: introduce an error in the progressive mode
- 1.6.0: introduce an error, `-XXLanguage:-ProperCheckAnnotationsTargetInTypeUsePositions` can be used to temporarily disable the error reporting

Prohibit calls to functions named suspend with a trailing lambda

Issue: KT-22562

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.6 will no longer allow calling functions named `suspend` that have the single argument of a functional type passed as a trailing lambda

Deprecation cycle:

- 1.3.0: introduce a warning on such function calls
- 1.6.0: raise this warning to an error
- >= 1.7.0: introduce changes to the language grammar, so that `suspend` before `{` is parsed as a keyword

Standard library

Remove brittle contains optimization in minus/removeAll/retainAll

Issue: KT-45438

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: Kotlin 1.6 will no longer perform conversion to set for the argument of functions and operators that remove several elements from collection/iterable/array/sequence.

Deprecation cycle:

- < 1.6: the old behavior: the argument is converted to set in some cases
- 1.6.0: if the function argument is a collection, it's no longer converted to `Set`. If it's not a collection, it can be converted to `List` instead.
  The old behavior can be temporarily turned back on JVM by setting the system property `kotlin.collections.convert_arg_to_set_in_removeAll=true`
- >= 1.7: the system property above will no longer have an effect

Change value generation algorithm in Random.nextLong

Issue: KT-47304

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: Kotlin 1.6 changes the value generation algorithm in the `Random.nextLong` function to avoid producing values out of the specified range.

Deprecation cycle:

- 1.6.0: the behavior is fixed immediately

Gradually change the return type of collection min and max functions to non-nullable

Issue: KT-38854

Component: kotlin-stdlib

Incompatible change type: source

Short summary: the return type of collection `min` and `max` functions will be changed to non-nullable in Kotlin 1.7

Deprecation cycle:

- 1.4.0: introduce `...OrNull` functions as synonyms and deprecate the affected API (see details in the issue)
- 1.5.0: raise the deprecation level of the affected API to an error
- 1.6.0: hide the deprecated functions from the public API
- >= 1.7: reintroduce the affected API but with non-nullable return type

Deprecate floating-point array functions: contains, indexOf, lastIndexOf

Issue: KT-28753

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Kotlin deprecates floating-point array functions `contains`, `indexOf`, `lastIndexOf` that compare values using the IEEE-754 order instead of the total order

Deprecation cycle:

- 1.4.0: deprecate the affected functions with a warning
- 1.6.0: raise the deprecation level to an error
- >= 1.7: hide the deprecated functions from the public API

Migrate declarations from kotlin.dom and kotlin.browser packages to kotlinx.*

Issue: KT-39330

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: declarations from the `kotlin.dom` and `kotlin.browser` packages are moved to the corresponding `kotlinx.*` packages to prepare for extracting them from stdlib

Deprecation cycle:

- 1.4.0: introduce the replacement API in `kotlinx.dom` and `kotlinx.browser` packages
- 1.4.0: deprecate the API in `kotlin.dom` and `kotlin.browser` packages and propose the new API above as a replacement
- 1.6.0: raise the deprecation level to an error
- >= 1.7: remove the deprecated functions from stdlib
- >= 1.7: move the API in kotlinx.* packages to a separate library

Make Regex.replace function not inline in Kotlin/JS

Issue: KT-27738

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: the `Regex.replace` function with the functional `transform` parameter will no longer be inline in Kotlin/JS

Deprecation cycle:

- 1.6.0: remove the `inline` modifier from the affected function

Different behavior of the Regex.replace function in JVM and JS when replacement string contains group reference

Issue: KT-28378

Component: kotlin-stdlib (JS)

Incompatible change type: behavioral

Short summary: the function `Regex.replace` in Kotlin/JS with the replacement pattern string will follow the same syntax of that pattern as in Kotlin/JVM

Deprecation cycle:

- 1.6.0: change the replacement pattern handling in `Regex.replace` of the Kotlin/JS stdlib

Use the Unicode case folding in JS Regex

Issue: KT-45928

Component: kotlin-stdlib (JS)

Incompatible change type: behavioral

Short summary: the `Regex` class in Kotlin/JS will use `unicode` flag when calling the underlying JS Regular expressions engine to search and compare characters according to the Unicode rules. This brings certain version requirements of the JS environment and causes more strict validation of unnecessary escaping in the regex pattern string.

Deprecation cycle:

- 1.5.0: enable the Unicode case folding in most functions of the JS `Regex` class
- 1.6.0: enable the Unicode case folding in the `Regex.replaceFirst` function

Deprecate some JS-only API

Issue: KT-48587

Component: kotlin-stdlib (JS)

Incompatible change type: source

Short summary: a number of JS-only functions in stdlib are deprecated for removal. They include: `String.concat(String)`, `String.match(regex: String)`, `String.matches(regex: String)`, and the `sort` functions on arrays taking a comparison function, for example, `Array<out T>.sort(comparison: (a: T, b: T) -> Int)`

Deprecation cycle:

- 1.6.0: deprecate the affected functions with a warning
- 1.7.0: raise the deprecation level to an error
- 1.8.0: remove the deprecated functions from the public API

Hide implementation- and interop-specific functions from the public API of classes in Kotlin/JS

Issue: KT-48587

Component: kotlin-stdlib (JS)

Incompatible change type: source, binary

Short summary: the functions `HashMap.createEntrySet` and `AbstactMutableCollection.toJSON` change their visibility to internal

Deprecation cycle:

- 1.6.0: make the functions internal, thus removing them from the public API

Tools

Deprecate KotlinGradleSubplugin class

Issue: KT-48830

Component: Gradle

Incompatible change type: source

Short summary: the class `KotlinGradleSubplugin` will be deprecated in favor of `KotlinCompilerPluginSupportPlugin`

Deprecation cycle:

- 1.6.0: raise the deprecation level to an error
- >= 1.7.0: remove the deprecated class

Remove kotlin.useFallbackCompilerSearch build option

Issue: KT-46719

Component: Gradle

Incompatible change type: source

Short summary: remove the deprecated 'kotlin.useFallbackCompilerSearch' build option

Deprecation cycle:

- 1.5.0: raise the deprecation level to a warning
- 1.6.0: remove the deprecated option

Remove several compiler options

Issue: KT-48847

Component: Gradle

Incompatible change type: source

Short summary: remove the deprecated `noReflect` and `includeRuntime` compiler options

Deprecation cycle:

- 1.5.0: raise the deprecation level to an error
- 1.6.0: remove the deprecated options

Deprecate useIR compiler option

Issue: KT-48847

Component: Gradle

Incompatible change type: source

Short summary: hide the deprecated `useIR` compiler option

Deprecation cycle:

- 1.5.0: raise the deprecation level to a warning
- 1.6.0: hide the option
- >= 1.7.0: remove the deprecated option

Deprecate kapt.use.worker.api Gradle property

Issue: KT-48826

Component: Gradle

Incompatible change type: source

Short summary: deprecate the `kapt.use.worker.api` property that allowed to run kapt via Gradle Workers API (default: true)

Deprecation cycle:

- 1.6.20: raise the deprecation level to a warning
- >= 1.8.0: remove this property

Remove kotlin.parallel.tasks.in.project Gradle property

Issue: KT-46406

Component: Gradle

Incompatible change type: source

Short summary: remove the `kotlin.parallel.tasks.in.project` property

Deprecation cycle:

- 1.5.20: raise the deprecation level to a warning
- 1.6.20: remove this property

Deprecate kotlin.experimental.coroutines Gradle DSL option and kotlin.coroutines Gradle property

Issue: KT-50369

Component: Gradle

Incompatible change type: source

Short summary: deprecate the `kotlin.experimental.coroutines` Gradle DSL option and the `kotlin.coroutines` property

Deprecation cycle:

- 1.6.20: raise the deprecation level to a warning
- >= 1.7.0: remove the DSL option and the property

What's new in Kotlin 1.5.30

Released: 24 August 2021

Kotlin 1.5.30 offers language updates including previews of future changes, various improvements in platform support and tooling, and new standard library functions.

Here are some major improvements:

- Language features, including experimental sealed `when` statements, changes in using opt-in requirement, and others
- Native support for Apple silicon
- Kotlin/JS IR backend reaches Beta
- Improved Gradle plugin experience

You can also find a short overview of the changes in the release blog post and this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

Language features

Kotlin 1.5.30 is presenting previews of future language changes and bringing improvements to the opt-in requirement mechanism and type inference:

- Exhaustive when statements for sealed and Boolean subjects
- Suspending functions as supertypes
- Requiring opt-in on implicit usages of experimental APIs
- Changes to using opt-in requirement annotations with different targets
- Improvements to type inference for recursive generic types

- Eliminating builder inference restrictions

Exhaustive when statements for sealed and Boolean subjects

> Support for sealed (exhaustive) when statements is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

An *exhaustive* `when` statement contains branches for either all possible types or values of its subject, or for certain types and includes an `else` branch to cover any remaining cases.

We're planning to prohibit non-exhaustive `when` statements soon to make the behavior consistent with `when` expressions. To ensure smooth migration, you can configure the compiler to report warnings about non-exhaustive `when` statements with a sealed class or a Boolean. Such warnings will appear by default in Kotlin 1.6 and will become errors later.

> Enums already get a warning.

```
sealed class Mode {
    object ON : Mode()
    object OFF : Mode()
}

fun main() {
    val x: Mode = Mode.ON
    when (x) {
        Mode.ON -> println("ON")
    }
// WARNING: Non exhaustive 'when' statements on sealed classes/interfaces
// will be prohibited in 1.7, add an 'OFF' or 'else' branch instead

    val y: Boolean = true
    when (y) {
        true -> println("true")
    }
// WARNING: Non exhaustive 'when' statements on Booleans will be prohibited
// in 1.7, add a 'false' or 'else' branch instead
}
```

To enable this feature in Kotlin 1.5.30, use language version `1.6`. You can also change the warnings to errors by enabling progressive mode.

Kotlin

```
kotlin {
    sourceSets.all {
        languageSettings.apply {
            languageVersion = "1.6"
            //progressiveMode = true // false by default
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets.all {
        languageSettings {
            languageVersion = '1.6'
            //progressiveMode = true // false by default
        }
    }
}
```

Suspending functions as supertypes

Support for suspending functions as supertypes is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.5.30 provides a preview of the ability to use a `suspend` functional type as a supertype with some limitations.

```
class MyClass: suspend () -> Unit {
    override suspend fun invoke() { TODO() }
}
```

Use the `-language-version 1.6` compiler option to enable the feature:

Kotlin

```
kotlin {
    sourceSets.all {
        languageSettings.apply {
            languageVersion = "1.6"
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets.all {
        languageSettings {
            languageVersion = '1.6'
        }
    }
}
```

The feature has the following restrictions:

- You can't mix an ordinary functional type and a `suspend` functional type as supertype. This is because of the implementation details of `suspend` functional types in the JVM backend. They are represented in it as ordinary

functional types with a marker interface. Because of the marker interface, there is no way to tell which of the superinterfaces are suspended and which are ordinary.

- You can't use multiple `suspend` functional supertypes. If there are type checks, you also can't use multiple ordinary functional supertypes.

Requiring opt-in on implicit usages of experimental APIs

> The opt-in requirement mechanism is Experimental. It may change at any time. See how to opt-in. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

The author of a library can mark an experimental API as requiring opt-in to inform users about its experimental state. The compiler raises a warning or error when the API is used and requires explicit consent to suppress it.

In Kotlin 1.5.30, the compiler treats any declaration that has an experimental type in the signature as experimental. Namely, it requires opt-in even for implicit usages of an experimental API. For example, if the function's return type is marked as an experimental API element, a usage of the function requires you to opt-in even if the declaration is not marked as requiring an opt-in explicitly.

```
// Library code

@RequiresOptIn(message = "This API is experimental.")
@Retention(AnnotationRetention.BINARY)
@Target(AnnotationTarget.CLASS)
annotation class MyDateTime // Opt-in requirement annotation

@MyDateTime
class DateProvider // A class requiring opt-in

// Client code

// Warning: experimental API usage
fun createDateSource(): DateProvider { /* ... */ }

fun getDate(): Date {
    val dateSource = createDateSource() // Also warning: experimental API usage
    // ...
}
```

Learn more about opt-in requirements.

Changes to using opt-in requirement annotations with different targets

> The opt-in requirement mechanism is Experimental. It may change at any time. See how to opt-in. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.5.30 presents new rules for using and declaring opt-in requirement annotations on different targets. The compiler now reports an error for use cases that are impractical to handle at compile time. In Kotlin 1.5.30:

- Marking local variables and value parameters with opt-in requirement annotations is forbidden at the use site.
- Marking override is allowed only if its basic declaration is also marked.
- Marking backing fields and getters is forbidden. You can mark the basic property instead.

- Setting `TYPE` and `TYPE_PARAMETER` annotation targets is forbidden at the opt-in requirement annotation declaration site.

Learn more about opt-in requirements.

Improvements to type inference for recursive generic types

In Kotlin and Java, you can define a recursive generic type, which references itself in its type parameters. In Kotlin 1.5.30, the Kotlin compiler can infer a type argument based only on upper bounds of the corresponding type parameter if it is a recursive generic. This makes it possible to create various patterns with recursive generic types that are often used in Java to make builder APIs.

```
// Kotlin 1.5.20
val containerA = PostgreSQLContainer<Nothing>(DockerImageName.parse("postgres:13-alpine")).apply {
    withDatabaseName("db")
    withUsername("user")
    withPassword("password")
    withInitScript("sql/schema.sql")
}

// Kotlin 1.5.30
val containerB = PostgreSQLContainer(DockerImageName.parse("postgres:13-alpine"))
    .withDatabaseName("db")
    .withUsername("user")
    .withPassword("password")
    .withInitScript("sql/schema.sql")
```

You can enable the improvements by passing the `-Xself-upper-bound-inference` or the `-language-version 1.6` compiler options. See other examples of newly supported use cases in this YouTrack ticket.

Eliminating builder inference restrictions

Builder inference is a special kind of type inference that allows you to infer the type arguments of a call based on type information from other calls inside its lambda argument. This can be useful when calling generic builder functions such as `buildList()` or `sequence()`: `buildList { add("string") }`.

Inside such a lambda argument, there was previously a limitation on using the type information that the builder inference tries to infer. This means you can only specify it and cannot get it. For example, you cannot call `get()` inside a lambda argument of `buildList()` without explicitly specified type arguments.

Kotlin 1.5.30 removes these limitations with the `-Xunrestricted-builder-inference` compiler option. Add this option to enable previously prohibited calls inside a lambda argument of generic builder functions:

```
@kotlin.ExperimentalStdlibApi
val list = buildList {
    add("a")
    add("b")
    set(1, null)
    val x = get(1)
    if (x != null) {
        removeAt(1)
    }
}

@kotlin.ExperimentalStdlibApi
val map = buildMap {
    put("a", 1)
    put("b", 1.1)
    put("c", 2f)
}
```

Also, you can enable this feature with the `-language-version 1.6` compiler option.

Kotlin/JVM

With Kotlin 1.5.30, Kotlin/JVM receives the following features:

- Instantiation of annotation classes
- Improved nullability annotation support configuration

See the Gradle section for Kotlin Gradle plugin updates on the JVM platform.

Instantiation of annotation classes

> Instantiation of annotation classes is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

With Kotlin 1.5.30 you can now call constructors of annotation classes in arbitrary code to obtain a resulting instance. This feature covers the same use cases as the Java convention that allows the implementation of an annotation interface.

```
annotation class InfoMarker(val info: String)

fun processInfo(marker: InfoMarker) = ...

fun main(args: Array<String>) {
    if (args.size != 0)
        processInfo(getAnnotationReflective(args))
    else
        processInfo(InfoMarker("default"))
}
```

Use the `-language-version 1.6` compiler option to enable this feature. Note that all current annotation class limitations, such as restrictions to define non-`val` parameters or members different from secondary constructors, remain intact.

Learn more about instantiation of annotation classes in this KEEP

Improved nullability annotation support configuration

The Kotlin compiler can read various types of nullability annotations to get nullability information from Java. This information allows it to report nullability mismatches in Kotlin when calling Java code.

In Kotlin 1.5.30, you can specify whether the compiler reports a nullability mismatch based on the information from specific types of nullability annotations. Just use the compiler option `-Xnullability-annotations=@<package-name>:<report-level>`. In the argument, specify the fully qualified nullability annotations package and one of these report levels:

- `ignore` to ignore nullability mismatches
- `warn` to report warnings
- `strict` to report errors.

See the full list of supported nullability annotations along with their fully qualified package names.

Here is an example showing how to enable error reporting for the newly supported RxJava 3 nullability annotations: `-Xnullability-annotations=@io.reactivex.rxjava3.annotations:strict`. Note that all such nullability mismatches are warnings by default.

Kotlin/Native

Kotlin/Native has received various changes and improvements:

- Apple silicon support
- Improved Kotlin DSL for the CocoaPods Gradle plugin
- Experimental interoperability with Swift 5.5 async/await
- Improved Swift/Objective-C mapping for objects and companion objects
- Deprecation of linkage against DLLs without import libraries for MinGW targets

Apple silicon support

Kotlin 1.5.30 introduces native support for Apple silicon.

Previously, the Kotlin/Native compiler and tooling required the Rosetta translation environment for working on Apple silicon hosts. In Kotlin 1.5.30, the translation environment is no longer needed – the compiler and tooling can run on Apple silicon hardware without requiring any additional actions.

We've also introduced new targets that make Kotlin code run natively on Apple silicon:

- `macosArm64`
- `iosSimulatorArm64`
- `watchosSimulatorArm64`
- `tvosSimulatorArm64`

They are available on both Intel-based and Apple silicon hosts. All existing targets are available on Apple silicon hosts as well.

Note that in 1.5.30 we provide only basic support for Apple silicon targets in the `kotlin-multiplatform` Gradle plugin. Particularly, the new simulator targets aren't included in the `ios`, `tvos`, and `watchos` target shortcuts. We will keep working to improve the user experience with the new targets.

Improved Kotlin DSL for the CocoaPods Gradle plugin

New parameters for Kotlin/Native frameworks

Kotlin 1.5.30 introduces the improved CocoaPods Gradle plugin DSL for Kotlin/Native frameworks. In addition to the name of the framework, you can specify other parameters in the Pod configuration:

- Specify the dynamic or static version of the framework
- Enable export dependencies explicitly
- Enable Bitcode embedding

To use the new DSL, update your project to Kotlin 1.5.30, and specify the parameters in the `cocoapods` section of your `build.gradle(.kts)` file:

```
cocoapods {
    frameworkName = "MyFramework" // This property is deprecated
    // and will be removed in future versions
    // New DSL for framework configuration:
    framework {
        // All Framework properties are supported
        // Framework name configuration. Use this property instead of
        // deprecated 'frameworkName'
        baseName = "MyFramework"
        // Dynamic framework support
        isStatic = false
        // Dependency export
        export(project(":anotherKMMModule"))
        transitiveExport = false // This is default.
        // Bitcode embedding
        embedBitcode(BITCODE)
    }
}
```

Support custom names for Xcode configuration

The Kotlin CocoaPods Gradle plugin supports custom names in the Xcode build configuration. It will also help you if you're using special names for the build configuration in Xcode, for example `Staging`.

To specify a custom name, use the `xcodeConfigurationToNativeBuildType` parameter in the `cocoapods` section of your `build.gradle(.kts)` file:

```
cocoapods {
    // Maps custom Xcode configuration to NativeBuildType
    xcodeConfigurationToNativeBuildType["CUSTOM_DEBUG"] = NativeBuildType.DEBUG
    xcodeConfigurationToNativeBuildType["CUSTOM_RELEASE"] = NativeBuildType.RELEASE
}
```

This parameter will not appear in the Podspec file. When Xcode runs the Gradle build process, the Kotlin CocoaPods Gradle plugin will select the necessary native build type.

> There's no need to declare the `Debug` and `Release` configurations because they are supported by default.

Experimental interoperability with Swift 5.5 async/await

> Concurrency interoperability with Swift async/await is Experimental. It may be dropped or changed at any time. You should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

We added support for calling Kotlin's suspending functions from Objective-C and Swift in 1.4.0, and now we're improving it to keep up with a new Swift 5.5 feature – concurrency with `async` and `await` modifiers.

The Kotlin/Native compiler now emits the `_Nullable_result` attribute in the generated Objective-C headers for suspending functions with nullable return types. This makes it possible to call them from Swift as `async` functions with the proper nullability.

Note that this feature is experimental and can be affected in the future by changes in both Kotlin and Swift. For now, we're offering a preview of this feature that has certain limitations, and we are eager to hear what you think. Learn more about its current state and leave your feedback in this YouTrack issue.

Improved Swift/Objective-C mapping for objects and companion objects

Getting objects and companion objects can now be done in a way that is more intuitive for native iOS developers. For example, if you have the following objects in Kotlin:

```
object MyObject {
    val x = "Some value"
}

class MyClass {
    companion object {
        val x = "Some value"
    }
}
```

To access them in Swift, you can use the `shared` and `companion` properties:

```
MyObject.shared
MyObject.shared.x
MyClass.companion
MyClass.Companion.shared
```

Learn more about Swift/Objective-C interoperability.

Deprecation of linkage against DLLs without import libraries for MinGW targets

LLD is a linker from the LLVM project, which we plan to start using in Kotlin/Native for MinGW targets because of its benefits over the default ld.bfd – primarily its better performance.

However, the latest stable version of LLD doesn't support direct linkage against DLL for MinGW (Windows) targets. Such linkage requires using import libraries. Although they aren't needed with Kotlin/Native 1.5.30, we're adding a warning to inform you that such usage is incompatible with LLD that will become the default linker for MinGW in the future.

Please share your thoughts and concerns about the transition to the LLD linker in this YouTrack issue.

Kotlin Multiplatform

1.5.30 brings the following notable updates to Kotlin Multiplatform:

- Ability to use custom `cinterop` libraries in shared native code
- Support for XCFrameworks
- New default publishing setup for Android artifacts

Ability to use custom cinterop libraries in shared native code

Kotlin Multiplatform gives you an option to use platform-dependent interop libraries in shared source sets. Before 1.5.30, this worked only with platform libraries shipped with Kotlin/Native distribution. Starting from 1.5.30, you can use it with your custom `cinterop` libraries. To enable this feature, add the `kotlin.mpp.enableCInteropCommonization=true` property in your `gradle.properties`:

```
kotlin.mpp.enableGranularSourceSetsMetadata=true
kotlin.native.enableDependencyPropagation=false
kotlin.mpp.enableCInteropCommonization=true
```

Support for XCFrameworks

All Kotlin Multiplatform projects can now have XCFrameworks as an output format. Apple introduced XCFrameworks as a replacement for universal (fat) frameworks. With the help of XCFrameworks you:

- Can gather logic for all the target platforms and architectures in a single bundle.
- Don't need to remove all unnecessary architectures before publishing the application to the App Store.

XCFrameworks is useful if you want to use your Kotlin framework for devices and simulators on Apple M1.

To use XCFrameworks, update your `build.gradle(.kts)` script:

Kotlin

```kotlin
import org.jetbrains.kotlin.gradle.plugin.mpp.apple.XCFramework

plugins {
    kotlin("multiplatform")
}

kotlin {
    val xcf = XCFramework()

    ios {
        binaries.framework {
            baseName = "shared"
            xcf.add(this)
        }
    }
    watchos {
        binaries.framework {
            baseName = "shared"
            xcf.add(this)
        }
    }
    tvos {
        binaries.framework {
            baseName = "shared"
            xcf.add(this)
        }
    }
}
```

Groovy

```
import org.jetbrains.kotlin.gradle.plugin.mpp.apple.XCFrameworkConfig

plugins {
    id 'org.jetbrains.kotlin.multiplatform'
}

kotlin {
    def xcf = new XCFrameworkConfig(project)

    ios {
        binaries.framework {
            baseName = "shared"
            xcf.add(it)
        }
    }
    watchos {
        binaries.framework {
            baseName = "shared"
            xcf.add(it)
        }
    }
    tvos {
        binaries.framework {
            baseName = "shared"
            xcf.add(it)
        }
    }
}
```

When you declare XCFrameworks, these new Gradle tasks will be registered:

- `assembleXCFramework`
- `assembleDebugXCFramework` (additionally debug artifact that contains dSYMs)
- `assembleReleaseXCFramework`

Learn more about XCFrameworks in this WWDC video.

New default publishing setup for Android artifacts

Using the `maven-publish` Gradle plugin, you can publish your multiplatform library for the Android target by specifying Android variant names in the build script. The Kotlin Gradle plugin will generate publications automatically.

Before 1.5.30, the generated publication metadata included the build type attributes for every published Android variant, making it compatible only with the same build type used by the library consumer. Kotlin 1.5.30 introduces a new default publishing setup:

- If all Android variants that the project publishes have the same build type attribute, then the published variants won't have the build type attribute and will be compatible with any build type.
- If the published variants have different build type attributes, then only those with the `release` value will be published without the build type attribute. This makes the release variants compatible with any build type on the consumer side, while non-release variants will only be compatible with the matching consumer build types.

To opt-out and keep the build type attributes for all variants, you can set this Gradle property: `kotlin.android.buildTypeAttribute.keep=true`.

Kotlin/JS

Two major improvements are coming to Kotlin/JS with 1.5.30:

- JS IR compiler backend reaches Beta
- Better debugging experience for applications with the Kotlin/JS IR backend

JS IR compiler backend reaches Beta

The IR-based compiler backend for Kotlin/JS, which was introduced in 1.4.0 in Alpha, has reached Beta.

Previously, we published the migration guide for the JS IR backend to help you migrate your projects to the new backend. Now we would like to present the Kotlin/JS Inspection Pack IDE plugin, which displays the required changes directly in IntelliJ IDEA.

Better debugging experience for applications with the Kotlin/JS IR backend

Kotlin 1.5.30 brings JavaScript source map generation for the Kotlin/JS IR backend. This will improve the Kotlin/JS debugging experience when the IR backend is enabled, with full debugging support that includes breakpoints, stepping, and readable stack traces with proper source references.

Learn how to debug Kotlin/JS in the browser or IntelliJ IDEA.

Gradle

As a part of our mission to improve the Kotlin Gradle plugin user experience, we've implemented the following features:

- Support for Java toolchains, which includes an ability to specify a JDK home with the `UsesKotlinJavaToolchain` interface for older Gradle versions
- An easier way to explicitly specify the Kotlin daemon's JVM arguments

Support for Java toolchains

Gradle 6.7 introduced the "Java toolchains support" feature. Using this feature, you can:

- Run compilations, tests, and executables using JDKs and JREs that are different from the Gradle ones.
- Compile and test code with an unreleased language version.

With toolchains support, Gradle can autodetect local JDKs and install missing JDKs that Gradle requires for the build. Now Gradle itself can run on any JDK and still reuse the build cache feature.

The Kotlin Gradle plugin supports Java toolchains for Kotlin/JVM compilation tasks. A Java toolchain:

- Sets the `jdkHome` option available for JVM targets.

> The ability to set the `jdkHome` option directly has been deprecated.

- Sets the `kotlinOptions.jvmTarget` to the toolchain's JDK version if the user didn't set the `jvmTarget` option explicitly. If the toolchain is not configured, the `jvmTarget` field uses the default value. Learn more about JVM target compatibility.
- Affects which JDK `kapt` workers are running on.

Use the following code to set a toolchain. Replace the placeholder `<MAJOR_JDK_VERSION>` with the JDK version you would like to use:

Kotlin

```
kotlin {
    jvmToolchain {
        (this as JavaToolchainSpec).languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>))
// "8"
    }
}
```

Groovy

```
kotlin {
    jvmToolchain {
        languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)) // "8"
    }
}
```

Note that setting a toolchain via the `kotlin` extension will update the toolchain for Java compile tasks as well.

You can set a toolchain via the `java` extension, and Kotlin compilation tasks will use it:

```
java {
    toolchain {
        languageVersion.set(JavaLanguageVersion.of(<MAJOR_JDK_VERSION>)) // "8"
    }
}
```

For information about setting any JDK version for `KotlinCompile` tasks, look through the docs about setting the JDK version with the Task DSL.

For Gradle versions from 6.1 to 6.6, use the `UsesKotlinJavaToolchain` interface to set the JDK home.

Ability to specify JDK home with UsesKotlinJavaToolchain interface

All Kotlin tasks that support setting the JDK via `kotlinOptions` now implement the `UsesKotlinJavaToolchain` interface. To set the JDK home, put a path to your JDK and replace the `<JDK_VERSION>` placeholder:

Kotlin

```
project.tasks
    .withType<UsesKotlinJavaToolchain>()
    .configureEach {
        it.kotlinJavaToolchain.jdk.use(
            "/path/to/local/jdk",
            JavaVersion.<LOCAL_JDK_VERSION>
        )
    }
```

Groovy

```
project.tasks
    .withType(UsesKotlinJavaToolchain.class)
    .configureEach {
        it.kotlinJavaToolchain.jdk.use(
            '/path/to/local/jdk',
            JavaVersion.<LOCAL_JDK_VERSION>
        )
    }
```

Use the `UsesKotlinJavaToolchain` interface for Gradle versions from 6.1 to 6.6. Starting from Gradle 6.7, use the Java toolchains instead.

When using this feature, note that kapt task workers will only use process isolation mode, and the `kapt.workers.isolation` property will be ignored.

Easier way to explicitly specify Kotlin daemon JVM arguments

In Kotlin 1.5.30, there's a new logic for the Kotlin daemon's JVM arguments. Each of the options in the following list overrides the ones that came before it:

- If nothing is specified, the Kotlin daemon inherits arguments from the Gradle daemon (as before). For example, in the `gradle.properties` file:

  ```
  org.gradle.jvmargs=-Xmx1500m -Xms=500m
  ```

- If the Gradle daemon's JVM arguments have the `kotlin.daemon.jvm.options` system property, use it as before:

  ```
  org.gradle.jvmargs=-Dkotlin.daemon.jvm.options=-Xmx1500m -Xms=500m
  ```

- You can add the `kotlin.daemon.jvmargs` property in the `gradle.properties` file:

  ```
  kotlin.daemon.jvmargs=-Xmx1500m -Xms=500m
  ```

- You can specify arguments in the `kotlin` extension:

Kotlin

```
kotlin {
    kotlinDaemonJvmArgs = listOf("-Xmx486m", "-Xms256m", "-XX:+UseParallelGC")
}
```

Groovy

```
kotlin {
    kotlinDaemonJvmArgs = ["-Xmx486m", "-Xms256m", "-XX:+UseParallelGC"]
}
```

- You can specify arguments for a specific task:

Kotlin

```
tasks
    .matching { it.name == "compileKotlin" && it is CompileUsingKotlinDaemon }
    .configureEach {
        (this as CompileUsingKotlinDaemon).kotlinDaemonJvmArguments.set(listOf("-Xmx486m", "-
Xms256m", "-XX:+UseParallelGC"))
    }
```

Groovy

```
tasks
    .matching {
        it.name == "compileKotlin" && it instanceof CompileUsingKotlinDaemon
    }
    .configureEach {
        kotlinDaemonJvmArguments.set(["-Xmx1g", "-Xms512m"])
    }
```

In this case a new Kotlin daemon instance can start on task execution. Learn more about the Kotlin daemon's interactions with JVM arguments.

For more information about the Kotlin daemon, see the Kotlin daemon and using it with Gradle.

Standard library

Kotlin 1.5.30 is bringing improvements to the standard library's `Duration` and `Regex` APIs:

- Changing `Duration.toString()` output
- Parsing Duration from String
- Matching with Regex at a particular position
- Splitting Regex to a sequence

Changing Duration.toString() output

> The Duration API is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate hearing your feedback on it in YouTrack.

Before Kotlin 1.5.30, the `Duration.toString()` function would return a string representation of its argument expressed in the unit that yielded the most compact and readable number value. From now on, it will return a string value expressed as a combination of numeric components, each in its own unit. Each component is a number followed by the unit's abbreviated name: `d`, `h`, `m`, `s`. For example:

Example of function call	Previous output	Current output
Duration.days(45).toString()	`45.0d`	`45d`
Duration.days(1.5).toString()	`36.0h`	`1d 12h`
Duration.minutes(1230).toString()	`20.5h`	`20h 30m`
Duration.minutes(2415).toString()	`40.3h`	`1d 16h 15m`
Duration.minutes(920).toString()	`920m`	`15h 20m`
Duration.seconds(1.546).toString()	`1.55s`	`1.546s`
Duration.milliseconds(25.12).toString()	`25.1ms`	`25.12ms`

The way negative durations are represented has also been changed. A negative duration is prefixed with a minus sign (`-`), and if it consists of multiple components, it is surrounded with parentheses: `-12m` and `-(1h 30m)`.

Note that small durations of less than one second are represented as a single number with one of the subsecond units. For example, `ms` (milliseconds), `us` (microseconds), or `ns` (nanoseconds): `140.884ms`, `500us`, `24ns`. Scientific notation is no longer used to represent them.

If you want to express duration in a single unit, use the overloaded `Duration.toString(unit, decimals)` function.

> We recommend using `Duration.toIsoString()` in certain cases, including serialization and interchange. `Duration.toIsoString()` uses the stricter ISO-8601 format instead of `Duration.toString()`.

Parsing Duration from String

> The Duration API is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate hearing your feedback on it in this issue.

In Kotlin 1.5.30, there are new functions in the Duration API:

- `parse()`, which supports parsing the outputs of:
  - `toString()`.
  - `toString(unit, decimals)`.
  - `toIsoString()`.
- `parseIsoString()`, which only parses from the format produced by `toIsoString()`.
- `parseOrNull()` and `parseIsoStringOrNull()`, which behave like the functions above but return `null` instead of throwing `IllegalArgumentException` on invalid duration formats.

Here are some examples of `parse()` and `parseOrNull()` usages:

```
import kotlin.time.Duration
import kotlin.time.ExperimentalTime

@ExperimentalTime
fun main() {
    val isoFormatString = "PT1H30M"
    val defaultFormatString = "1h 30m"
    val singleUnitFormatString = "1.5h"
    val invalidFormatString = "1 hour 30 minutes"
    println(Duration.parse(isoFormatString)) // "1h 30m"
    println(Duration.parse(defaultFormatString)) // "1h 30m"
    println(Duration.parse(singleUnitFormatString)) // "1h 30m"
    //println(Duration.parse(invalidFormatString)) // throws exception
    println(Duration.parseOrNull(invalidFormatString)) // "null"
}
```

And here are some examples of `parseIsoString()` and `parseIsoStringOrNull()` usages:

```
import kotlin.time.Duration
import kotlin.time.ExperimentalTime

@ExperimentalTime
fun main() {
    val isoFormatString = "PT1H30M"
    val defaultFormatString = "1h 30m"
    println(Duration.parseIsoString(isoFormatString)) // "1h 30m"
    //println(Duration.parseIsoString(defaultFormatString)) // throws exception
    println(Duration.parseIsoStringOrNull(defaultFormatString)) // "null"
}
```

Matching with Regex at a particular position

> `Regex.matchAt()` and `Regex.matchesAt()` functions are Experimental. They may be dropped or changed at any time. Use them only for evaluation purposes. We would appreciate hearing your feedback on them in YouTrack.

The new `Regex.matchAt()` and `Regex.matchesAt()` functions provide a way to check whether a regex has an exact match at a particular position in a `String` or `CharSequence`.

`matchesAt()` returns a boolean result:

```
fun main(){
    val releaseText = "Kotlin 1.5.30 is released!"
    // regular expression: one digit, dot, one digit, dot, one or more digits
    val versionRegex = "\\d[.]\\d[.]\\d+".toRegex()
    println(versionRegex.matchesAt(releaseText, 0)) // "false"
    println(versionRegex.matchesAt(releaseText, 7)) // "true"
}
```

`matchAt()` returns the match if one is found or `null` if one isn't:

```
fun main(){
    val releaseText = "Kotlin 1.5.30 is released!"
    val versionRegex = "\\d[.]\\d[.]\\d+".toRegex()
    println(versionRegex.matchAt(releaseText, 0)) // "null"
    println(versionRegex.matchAt(releaseText, 7)?.value) // "1.5.30"
}
```

Splitting Regex to a sequence

> `Regex.splitToSequence()` and `CharSequence.splitToSequence(Regex)` functions are Experimental. They may be dropped or changed at any time. Use them only for evaluation purposes. We would appreciate hearing your feedback on them in YouTrack.

The new `Regex.splitToSequence()` function is a lazy counterpart of `split()`. It splits the string around matches of the given regex, but it returns the result as a Sequence so that all operations on this result are executed lazily.

```
fun main(){
    val colorsText = "green, red , brown&blue, orange, pink&green"
    val regex = "[,\\s]+".toRegex()
    val mixedColor = regex.splitToSequence(colorsText)
        .onEach { println(it) }
        .firstOrNull { it.contains('&') }
    println(mixedColor) // "brown&blue"
}
```

A similar function was also added to `CharSequence`:

```
val mixedColor = colorsText.splitToSequence(regex)
```

Serialization 1.3.0-RC

`kotlinx.serialization` 1.3.0-RC is here with new JSON serialization capabilities:

- Java IO streams serialization
- Property-level control over default values
- An option to exclude null values from serialization
- Custom class discriminators in polymorphic serialization

Learn more in the changelog.

What's new in Kotlin 1.5.20

Released: 24 June 2021

Kotlin 1.5.20 has fixes for issues discovered in the new features of 1.5.0, and it also includes various tooling improvements.

You can find an overview of the changes in the release blog post and this video:

Watch video online.

For information about the Kotlin release cycle, see Kotlin release process.

Kotlin/JVM

Kotlin 1.5.20 is receiving the following updates on the JVM platform:

- String concatenation via invokedynamic
- Support for JSpecify nullness annotations
- Support for calling Java's Lombok-generated methods within modules that have Kotlin and Java code

String concatenation via invokedynamic

Kotlin 1.5.20 compiles string concatenations into dynamic invocations (`invokedynamic`) on JVM 9+ targets, thereby keeping up with modern Java versions. More precisely, it uses `StringConcatFactory.makeConcatWithConstants()` for string concatenation.

To switch back to concatenation via `StringBuilder.append()` used in previous versions, add the compiler option `-Xstring-concat=inline` .

Learn how to add compiler options in Gradle, Maven, and the command-line compiler.

Support for JSpecify nullness annotations

The Kotlin compiler can read various types of nullability annotations to pass nullability information from Java to Kotlin. Version 1.5.20 introduces support for the JSpecify project, which includes the standard unified set of Java nullness annotations.

With JSpecify, you can provide more detailed nullability information to help Kotlin keep null-safety interoperating with Java. You can set default nullability for the declaration, package, or module scope, specify parametric nullability, and more. You can find more details about this in the JSpecify user guide.

Here is the example of how Kotlin can handle JSpecify annotations:

```
// JavaClass.java
import org.jspecify.nullness.*;

@NullMarked
public class JavaClass {
  public String notNullableString() { return ""; }
  public @Nullable String nullableString() { return ""; }
}
```

```
// Test.kt
fun kotlinFun() = with(JavaClass()) {
  notNullableString().length // OK
  nullableString().length    // Warning: receiver nullability mismatch
}
```

In 1.5.20, all nullability mismatches according to the JSpecify-provided nullability information are reported as warnings. Use the `-Xjspecify-annotations=strict` and `-Xtype-enhancement-improvements-strict-mode` compiler options to enable strict mode (with error reporting) when working with JSpecify. Please note that the JSpecify project is under active development. Its API and implementation can change significantly at any time.

Learn more about null-safety and platform types.

Support for calling Java's Lombok-generated methods within modules that have Kotlin and Java code

> The Lombok compiler plugin is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

Kotlin 1.5.20 introduces an experimental Lombok compiler plugin. This plugin makes it possible to generate and use Java's Lombok declarations within modules that have Kotlin and Java code. Lombok annotations work only in Java sources and are ignored if you use them in Kotlin code.

The plugin supports the following annotations:

- `@Getter`, `@Setter`
- `@NoArgsConstructor`, `@RequiredArgsConstructor`, and `@AllArgsConstructor`
- `@Data`
- `@With`
- `@Value`

We're continuing to work on this plugin. To find out the detailed current state, visit the Lombok compiler plugin's README.

Currently, we don't have plans to support the `@Builder` annotation. However, we can consider this if you vote for `@Builder` in YouTrack.

Learn how to configure the Lombok compiler plugin.

Kotlin/Native

Kotlin/Native 1.5.20 offers a preview of the new feature and the tooling improvements:

- Opt-in export of KDoc comments to generated Objective-C headers
- Compiler bug fixes
- Improved performance of Array.copyInto() inside one array

Opt-in export of KDoc comments to generated Objective-C headers

> The ability to export KDoc comments to generated Objective-C headers is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

You can now set the Kotlin/Native compiler to export the documentation comments (KDoc) from Kotlin code to the Objective-C frameworks generated from it, making them visible to the frameworks' consumers.

For example, the following Kotlin code with KDoc:

```
/**
 * Prints the sum of the arguments.
 * Properly handles the case when the sum doesn't fit in 32-bit integer.
 */
fun printSum(a: Int, b: Int) = println(a.toLong() + b)
```

produces the following Objective-C headers:

```
/**
 * Prints the sum of the arguments.
 * Properly handles the case when the sum doesn't fit in 32-bit integer.
 */
+ (void)printSumA:(int32_t)a b:(int32_t)b __attribute__((swift_name("printSum(a:b:)")));
```

This also works well with Swift.

To try out this ability to export KDoc comments to Objective-C headers, use the `-Xexport-kdoc` compiler option. Add the following lines to `build.gradle(.kts)` of the Gradle projects you want to export comments from:

Kotlin

```
kotlin {
    targets.withType<org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget> {
        compilations.get("main").kotlinOptions.freeCompilerArgs += "-Xexport-kdoc"
    }
}
```

Groovy

```
kotlin {
    targets.withType(org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget) {
        compilations.get("main").kotlinOptions.freeCompilerArgs += "-Xexport-kdoc"
    }
}
```

We would be very grateful if you would share your feedback with us using this YouTrack ticket.

Compiler bug fixes

The Kotlin/Native compiler has received multiple bug fixes in 1.5.20. You can find the complete list in the changelog.

There is an important bug fix that affects compatibility: in previous versions, string constants that contained incorrect UTF surrogate pairs were losing their values during compilation. Now such values are preserved. Application developers can safely update to 1.5.20 – nothing will break. However, libraries compiled with 1.5.20 are incompatible with earlier compiler versions. See this YouTrack issue for details.

Improved performance of Array.copyInto() inside one array

We've improved the way `Array.copyInto()` works when its source and destination are the same array. Now such operations finish up to 20 times faster (depending on the number of objects being copied) due to memory management optimizations for this use case.

Kotlin/JS

With 1.5.20, we're publishing a guide that will help you migrate your projects to the new IR-based backend for Kotlin/JS.

Migration guide for the JS IR backend

The new migration guide for the JS IR backend identifies issues you may encounter during migration and provides solutions for them. If you find any issues that aren't covered in the guide, please report them to our issue tracker.

Gradle

Kotlin 1.5.20 introduces the following features that can improve the Gradle experience:

- Caching for annotation processors classloaders in kapt
- Deprecation of the `kotlin.parallel.tasks.in.project` build property

Caching for annotation processors' classloaders in kapt

> Caching for annotation processors' classloaders in kapt is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

There is now a new experimental feature that makes it possible to cache the classloaders of annotation processors in kapt. This feature can increase the speed of kapt for consecutive Gradle runs.

To enable this feature, use the following properties in your `gradle.properties` file:

```
# positive value will enable caching
# use the same value as the number of modules that use kapt
kapt.classloaders.cache.size=5

# disable for caching to work
kapt.include.compile.classpath=false
```

Learn more about kapt.

Deprecation of the kotlin.parallel.tasks.in.project build property

With this release, Kotlin parallel compilation is controlled by the Gradle parallel execution flag `--parallel`. Using this flag, Gradle executes tasks concurrently, increasing the speed of compiling tasks and utilizing the resources more efficiently.

You no longer need to use the `kotlin.parallel.tasks.in.project` property. This property has been deprecated and will be removed in the next major release.

Standard library

Kotlin 1.5.20 changes the platform-specific implementations of several functions for working with characters and as a result brings unification across platforms:

- Support for all Unicode digits in Char.digitToInt() for Kotlin/Native and Kotlin/JS.
- Unification of Char.isLowerCase()/isUpperCase() implementations across platforms.

Support for all Unicode digits in Char.digitToInt() in Kotlin/Native and Kotlin/JS

`Char.digitToInt()` returns the numeric value of the decimal digit that the character represents. Before 1.5.20, the function supported all Unicode digit characters only for Kotlin/JVM: implementations on the Native and JS platforms supported only ASCII digits.

From now, both with Kotlin/Native and Kotlin/JS, you can call `Char.digitToInt()` on any Unicode digit character and get its numeric representation.

```
fun main() {
    val ten = '\u0661'.digitToInt() + '\u0039'.digitToInt() // ARABIC-INDIC DIGIT ONE + DIGIT NINE
    println(ten)
}
```

Unification of Char.isLowerCase()/isUpperCase() implementations across platforms

The functions `Char.isUpperCase()` and `Char.isLowerCase()` return a boolean value depending on the case of the character. For Kotlin/JVM, the implementation checks both the `General_Category` and the `Other_Uppercase` / `Other_Lowercase` Unicode properties.

Prior to 1.5.20, implementations for other platforms worked differently and considered only the general category. In 1.5.20, implementations are unified across platforms and use both properties to determine the character case:

```
fun main() {
    val latinCapitalA = 'A' // has "Lu" general category
    val circledLatinCapitalA = 'Ⓐ' // has "Other_Uppercase" property
    println(latinCapitalA.isUpperCase() && circledLatinCapitalA.isUpperCase())
}
```

What's new in Kotlin 1.5.0

Released: 5 May 2021

Kotlin 1.5.0 introduces new language features, stable IR-based JVM compiler backend, performance improvements, and evolutionary changes such as stabilizing experimental features and deprecating outdated ones.

You can also find an overview of the changes in the release blog post.

> For information about the Kotlin release cycle, see Kotlin release process.

Language features

Kotlin 1.5.0 brings stable versions of the new language features presented for preview in 1.4.30:

- JVM records support
- Sealed interfaces and sealed class improvements
- Inline classes

Detailed descriptions of these features are available in this blog post and the corresponding pages of Kotlin documentation.

JVM records support

Java is evolving fast, and to make sure Kotlin remains interoperable with it, we've introduced support for one of its latest features – record classes.

Kotlin's support for JVM records includes bidirectional interoperability:

- In Kotlin code, you can use Java record classes like you would use typical classes with properties.
- To use a Kotlin class as a record in Java code, make it a `data` class and mark it with the `@JvmRecord` annotation.

```
@JvmRecord
data class User(val name: String, val age: Int)
```

Learn more about using JVM records in Kotlin.

Watch video online.

Sealed interfaces

Kotlin interfaces can now have the `sealed` modifier, which works on interfaces in the same way it works on classes: all implementations of a sealed interface are known at compile time.

```
sealed interface Polygon
```

You can rely on that fact, for example, to write exhaustive `when` expressions.

```
fun draw(polygon: Polygon) = when (polygon) {
    is Rectangle -> // ...
    is Triangle -> // ...
    // else is not needed - all possible implementations are covered
}
```

Additionally, sealed interfaces enable more flexible restricted class hierarchies because a class can directly inherit more than one sealed interface.

```
class FilledRectangle: Polygon, Fillable
```

Learn more about sealed interfaces.

Watch video online.

Package-wide sealed class hierarchies

Sealed classes can now have subclasses in all files of the same compilation unit and the same package. Previously, all subclasses had to appear in the same file.

Direct subclasses may be top-level or nested inside any number of other named classes, named interfaces, or named objects.

The subclasses of a sealed class must have a name that is properly qualified – they cannot be local or anonymous objects.

Learn more about sealed class hierarchies.

Inline classes

Inline classes are a subset of value-based classes that only hold values. You can use them as wrappers for a value of a certain type without the additional overhead that comes from using memory allocations.

Inline classes can be declared with the `value` modifier before the name of the class:

```
value class Password(val s: String)
```

The JVM backend also requires a special `@JvmInline` annotation:

```
@JvmInline
value class Password(val s: String)
```

The `inline` modifier is now deprecated with a warning.

Learn more about inline classes.

Watch video online.

Kotlin/JVM

Kotlin/JVM has received a number of improvements, both internal and user-facing. Here are the most notable among them:

- Stable JVM IR backend
- New default JVM target: 1.8
- SAM adapters via invokedynamic
- Lambdas via invokedynamic
- Deprecation of @JvmDefault and old Xjvm-default modes
- Improvements to handling nullability annotations

Stable JVM IR backend

The IR-based backend for the Kotlin/JVM compiler is now Stable and enabled by default.

Starting from Kotlin 1.4.0, early versions of the IR-based backend were available for preview, and it has now become the default for language version `1.5`. The old backend is still used by default for earlier language versions.

You can find more details about the benefits of the IR backend and its future development in this blog post.

If you need to use the old backend in Kotlin 1.5.0, you can add the following lines to the project's configuration file:

- In Gradle:

Kotlin

```
tasks.withType<org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile> {
  kotlinOptions.useOldBackend = true
}
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile) {
 kotlinOptions.useOldBackend = true
}
```

- In Maven:

```
<configuration>
    <args>
        <arg>-Xuse-old-backend</arg>
    </args>
</configuration>
```

New default JVM target: 1.8

The default target version for Kotlin/JVM compilations is now `1.8`. The `1.6` target is deprecated.

If you need a build for JVM 1.6, you can still switch to this target. Learn how:

- in Gradle
- in Maven
- in the command-line compiler

SAM adapters via invokedynamic

Kotlin 1.5.0 now uses dynamic invocations (`invokedynamic`) for compiling SAM (Single Abstract Method) conversions:

- Over any expression if the SAM type is a Java interface
- Over lambda if the SAM type is a Kotlin functional interface

The new implementation uses `LambdaMetafactory.metafactory()` and auxiliary wrapper classes are no longer generated during compilation. This decreases the size of the application's JAR, which improves the JVM startup performance.

To roll back to the old implementation scheme based on anonymous class generation, add the compiler option `-Xsam-conversions=class`.

Learn how to add compiler options in Gradle, Maven, and the command-line compiler.

Lambdas via invokedynamic

> Compiling plain Kotlin lambdas into invokedynamic is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below), and you should use it only for evaluation purposes. We would appreciate hearing your feedback on it in YouTrack.

Kotlin 1.5.0 is introducing experimental support for compiling plain Kotlin lambdas (which are not converted to an instance of a functional interface) into dynamic invocations (`invokedynamic`). The implementation produces lighter binaries by using `LambdaMetafactory.metafactory()`, which effectively generates the necessary classes at runtime. Currently, it has three limitations compared to ordinary lambda compilation:

- A lambda compiled into invokedynamic is not serializable.
- Calling `toString()` on such a lambda produces a less readable string representation.
- Experimental `reflect` API does not support lambdas created with `LambdaMetafactory`.

To try this feature, add the `-Xlambdas=indy` compiler option. We would be grateful if you could share your feedback on it using this YouTrack ticket.

Learn how to add compiler options in Gradle, Maven, and command-line compiler.

Deprecation of @JvmDefault and old Xjvm-default modes

Prior to Kotlin 1.4.0, there was the `@JvmDefault` annotation along with `-Xjvm-default=enable` and `-Xjvm-default=compatibility` modes. They served to create the JVM default method for any particular non-abstract member in the Kotlin interface.

In Kotlin 1.4.0, we introduced the new `Xjvm-default` modes, which switch on default method generation for the whole project.

In Kotlin 1.5.0, we are deprecating `@JvmDefault` and the old Xjvm-default modes: `-Xjvm-default=enable` and `-Xjvm-default=compatibility`.

Learn more about default methods in the Java interop.

Improvements to handling nullability annotations

Kotlin supports handling type nullability information from Java with nullability annotations. Kotlin 1.5.0 introduces a number of improvements for the feature:

- It reads nullability annotations on type arguments in compiled Java libraries that are used as dependencies.
- It supports nullability annotations with the `TYPE_USE` target for:
  - Arrays

- Varargs
- Fields
- Type parameters and their bounds
- Type arguments of base classes and interfaces

- If a nullability annotation has multiple targets applicable to a type, and one of these targets is `TYPE_USE`, then `TYPE_USE` is preferred. For example, the method signature `@Nullable String[] f()` becomes `fun f(): Array<String?>!` if `@Nullable` supports both `TYPE_USE` and `METHOD` as targets.

For these newly supported cases, using the wrong type nullability when calling Java from Kotlin produces warnings. Use the `-Xtype-enhancement-improvements-strict-mode` compiler option to enable strict mode for these cases (with error reporting).

Learn more about null-safety and platform types.

Kotlin/Native

Kotlin/Native is now more performant and stable. The notable changes are:

- Performance improvements
- Deactivation of the memory leak checker

Performance improvements

In 1.5.0, Kotlin/Native is receiving a set of performance improvements that speed up both compilation and execution.

Compiler caches are now supported in debug mode for `linuxX64` (only on Linux hosts) and `iosArm64` targets. With compiler caches enabled, most debug compilations complete much faster, except for the first one. Measurements showed about a 200% speed increase on our test projects.

To use compiler caches for new targets, opt in by adding the following lines to the project's `gradle.properties`:

- For `linuxX64`: `kotlin.native.cacheKind.linuxX64=static`
- For `iosArm64`: `kotlin.native.cacheKind.iosArm64=static`

If you encounter any issues after enabling the compiler caches, please report them to our issue tracker YouTrack.

Other improvements speed up the execution of Kotlin/Native code:

- Trivial property accessors are inlined.
- `trimIndent()` on string literals is evaluated during the compilation.

Deactivation of the memory leak checker

The built-in Kotlin/Native memory leak checker has been disabled by default.

It was initially designed for internal use, and it is able to find leaks only in a limited number of cases, not all of them. Moreover, it later turned out to have issues that can cause application crashes. So we've decided to turn off the memory leak checker.

The memory leak checker can still be useful for certain cases, for example, unit testing. For these cases, you can enable it by adding the following line of code:

```
Platform.isMemoryLeakCheckerActive = true
```

Note that enabling the checker for the application runtime is not recommended.

Kotlin/JS

Kotlin/JS is receiving evolutionary changes in 1.5.0. We're continuing our work on moving the JS IR compiler backend towards stable and shipping other updates:

- Upgrade of webpack to version 5
- Frameworks and libraries for the IR compiler

Upgrade to webpack 5

The Kotlin/JS Gradle plugin now uses webpack 5 for browser targets instead of webpack 4. This is a major webpack upgrade that brings incompatible changes. If you're using a custom webpack configuration, be sure to check the webpack 5 release notes.

Learn more about bundling Kotlin/JS projects with webpack.

Frameworks and libraries for the IR compiler

The Kotlin/JS IR compiler is in Alpha. It may change incompatibly and require manual migration in the future. We would appreciate your feedback on it in YouTrack.

Along with working on the IR-based backend for Kotlin/JS compiler, we encourage and help library authors to build their projects in `both` mode. This means they are able to produce artifacts for both Kotlin/JS compilers, therefore growing the ecosystem for the new compiler.

Many well-known frameworks and libraries are already available for the IR backend: KVision, fritz2, doodle, and others. If you're using them in your project, you can already build it with the IR backend and see the benefits it brings.

If you're writing your own library, compile it in the 'both' mode so that your clients can also use it with the new compiler.

Kotlin Multiplatform

In Kotlin 1.5.0, choosing a testing dependency for each platform has been simplified and it is now done automatically by the Gradle plugin.

A new API for getting a char category is now available in multiplatform projects.

Standard library

The standard library has received a range of changes and improvements, from stabilizing experimental parts to adding new features:

- Stable unsigned integer types
- Stable locale-agnostic API for uppercase/lowercase text

- Stable Char-to-integer conversion API
- Stable Path API
- Floored division and the mod operator
- Duration API changes
- New API for getting a char category now available in multiplatform code
- New collections function firstNotNullOf()
- Strict version of String?.toBoolean()

You can learn more about the standard library changes in this blog post.

Watch video online.

Stable unsigned integer types

The `UInt`, `ULong`, `UByte`, `UShort` unsigned integer types are now Stable. The same goes for operations on these types, ranges, and progressions of them. Unsigned arrays and operations on them remain in Beta.

Learn more about unsigned integer types.

Stable locale-agnostic API for upper/lowercasing text

This release brings a new locale-agnostic API for uppercase/lowercase text conversion. It provides an alternative to the `toLowerCase()`, `toUpperCase()`, `capitalize()`, and `decapitalize()` API functions, which are locale-sensitive. The new API helps you avoid errors due to different locale settings.

Kotlin 1.5.0 provides the following fully Stable alternatives:

- For `String` functions:

Earlier versions	1.5.0 alternative
`String.toUpperCase()`	`String.uppercase()`
`String.toLowerCase()`	`String.lowercase()`
`String.capitalize()`	`String.replaceFirstChar { it.uppercase() }`
`String.decapitalize()`	`String.replaceFirstChar { it.lowercase() }`

- For `Char` functions:

Earlier versions	1.5.0 alternative
`Char.toUpperCase()`	`Char.uppercaseChar(): Char` `Char.uppercase(): String`

Earlier versions	1.5.0 alternative
`Char.toLowerCase()`	`Char.lowercaseChar(): Char` `Char.lowercase(): String`
`Char.toTitleCase()`	`Char.titlecaseChar(): Char` `Char.titlecase(): String`

For Kotlin/JVM, there are also overloaded `uppercase()`, `lowercase()`, and `titlecase()` functions with an explicit `Locale` parameter.

The old API functions are marked as deprecated and will be removed in a future release.

See the full list of changes to the text processing functions in KEEP.

Stable char-to-integer conversion API

Starting from Kotlin 1.5.0, new char-to-code and char-to-digit conversion functions are Stable. These functions replace the current API functions, which were often confused with the similar string-to-Int conversion.

The new API removes this naming confusion, making the code behavior more transparent and unambiguous.

This release introduces `Char` conversions that are divided into the following sets of clearly named functions:

- Functions to get the integer code of `Char` and to construct `Char` from the given code:

```
fun Char(code: Int): Char
fun Char(code: UShort): Char
val Char.code: Int
```

- Functions to convert `Char` to the numeric value of the digit it represents:

```
fun Char.digitToInt(radix: Int): Int
fun Char.digitToIntOrNull(radix: Int): Int?
```

- An extension function for `Int` to convert the non-negative single digit it represents to the corresponding `Char` representation:

```
fun Int.digitToChar(radix: Int): Char
```

The old conversion APIs, including `Number.toChar()` with its implementations (all except `Int.toChar()`) and `Char` extensions for conversion to a numeric type, like `Char.toInt()`, are now deprecated.

Learn more about the char-to-integer conversion API in KEEP.

Stable Path API

The experimental Path API with extensions for `java.nio.file.Path` is now Stable.

```
// list files in a directory
val kotlinFiles: List<Path> = Path("/home/user").listDirectoryEntries("*.kt")
```

Learn more about the Path API.

Floored division and the mod operator

New operations for modular arithmetics have been added to the standard library:

- `floorDiv()` returns the result of floored division. It is available for integer types.
- `mod()` returns the remainder of floored division (*modulus*). It is available for all numeric types.

These operations look quite similar to the existing division of integers and rem() function (or the `%` operator), but they work differently on negative numbers:

- `a.floorDiv(b)` differs from a regular `/` in that `floorDiv` rounds the result down (towards the lesser integer), whereas `/` truncates the result to the integer closer to 0.
- `a.mod(b)` is the difference between `a` and `a.floorDiv(b) * b`. It's either zero or has the same sign as `b`, while `a % b` can have a different one.

```
fun main() {
    println("Floored division -5/3: ${(-5).floorDiv(3)}")
    println( "Modulus: ${(-5).mod(3)}")

    println("Truncated division -5/3: ${-5 / 3}")
    println( "Remainder: ${-5 % 3}")
}
```

Duration API changes

> The Duration API is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate hearing your feedback on it in YouTrack.

There is an experimental Duration class for representing duration amounts in different time units. In 1.5.0, the Duration API has received the following changes:

- Internal value representation now uses `Long` instead of `Double` to provide better precision.
- There is a new API for conversion to a particular time unit in `Long`. It comes to replace the old API, which operates with `Double` values and is now deprecated. For example, `Duration.inWholeMinutes` returns the value of the duration expressed as `Long` and replaces `Duration.inMinutes`.
- There are new companion functions for constructing a `Duration` from a number. For example, `Duration.seconds(Int)` creates a `Duration` object representing an integer number of seconds. Old extension properties like `Int.seconds` are now deprecated.

```
import kotlin.time.Duration
import kotlin.time.ExperimentalTime

@ExperimentalTime
fun main() {
    val duration = Duration.milliseconds(120000)
    println("There are ${duration.inWholeSeconds} seconds in ${duration.inWholeMinutes} minutes")
}
```

New API for getting a char category now available in multiplatform code

Kotlin 1.5.0 introduces the new API for getting a character's category according to Unicode in multiplatform projects. Several functions are now available in all the platforms and in the common code.

Functions for checking whether a char is a letter or a digit:

- `Char.isDigit()`
- `Char.isLetter()`
- `Char.isLetterOrDigit()`

```
fun main() {
    val chars = listOf('a', '1', '+')
    val (letterOrDigitList, notLetterOrDigitList) = chars.partition { it.isLetterOrDigit() }
    println(letterOrDigitList) // [a, 1]
    println(notLetterOrDigitList) // [+]
}
```

Functions for checking the case of a char:

- `Char.isLowerCase()`
- `Char.isUpperCase()`
- `Char.isTitleCase()`

```
fun main() {
    val chars = listOf('Dž', 'Lj', 'Nj', 'Dz', '1', 'A', 'a', '+')
    val (titleCases, notTitleCases) = chars.partition { it.isTitleCase() }
    println(titleCases) // [Dž, Lj, Nj, Dz]
    println(notTitleCases) // [1, A, a, +]
}
```

Some other functions:

- `Char.isDefined()`
- `Char.isISOControl()`

The property `Char.category` and its return type enum class `CharCategory`, which indicates a char's general category according to Unicode, are now also available in multiplatform projects.

Learn more about characters.

New collections function firstNotNullOf()

The new `firstNotNullOf()` and `firstNotNullOfOrNull()` functions combine `mapNotNull()` with `first()` or `firstOrNull()`. They map the original collection with the custom selector function and return the first non-null value. If there is no such value, `firstNotNullOf()` throws an exception, and `firstNotNullOfOrNull()` returns null.

```
fun main() {
    val data = listOf("Kotlin", "1.5")
    println(data.firstNotNullOf(String::toDoubleOrNull))
    println(data.firstNotNullOfOrNull(String::toIntOrNull))
}
```

Strict version of String?.toBoolean()

Two new functions introduce case-sensitive strict versions of the existing String?.toBoolean():

- `String.toBooleanStrict()` throws an exception for all inputs except the literals `true` and `false`.
- `String.toBooleanStrictOrNull()` returns null for all inputs except the literals `true` and `false`.

```
fun main() {
    println("true".toBooleanStrict())
    println("1".toBooleanStrictOrNull())
    // println("1".toBooleanStrict()) // Exception
}
```

kotlin-test library

The kotlin-test library introduces some new features:

- Simplified test dependencies usage in multiplatform projects
- Automatic selection of a testing framework for Kotlin/JVM source sets
- Assertion function updates

Simplified test dependencies usage in multiplatform projects

Now you can use the `kotlin-test` dependency to add dependencies for testing in the `commonTest` source set, and the Gradle plugin will infer the corresponding platform dependencies for each test source set:

- `kotlin-test-junit` for JVM source sets, see automatic choice of a testing framework for Kotlin/JVM source sets
- `kotlin-test-js` for Kotlin/JS source sets
- `kotlin-test-common` and `kotlin-test-annotations-common` for common source sets
- No extra artifact for Kotlin/Native source sets

Additionally, you can use the `kotlin-test` dependency in any shared or platform-specific source set.

An existing kotlin-test setup with explicit dependencies will continue to work both in Gradle and in Maven.

Learn more about setting dependencies on test libraries.

Automatic selection of a testing framework for Kotlin/JVM source sets

The Gradle plugin now chooses and adds a dependency on a testing framework automatically. All you need to do is add the dependency `kotlin-test` in the common source set.

Gradle uses JUnit 4 by default. Therefore, the `kotlin("test")` dependency resolves to the variant for JUnit 4, namely `kotlin-test-junit`:

Kotlin

```
kotlin {
    sourceSets {
        val commonTest by getting {
            dependencies {
                implementation(kotlin("test")) // This brings the dependency
                                               // on JUnit 4 transitively
            }
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        commonTest {
            dependencies {
                implementation kotlin("test") // This brings the dependency
                                              // on JUnit 4 transitively
            }
        }
    }
}
```

You can choose JUnit 5 or TestNG by calling `useJUnitPlatform()` or `useTestNG()` in the test task:

```
tasks {
    test {
        // enable TestNG support
        useTestNG()
        // or
        // enable JUnit Platform (a.k.a. JUnit 5) support
        useJUnitPlatform()
    }
}
```

You can disable automatic testing framework selection by adding the line `kotlin.test.infer.jvm.variant=false` to the project's `gradle.properties`.

Learn more about setting dependencies on test libraries.

Assertion function updates

This release brings new assertion functions and improves the existing ones.

The `kotlin-test` library now has the following features:

- **Checking the type of a value**

  You can use the new `assertIs<T>` and `assertIsNot<T>` to check the type of a value:

```
@Test
fun testFunction() {
    val s: Any = "test"
    assertIs<String>(s)  // throws AssertionError mentioning the actual type of s if the assertion
fails
    // can now print s.length because of contract in assertIs
    println("${s.length}")
}
```

Because of type erasure, this assert function only checks whether the `value` is of the `List` type in the following example and doesn't check whether it's a list of the particular `String` element type: `assertIs<List<String>>(value)`.

- **Comparing the container content for arrays, sequences, and arbitrary iterables**

  There is a new set of overloaded `assertContentEquals()` functions for comparing content for different collections that don't implement structural equality:

```
@Test
fun test() {
    val expectedArray = arrayOf(1, 2, 3)
    val actualArray = Array(3) { it + 1 }
    assertContentEquals(expectedArray, actualArray)
}
```

- **New overloads to `assertEquals()` and `assertNotEquals()` for `Double` and `Float` numbers**

  There are new overloads for the `assertEquals()` function that make it possible to compare two `Double` or `Float` numbers with absolute precision. The precision value is specified as the third parameter of the function:

```
@Test
fun test() {
    val x = sin(PI)

    // precision parameter
    val tolerance = 0.000001

    assertEquals(0.0, x, tolerance)
}
```

- **New functions for checking the content of collections and elements**

  You can now check whether the collection or element contains something with the `assertContains()` function. You can use it with Kotlin collections and elements that have the `contains()` operator, such as `IntRange`, `String`, and others:

```
@Test
fun test() {
    val sampleList = listOf<String>("sample", "sample2")
    val sampleString = "sample"
    assertContains(sampleList, sampleString)  // element in collection
    assertContains(sampleString, "amp")       // substring in string
}
```

- **`assertTrue()`, `assertFalse()`, `expect()` functions are now inline**

  From now on, you can use these as inline functions, so it's possible to call suspend functions inside a lambda expression:

```
@Test
fun test() = runBlocking<Unit> {
    val deferred = async { "Kotlin is nice" }
    assertTrue("Kotlin substring should be present") {
        deferred.await() .contains("Kotlin")
    }
}
```

kotlinx libraries

Along with Kotlin 1.5.0, we are releasing new versions of the kotlinx libraries:

- `kotlinx.coroutines` 1.5.0-RC
- `kotlinx.serialization` 1.2.1
- `kotlinx-datetime` 0.2.0

Coroutines 1.5.0-RC

`kotlinx.coroutines` 1.5.0-RC is here with:

- New channels API
- Stable reactive integrations
- And more

Starting with Kotlin 1.5.0, experimental coroutines are disabled and the `-Xcoroutines=experimental` flag is no longer supported.

Learn more in the changelog and the `kotlinx.coroutines` 1.5.0 release blog post.

Watch video online.

Serialization 1.2.1

`kotlinx.serialization` 1.2.1 is here with:

- Improvements to JSON serialization performance
- Support for multiple names in JSON serialization
- Experimental .proto schema generation from `@Serializable` classes
- And more

Learn more in the changelog and the `kotlinx.serialization` 1.2.1 release blog post.

Watch video online.

dateTime 0.2.0

`kotlinx-datetime` 0.2.0 is here with:

- `@Serializable` Datetime objects
- Normalized API of `DateTimePeriod` and `DatePeriod`

- And more

Learn more in the changelog and the `kotlinx-datetime` 0.2.0 release blog post.

Migrating to Kotlin 1.5.0

IntelliJ IDEA and Android Studio will suggest updating the Kotlin plugin to 1.5.0 once it is available.

To migrate existing projects to Kotlin 1.5.0, just change the Kotlin version to `1.5.0` and re-import your Gradle or Maven project. Learn how to update to Kotlin 1.5.0.

To start a new project with Kotlin 1.5.0, update the Kotlin plugin and run the Project Wizard from **File** | **New** | **Project**.

The new command-line compiler is available for downloading on the GitHub release page.

Kotlin 1.5.0 is a feature release and therefore can bring incompatible changes to the language. Find the detailed list of such changes in the Compatibility Guide for Kotlin 1.5.

Compatibility guide for Kotlin 1.5.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.4 to Kotlin 1.5.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language and stdlib

Forbid spread operator in signature-polymorphic calls

Issue: KT-35226

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw the use of spread operator (*) on signature-polymorphic calls

Deprecation cycle:

- < 1.5: introduce warning for the problematic operator at call-site
- >= 1.5: raise this warning to an error, `-XXLanguage:-ProhibitSpreadOnSignaturePolymorphicCall` can be used to temporarily revert to pre-1.5 behavior

Forbid non-abstract classes containing abstract members invisible from that classes (internal/package-private)

Issue: KT-27825

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw non-abstract classes containing abstract members invisible from that classes (internal/package-private)

Deprecation cycle:

- < 1.5: introduce warning for the problematic classes
- >= 1.5: raise this warning to an error, `-XXLanguage:-ProhibitInvisibleAbstractMethodsInSuperclasses` can be used to temporarily revert to pre-1.5 behavior

Forbid using array based on non-reified type parameters as reified type arguments on JVM

Issue: KT-31227

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw using array based on non-reified type parameters as reified type arguments on JVM

Deprecation cycle:

- < 1.5: introduce warning for the problematic calls
- >= 1.5: raise this warning to an error, `-XXLanguage:-ProhibitNonReifiedArraysAsReifiedTypeArguments` can be used to temporarily revert to pre-1.5 behavior

Forbid secondary enum class constructors which do not delegate to the primary constructor

Issue: KT-35870

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw secondary enum class constructors which do not delegate to the primary constructor

Deprecation cycle:

- < 1.5: introduce warning for the problematic constructors
- >= 1.5: raise this warning to an error, `-XXLanguage:-RequiredPrimaryConstructorDelegationCallInEnums` can be used to temporarily revert to pre-1.5 behavior

Forbid exposing anonymous types from private inline functions

Issue: KT-33917

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw exposing anonymous types from private inline functions

Deprecation cycle:

- < 1.5: introduce warning for the problematic constructors
- >= 1.5: raise this warning to an error, `-XXLanguage:-ApproximateAnonymousReturnTypesInPrivateInlineFunctions` can be used to temporarily revert to pre-1.5 behavior

Forbid passing non-spread arrays after arguments with SAM-conversion

Issue: KT-35224

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw passing non-spread arrays after arguments with SAM-conversion

Deprecation cycle:

- 1.3.70: introduce warning for the problematic calls
- >= 1.5: raise this warning to an error, `-XXLanguage:-ProhibitVarargAsArrayAfterSamArgument` can be used to temporarily revert to pre-1.5 behavior

Support special semantics for underscore-named catch block parameters

Issue: KT-31567

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw references to the underscore symbol (`_`) that is used to omit parameter name of an exception in the catch block

Deprecation cycle:

- 1.4.20: introduce warning for the problematic references
- >= 1.5: raise this warning to an error, `-XXLanguage:-ForbidReferencingToUnderscoreNamedParameterOfCatchBlock` can be used to temporarily revert to pre-1.5 behavior

Change implementation strategy of SAM conversion from anonymous class-based to invokedynamic

Issue: KT-44912

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Since Kotlin 1.5, implementation strategy of SAM (single abstract method) conversion will be changed from generating an anonymous class to using the `invokedynamic` JVM instruction

Deprecation cycle:

- 1.5: change implementation strategy of SAM conversion, `-Xsam-conversions=class` can be used to revert implementation scheme to the one that used before

Performance issues with the JVM IR-based backend

Issue: KT-48233

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin 1.5 uses the IR-based backend for the Kotlin/JVM compiler by default. The old backend is still used by default for earlier language versions.

You might encounter some performance degradation issues using the new compiler in Kotlin 1.5. We are working on fixing such cases.

Deprecation cycle:

- < 1.5: by default, the old JVM backend is used
- >= 1.5: by default, the IR-based backend is used. If you need to use the old backend in Kotlin 1.5, add the following lines to the project's configuration file to temporarily revert to pre-1.5 behavior:

In Gradle:

Kotlin

```
tasks.withType<org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile> {
  kotlinOptions.useOldBackend = true
}
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile) {
  kotlinOptions.useOldBackend = true
}
```

In Maven:

```
<configuration>
    <args>
        <arg>-Xuse-old-backend</arg>
    </args>
</configuration>
```

Support for this flag will be removed in one of the future releases.

New field sorting in the JVM IR-based backend

Issue: KT-46378

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Since version 1.5, Kotlin uses the IR-based backend that sorts JVM bytecode differently: it generates fields declared in the constructor before fields declared in the body, while it's vice versa for the old backend. The new sorting may change the behavior of programs that use serialization frameworks that depend on the field order, such as Java serialization.

Deprecation cycle:

- < 1.5: by default, the old JVM backend is used. It has fields declared in the body before fields declared in the constructor.
- >= 1.5: by default, the new IR-based backend is used. Fields declared in the constructor are generated before fields declared in the body. As a workaround, you can temporarily switch to the old backend in Kotlin 1.5. To do that, add the following lines to the project's configuration file:

In Gradle:

Kotlin

```
tasks.withType<org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile> {
  kotlinOptions.useOldBackend = true
}
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile) {
  kotlinOptions.useOldBackend = true
}
```

In Maven:

```
<configuration>
    <args>
        <arg>-Xuse-old-backend</arg>
    </args>
</configuration>
```

Support for this flag will be removed in one of the future releases.

Generate nullability assertion for delegated properties with a generic call in the delegate expression

Issue: KT-44304

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Since Kotlin 1.5, the Kotlin compiler will emit nullability assertions for delegated properties with a generic call in the delegate expression

Deprecation cycle:

- 1.5: emit nullability assertion for delegated properties (see details in the issue), `-Xuse-old-backend` or `-language-version 1.4` can be used to temporarily revert to pre-1.5 behavior

Turn warnings into errors for calls with type parameters annotated by @OnlyInputTypes

Issue: KT-45861

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.5 will outlaw calls like `contains`, `indexOf`, and `assertEquals` with senseless arguments to improve type safety

Deprecation cycle:

- 1.4.0: introduce warning for the problematic constructors
- >= 1.5: raise this warning to an error, `-XXLanguage:-StrictOnlyInputTypesChecks` can be used to temporarily revert to pre-1.5 behavior

Use the correct order of arguments execution in calls with named vararg

Issue: KT-17691

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin 1.5 will change the order of arguments execution in calls with named vararg

Deprecation cycle:

- < 1.5: introduce warning for the problematic constructors
- >= 1.5: raise this warning to an error, `-XXLanguage:-UseCorrectExecutionOrderForVarargArguments` can be used to temporarily revert to pre-1.5 behavior

Use default value of the parameter in operator functional calls

Issue: KT-42064

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin 1.5 will use default value of the parameter in operator calls

Deprecation cycle:

- < 1.5: old behavior (see details in the issue)
- >= 1.5: behavior changed, `-XXLanguage:-JvmIrEnabledByDefault` can be used to temporarily revert to pre-1.5 behavior

Produce empty reversed progressions in for loops if regular progression is also empty

Issue: KT-42533

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Kotlin 1.5 will produce empty reversed progressions in for loops if regular progression is also empty

Deprecation cycle:

- < 1.5: old behavior (see details in the issue)
- >= 1.5: behavior changed, `-XXLanguage:-JvmIrEnabledByDefault` can be used to temporarily revert to pre-1.5 behavior

Straighten Char-to-code and Char-to-digit conversions out

Issue: KT-23451

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Since Kotlin 1.5, conversions of Char to number types will be deprecated

Deprecation cycle:

- 1.5: deprecate `Char.toInt()/toShort()/toLong()/toByte()/toDouble()/toFloat()` and the reverse functions like `Long.toChar()`, and propose replacement

Inconsistent case-insensitive comparison of characters in kotlin.text functions

Issue: KT-45496

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: Since Kotlin 1.5, `Char.equals` will be improved in case-insensitive case by first comparing whether the uppercase variants of characters are equal, then whether the lowercase variants of those uppercase variants (as opposed to the characters themselves) are equal

Deprecation cycle:

- < 1.5: old behavior (see details in the issue)
- 1.5: change behavior for `Char.equals` function

Remove default locale-sensitive case conversion API

Issue: KT-43023

Component: kotlin-stdlib

Incompatible change type: source

Short summary: Since Kotlin 1.5, default locale-sensitive case conversion functions like `String.toUpperCase()` will be deprecated

Deprecation cycle:

- 1.5: deprecate case conversions functions with the default locale (see details in the issue), and propose replacement

Gradually change the return type of collection min and max functions to non-nullable

Issue: KT-38854

Component: kotlin-stdlib (JVM)

Incompatible change type: source

Short summary: return type of collection `min` and `max` functions will be changed to non-nullable in 1.6

Deprecation cycle:

- 1.4: introduce `...OrNull` functions as synonyms and deprecate the affected API (see details in the issue)
- 1.5.0: raise the deprecation level of the affected API to error
- >=1.6: reintroduce the affected API but with non-nullable return type

Raise the deprecation level of conversions of floating-point types to Short and Byte

Issue: KT-30360

Component: kotlin-stdlib (JVM)

Incompatible change type: source

Short summary: conversions of floating-point types to `Short` and `Byte` deprecated in Kotlin 1.4 with `WARNING` level will cause errors since Kotlin 1.5.0.

Deprecation cycle:

- 1.4: deprecate `Double.toShort()/toByte()` and `Float.toShort()/toByte()` and propose replacement
- 1.5.0: raise the deprecation level to error

Tools

Do not mix several JVM variants of kotlin-test in a single project

Issue: KT-40225

Component: Gradle

Incompatible change type: behavioral

Short summary: several mutually exclusive `kotlin-test` variants for different testing frameworks could have been in a project if one of them is brought by a transitive dependency. From 1.5.0, Gradle won't allow having mutually exclusive `kotlin-test` variants for different testing frameworks.

Deprecation cycle:

- < 1.5: having several mutually exclusive `kotlin-test` variants for different testing frameworks is allowed
- >= 1.5: behavior changed,
  Gradle throws an exception like "Cannot select module with conflict on capability...". Possible solutions:
  - use the same `kotlin-test` variant and the corresponding testing framework as the transitive dependency brings.
  - find another variant of the dependency that doesn't bring the `kotlin-test` variant transitively, so you can use the testing framework you would like to use.
  - find another variant of the dependency that brings another `kotlin-test` variant transitively, which uses the same testing framework you would like to use.
  - exclude the testing framework that is brought transitively. The following example is for excluding JUnit 4:

    ```
    configurations {
        testImplementation.get().exclude("org.jetbrains.kotlin", "kotlin-test-junit")
    }
    ```

    After excluding the testing framework, test your application. If it stopped working, rollback excluding changes, use the same testing framework as the library does, and exclude your testing framework.

What's new in Kotlin 1.4.30

Released: 3 February 2021

Kotlin 1.4.30 offers preview versions of new language features, promotes the new IR backend of the Kotlin/JVM compiler to Beta, and ships various performance and functional improvements.

You can also learn about new features in this blog post.

For information about the Kotlin release cycle, see Kotlin release process.

Language features

Kotlin 1.5.0 is going to deliver new language features – JVM records support, sealed interfaces, and Stable inline classes. In Kotlin 1.4.30, you can try these features and improvements in preview mode. We would be very grateful if you share your feedback with us in the corresponding YouTrack tickets, as that will allow us to address it before the release of 1.5.0.

- JVM records support
- Sealed interfaces and sealed class improvements
- Improved inline classes

To enable these language features and improvements in preview mode, you need to opt in by adding specific compiler options. See the sections below for details.

Learn more about the new features preview in this blog post.

JVM records support

> The JVM records feature is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

The JDK 16 release includes plans to stabilize a new Java class type called record. To provide all the benefits of Kotlin and maintain its interoperability with Java, Kotlin is introducing experimental record class support.

You can use record classes that are declared in Java just like classes with properties in Kotlin. No additional steps are required.

Starting with 1.4.30, you can declare the record class in Kotlin using the `@JvmRecord` annotation for a data class:

```
@JvmRecord
data class User(val name: String, val age: Int)
```

To try the preview version of JVM records, add the compiler options `-Xjvm-enable-preview` and `-language-version 1.5`.

We're continuing to work on JVM records support, and we would be very grateful if you would share your feedback with us using this YouTrack ticket.

Learn more about implementation, restrictions, and the syntax in KEEP.

Sealed interfaces

> Sealed interfaces are Experimental. They may be dropped or changed at any time. Opt-in is required (see the details below), and you should use them only for evaluation purposes. We would appreciate your feedback on them in YouTrack.

In Kotlin 1.4.30, we're shipping the prototype of *sealed interfaces*. They complement sealed classes and make it possible to build more flexible restricted class hierarchies.

They can serve as "internal" interfaces that cannot be implemented outside the same module. You can rely on that fact, for example, to write exhaustive `when` expressions.

```
sealed interface Polygon

class Rectangle(): Polygon
class Triangle(): Polygon

// when() is exhaustive: no other polygon implementations can appear
// after the module is compiled
fun draw(polygon: Polygon) = when (polygon) {
    is Rectangle -> // ...
    is Triangle -> // ...
}
```

Another use-case: with sealed interfaces, you can inherit a class from two or more sealed superclasses.

```
sealed interface Fillable {
   fun fill()
}
sealed interface Polygon {
   val vertices: List<Point>
}

class Rectangle(override val vertices: List<Point>): Fillable, Polygon {
   override fun fill() { /*...*/ }
}
```

To try the preview version of sealed interfaces, add the compiler option `-language-version 1.5`. Once you switch to this version, you'll be able to use the `sealed` modifier on interfaces. We would be very grateful if you would share your feedback with us using this YouTrack ticket.

Learn more about sealed interfaces.

Package-wide sealed class hierarchies

Package-wide hierarchies of sealed classes are Experimental. They may be dropped or changed at any time. Opt-in is required (see the details below), and you should use them only for evaluation purposes. We would appreciate your feedback on them in YouTrack.

Sealed classes can now form more flexible hierarchies. They can have subclasses in all files of the same compilation unit and the same package. Previously, all subclasses had to appear in the same file.

Direct subclasses may be top-level or nested inside any number of other named classes, named interfaces, or named objects. The subclasses of a sealed class must have a name that is properly qualified – they cannot be local nor anonymous objects.

To try package-wide hierarchies of sealed classes, add the compiler option `-language-version 1.5`. We would be very grateful if you would share your feedback with us using this YouTrack ticket.

Learn more about package-wide hierarchies of sealed classes.

Improved inline classes

Inline value classes are in Beta. They are almost stable, but migration steps may be required in the future. We'll do our best to minimize any changes you have to make. We would appreciate your feedback on the inline classes feature in YouTrack.

Kotlin 1.4.30 promotes inline classes to Beta and brings the following features and improvements to them:

- Since inline classes are value-based, you can define them using the `value` modifier. The `inline` and `value` modifiers are now equivalent to each other. In future Kotlin versions, we're planning to deprecate the `inline` modifier.

  From now on, Kotlin requires the `@JvmInline` annotation before a class declaration for the JVM backend:

  ```
  inline class Name(private val s: String)

  value class Name(private val s: String)

  // For JVM backends
  @JvmInline
  value class Name(private val s: String)
  ```

- Inline classes can have `init` blocks. You can add code to be executed right after the class is instantiated:

  ```
  @JvmInline
  value class Negative(val x: Int) {
    init {
        require(x < 0) { }
    }
  }
  ```

- Calling functions with inline classes from Java code: before Kotlin 1.4.30, you couldn't call functions that accept inline classes from Java because of mangling. From now on, you can disable mangling manually. To call such functions from Java code, you should add the `@JvmName` annotation before the function declaration:

  ```
  inline class UInt(val x: Int)

  fun compute(x: Int) { }

  @JvmName("computeUInt")
  fun compute(x: UInt) { }
  ```

- In this release, we've changed the mangling scheme for functions to fix the incorrect behavior. These changes led to ABI changes.

  Starting with 1.4.30, the Kotlin compiler uses a new mangling scheme by default. Use the `-Xuse-14-inline-classes-mangling-scheme` compiler flag to force the compiler to use the old 1.4.0 mangling scheme and preserve binary compatibility.

Kotlin 1.4.30 promotes inline classes to Beta and we are planning to make them Stable in future releases. We'd be very grateful if you would share your feedback with us using this YouTrack ticket.

To try the preview version of inline classes, add the compiler option `-Xinline-classes` or `-language-version 1.5`.

Learn more about the mangling algorithm in KEEP.

Learn more about inline classes.

Kotlin/JVM

JVM IR compiler backend reaches Beta

The IR-based compiler backend for Kotlin/JVM, which was presented in 1.4.0 in Alpha, has reached Beta. This is the last pre-stable level before the IR backend becomes the default for the Kotlin/JVM compiler.

We're now dropping the restriction on consuming binaries produced by the IR compiler. Previously, you could use code compiled by the new JVM IR backend only if you had enabled the new backend. Starting from 1.4.30, there is no such limitation, so you can use the new backend to build components for third-party use, such as libraries. Try the Beta version of the new backend and share your feedback in our issue tracker.

To enable the new JVM IR backend, add the following lines to the project's configuration file:

- In Gradle:

Kotlin

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile::class) {
  kotlinOptions.useIR = true
}
```

Groovy

```
tasks.withType(org.jetbrains.kotlin.gradle.dsl.KotlinJvmCompile) {
  kotlinOptions.useIR = true
}
```

- In Maven:

```
<configuration>
    <args>
        <arg>-Xuse-ir</arg>
    </args>
</configuration>
```

Learn more about the changes that the JVM IR backend brings in this blog post.

Kotlin/Native

Performance improvements

Kotlin/Native has received a variety of performance improvements in 1.4.30, which has resulted in faster compilation times. For example, the time required to rebuild the framework in the Networking and data storage with Kotlin Multiplatform Mobile sample has decreased from 9.5 seconds (in 1.4.10) to 4.5 seconds (in 1.4.30).

Apple watchOS 64-bit simulator target

The x86 simulator target has been deprecated for watchOS since version 7.0. To keep up with the latest watchOS versions, Kotlin/Native has the new target `watchosX64` for running the simulator on 64-bit architecture.

Support for Xcode 12.2 libraries

We have added support for the new libraries delivered with Xcode 12.2. You can now use them from Kotlin code.

Kotlin/JS

Lazy initialization of top-level properties

> Lazy initialization of top-level properties is Experimental. It may be dropped or changed at any time. Opt-in is required (see the details below), and you should use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

The IR backend for Kotlin/JS is receiving a prototype implementation of lazy initialization for top-level properties. This reduces the need to initialize all top-level properties when the application starts, and it should significantly improve application start-up times.

We'll keep working on the lazy initialization, and we ask you to try the current prototype and share your thoughts and results in this YouTrack ticket or the `#javascript` channel in the official Kotlin Slack (get an invite here).

To use the lazy initialization, add the `-Xir-property-lazy-initialization` compiler option when compiling the code with the JS IR compiler.

Gradle project improvements

Support the Gradle configuration cache

Starting with 1.4.30, the Kotlin Gradle plugin supports the configuration cache feature. It speeds up the build process: once you run the command, Gradle executes the configuration phase and calculates the task graph. Gradle caches the result and reuses it for subsequent builds.

To start using this feature, you can use the Gradle command or set up the IntelliJ based IDE.

Standard library

Locale-agnostic API for upper/lowercasing text

> The locale-agnostic API feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

This release introduces the experimental locale-agnostic API for changing the case of strings and characters. The current `toLowerCase()`, `toUpperCase()`, `capitalize()`, `decapitalize()` API functions are locale-sensitive. This means that different platform locale settings can affect code behavior. For example, in the Turkish locale, when the string "kotlin" is converted using `toUpperCase`, the result is "KOTLİN", not "KOTLIN".

```
// current API
println("Needs to be capitalized".toUpperCase()) // NEEDS TO BE CAPITALIZED

// new API
println("Needs to be capitalized".uppercase()) // NEEDS TO BE CAPITALIZED
```

Kotlin 1.4.30 provides the following alternatives:

- For `String` functions:

Earlier versions	1.4.30 alternative
`String.toUpperCase()`	`String.uppercase()`
`String.toLowerCase()`	`String.lowercase()`
`String.capitalize()`	`String.replaceFirstChar { it.uppercase() }`
`String.decapitalize()`	`String.replaceFirstChar { it.lowercase() }`

- For `Char` functions:

Earlier versions	1.4.30 alternative
`Char.toUpperCase()`	`Char.uppercaseChar(): Char` `Char.uppercase(): String`
`Char.toLowerCase()`	`Char.lowercaseChar(): Char` `Char.lowercase(): String`
`Char.toTitleCase()`	`Char.titlecaseChar(): Char` `Char.titlecase(): String`

For Kotlin/JVM, there are also overloaded `uppercase()`, `lowercase()`, and `titlecase()` functions with an explicit `Locale` parameter.

See the full list of changes to the text processing functions in KEEP.

Clear Char-to-code and Char-to-digit conversions

The unambiguous API for the `Char` conversion feature is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We would appreciate your feedback on it in YouTrack.

The current `Char` to numbers conversion functions, which return UTF-16 codes expressed in different numeric types, are often confused with the similar String-to-Int conversion, which returns the numeric value of a string:

```
"4".toInt() // returns 4
'4'.toInt() // returns 52
// and there was no common function that would return the numeric value 4 for Char '4'
```

To avoid this confusion we've decided to separate `Char` conversions into two following sets of clearly named functions:

- Functions to get the integer code of `Char` and to construct `Char` from the given code:

```
fun Char(code: Int): Char
fun Char(code: UShort): Char
val Char.code: Int
```

- Functions to convert `Char` to the numeric value of the digit it represents:

```
fun Char.digitToInt(radix: Int): Int
fun Char.digitToIntOrNull(radix: Int): Int?
```

- An extension function for `Int` to convert the non-negative single digit it represents to the corresponding `Char` representation:

```
fun Int.digitToChar(radix: Int): Char
```

See more details in KEEP.

Serialization updates

Along with Kotlin 1.4.30, we are releasing `kotlinx.serialization` 1.1.0-RC, which includes some new features:

- Inline classes serialization support
- Unsigned primitive type serialization support

Inline classes serialization support

Starting with Kotlin 1.4.30, you can make inline classes serializable:

```
@Serializable
inline class Color(val rgb: Int)
```

The feature requires the new 1.4.30 IR compiler.

The serialization framework does not box serializable inline classes when they are used in other serializable classes.

Learn more in the `kotlinx.serialization` docs.

Unsigned primitive type serialization support

Starting from 1.4.30, you can use standard JSON serializers of kotlinx.serialization for unsigned primitive types: `UInt`, `ULong`, `UByte`, and `UShort`:

```
@Serializable
class Counter(val counted: UByte, val description: String)
fun main() {
    val counted = 239.toUByte()
    println(Json.encodeToString(Counter(counted, "tries")))
}
```

Learn more in the `kotlinx.serialization` docs.

What's new in Kotlin 1.4.20

Released: 23 November 2020

Kotlin 1.4.20 offers a number of new experimental features and provides fixes and improvements for existing features, including those added in 1.4.0.

You can also learn about new features with more examples in this blog post.

For information about the Kotlin release cycle, see Kotlin release process.

Kotlin/JVM

Improvements of Kotlin/JVM are intended to keep it up with the features of modern Java versions:

- Java 15 target
- invokedynamic string concatenation

Java 15 target

Now Java 15 is available as a Kotlin/JVM target.

invokedynamic string concatenation

`invokedynamic` string concatenation is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

Kotlin 1.4.20 can compile string concatenations into dynamic invocations on JVM 9+ targets, therefore improving the performance.

Currently, this feature is experimental and covers the following cases:

- `String.plus` in the operator (`a + b`), explicit (`a.plus(b)`), and reference (`(a::plus)(b)`) form.
- `toString` on inline and data classes.
- string templates except for ones with a single non-constant argument (see KT-42457).

To enable `invokedynamic` string concatenation, add the `-Xstring-concat` compiler option with one of the following values:

- `indy-with-constants` to perform `invokedynamic` concatenation on strings with StringConcatFactory.makeConcatWithConstants().
- `indy` to perform `invokedynamic` concatenation on strings with StringConcatFactory.makeConcat().
- `inline` to switch back to the classic concatenation via `StringBuilder.append()`.

Kotlin/JS

Kotlin/JS keeps evolving fast, and in 1.4.20 you can find a number experimental features and improvements:

- Gradle DSL changes
- New Wizard templates
- Ignoring compilation errors with IR compiler

Gradle DSL changes

The Gradle DSL for Kotlin/JS receives a number of updates which simplify project setup and customization. This includes webpack configuration adjustments, modifications to the auto-generated `package.json` file, and improved control over transitive dependencies.

Single point for webpack configuration

A new configuration block `commonWebpackConfig` is available for the browser target. Inside it, you can adjust common settings from a single point, instead of having to duplicate configurations for the `webpackTask`, `runTask`, and `testTask`.

To enable CSS support by default for all three tasks, add the following snippet in the `build.gradle(.kts)` of your project:

```
browser {
    commonWebpackConfig {
        cssSupport.enabled = true
    }
    binaries.executable()
}
```

Learn more about configuring webpack bundling.

package.json customization from Gradle

For more control over your Kotlin/JS package management and distribution, you can now add properties to the project file `package.json` via the Gradle DSL.

To add custom fields to your `package.json`, use the `customField` function in the compilation's `packageJson` block:

```
kotlin {
    js(BOTH) {
        compilations["main"].packageJson {
            customField("hello", mapOf("one" to 1, "two" to 2))
        }
    }
}
```

Learn more about `package.json` customization.

Selective yarn dependency resolutions

> Support for selective yarn dependency resolutions is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

Kotlin 1.4.20 provides a way of configuring Yarn's selective dependency resolutions - the mechanism for overriding dependencies of the packages you depend on.

You can use it through the `YarnRootExtension` inside the `YarnPlugin` in Gradle. To affect the resolved version of a package for your project, use the `resolution` function passing in the package name selector (as specified by Yarn) and the version to which it should resolve.

```
rootProject.plugins.withType<YarnPlugin> {
    rootProject.the<YarnRootExtension>().apply {
        resolution("react", "16.0.0")
        resolution("processor/decamelize", "3.0.0")
    }
}
```

Here, *all* of your npm dependencies which require `react` will receive version `16.0.0`, and `processor` will receive its dependency `decamelize` as version `3.0.0`.

Disabling granular workspaces

> Disabling granular workspaces is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

To speed up build times, the Kotlin/JS Gradle plugin only installs the dependencies which are required for a particular Gradle task. For example, the `webpack-dev-server` package is only installed when you execute one of the `*Run` tasks, and not when you execute the assemble task. Such behavior can potentially bring problems when you run multiple Gradle processes in parallel. When the dependency requirements clash, the two installations of npm packages can cause errors.

To resolve this issue, Kotlin 1.4.20 includes an option to disable these so-called *granular workspaces*. This feature is currently available through the `YarnRootExtension` inside the `YarnPlugin` in Gradle. To use it, add the following snippet to your `build.gradle.kts` file:

```
rootProject.plugins.withType<YarnPlugin> {
    rootProject.the<YarnRootExtension>().disableGranularWorkspaces()
}
```

New Wizard templates

To give you more convenient ways to customize your project during creation, the project wizard for Kotlin comes with new templates for Kotlin/JS applications:

- **Browser Application** - a minimal Kotlin/JS Gradle project that runs in the browser.

- **React Application** - a React app that uses the appropriate `kotlin-wrappers`. It provides options to enable integrations for style-sheets, navigational components, or state containers.
- **Node.js Application** - a minimal project for running in a Node.js runtime. It comes with the option to directly include the experimental `kotlinx-nodejs` package.

Ignoring compilation errors with IR compiler

> *Ignore compilation errors* mode is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

The IR compiler for Kotlin/JS comes with a new experimental mode - *compilation with errors*. In this mode, you can run you code even if it contains errors, for example, if you want to try certain things it when the whole application is not ready yet.

There are two tolerance policies for this mode:

- `SEMANTIC`: the compiler will accept code which is syntactically correct, but doesn't make sense semantically, such as `val x: String = 3`.
- `SYNTAX`: the compiler will accept any code, even if it contains syntax errors.

To allow compilation with errors, add the `-Xerror-tolerance-policy=` compiler option with one of the values listed above.

Learn more about Kotlin/JS IR compiler.

Kotlin/Native

Kotlin/Native's priorities in 1.4.20 are performance and polishing existing features. These are the notable improvements:

- Escape analysis
- Performance improvements and bug fixes
- Opt-in wrapping of Objective-C exceptions
- CocoaPods plugin improvements
- Support for Xcode 12 libraries

Escape analysis

> The escape analysis mechanism is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

Kotlin/Native receives a prototype of the new escape analysis mechanism. It improves the runtime performance by allocating certain objects on the stack instead of the heap. This mechanism shows a 10% average performance increase on our benchmarks, and we continue improving it so that it speeds up the program even more.

The escape analysis runs in a separate compilation phase for the release builds (with the `-opt` compiler option).

If you want to disable the escape analysis phase, use the `-Xdisable-phases=EscapeAnalysis` compiler option.

Performance improvements and bug fixes

Kotlin/Native receives performance improvements and bug fixes in various components, including the ones added in 1.4.0, for example, the code sharing mechanism.

Opt-in wrapping of Objective-C exceptions

> The Objective-C exception wrapping mechanism is Experimental. It may be dropped or changed at any time. Opt-in is required (see details below). Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

Kotlin/Native now can handle exceptions thrown from Objective-C code in runtime to avoid program crashes.

You can opt in to wrap `NSException`'s into Kotlin exceptions of type `ForeignException`. They hold the references to the original `NSException`'s. This lets you get the information about the root cause and handle it properly.

To enable wrapping of Objective-C exceptions, specify the `-Xforeign-exception-mode objc-wrap` option in the `cinterop` call or add `foreignExceptionMode = objc-wrap` property to `.def` file. If you use CocoaPods integration, specify the option in the `pod {}` build script block of a dependency like this:

```
pod("foo") {
    extraOpts = listOf("-Xforeign-exception-mode", "objc-wrap")
}
```

The default behavior remains unchanged: the program terminates when an exception is thrown from the Objective-C code.

CocoaPods plugin improvements

Kotlin 1.4.20 continues the set of improvements in CocoaPods integration. Namely, you can try the following new features:

- Improved task execution
- Extended DSL
- Updated integration with Xcode

Improved task execution

CocoaPods plugin gets an improved task execution flow. For example, if you add a new CocoaPods dependency, existing dependencies are not rebuilt. Adding an extra target also doesn't affect rebuilding dependencies for existing ones.

Extended DSL

The DSL of adding CocoaPods dependencies to your Kotlin project receives new capabilites.

In addition to local Pods and Pods from the CocoaPods repository, you can add dependencies on the following types of libraries:

- A library from a custom spec repository.
- A remote library from a Git repository.
- A library from an archive (also available by arbitrary HTTP address).
- A static library.
- A library with custom cinterop options.

Learn more about adding CocoaPods dependencies in Kotlin projects. Find examples in the Kotlin with CocoaPods sample.

Updated integration with Xcode

To work correctly with Xcode, Kotlin requires some Podfile changes:

- If your Kotlin Pod has any Git, HTTP, or specRepo Pod dependency, you should also specify it in the Podfile.
- When you add a library from the custom spec, you also should specify the location of specs at the beginning of your Podfile.

Now integration errors have a detailed description in IDEA. So if you have problems with your Podfile, you will immediately know how to fix them.

Learn more about creating Kotlin pods.

Support for Xcode 12 libraries

We have added support for new libraries delivered with Xcode 12. Now you can use them from the Kotlin code.

Kotlin Multiplatform

Updated structure of multiplatform library publications

Starting from Kotlin 1.4.20, there is no longer a separate metadata publication. Metadata artifacts are now included in the *root* publication which stands for the whole library and is automatically resolved to the appropriate platform-specific artifacts when added as a dependency to the common source set.

Learn more about publishing a multiplatform library.

Compatibility with earlier versions

This change of structure breaks the compatibility between projects with hierarchical project structure. If a multiplatform project and a library it depends on both have the hierarchical project structure, then you need to update them to Kotlin 1.4.20 or higher simultaneously. Libraries published with Kotlin 1.4.20 are not available for using from project published with earlier versions.

Projects and libraries without the hierarchical project structure remain compatible.

Standard library

The standard library of Kotlin 1.4.20 offers new extensions for working with files and a better performance.

- Extensions for java.nio.file.Path

- Improved String.replace function performance

Extensions for java.nio.file.Path

> Extensions for `java.nio.file.Path` are Experimental. They may be dropped or changed at any time. Opt-in is required (see details below). Use them only for evaluation purposes. We appreciate your feedback on them in YouTrack.

Now the standard library provides experimental extensions for `java.nio.file.Path`. Working with the modern JVM file API in an idiomatic Kotlin way is now similar to working with `java.io.File` extensions from the `kotlin.io` package.

```
// construct path with the div (/) operator
val baseDir = Path("/base")
val subDir = baseDir / "subdirectory"

// list files in a directory
val kotlinFiles: List<Path> = Path("/home/user").listDirectoryEntries("*.kt")
```

The extensions are available in the `kotlin.io.path` package in the `kotlin-stdlib-jdk7` module. To use the extensions, opt-in to the experimental annotation `@ExperimentalPathApi`.

Improved String.replace function performance

The new implementation of `String.replace()` speeds up the function execution. The case-sensitive variant uses a manual replacement loop based on `indexOf`, while the case-insensitive one uses regular expression matching.

Kotlin Android Extensions

In 1.4.20 the Kotlin Android Extensions plugin becomes deprecated and `Parcelable` implementation generator moves to a separate plugin.

- Deprecation of synthetic views
- New plugin for Parcelable implementation generator

Deprecation of synthetic views

Synthetic views were presented in the Kotlin Android Extensions plugin a while ago to simplify the interaction with UI elements and reduce boilerplate. Now Google offers a native mechanism that does the same - Android Jetpack's view bindings, and we're deprecating synthetic views in favor of those.

We extract the Parcelable implementations generator from `kotlin-android-extensions` and start the deprecation cycle for the rest of it - synthetic views. For now, they will keep working with a deprecation warning. In the future, you'll need to switch your project to another solution. Here are the guidelines that will help you migrate your Android project from synthetics to view bindings.

New plugin for Parcelable implementation generator

The `Parcelable` implementation generator is now available in the new `kotlin-parcelize` plugin. Apply this plugin instead of `kotlin-android-extensions`.

> `kotlin-parcelize` and `kotlin-android-extensions` can't be applied together in one module.

The `@Parcelize` annotation is moved to the `kotlinx.parcelize` package.

Learn more about `Parcelable` implementation generator in the Android documentation.

What's new in Kotlin 1.4.0

Released: 17 August 2020

In Kotlin 1.4.0, we ship a number of improvements in all of its components, with the focus on quality and performance. Below you will find the list of the most important changes in Kotlin 1.4.0.

> For information about the Kotlin release cycle, see Kotlin release process.

Language features and improvements

Kotlin 1.4.0 comes with a variety of different language features and improvements. They include:

- SAM conversions for Kotlin interfaces
- Explicit API mode for library authors
- Mixing named and positional arguments
- Trailing comma
- Callable reference improvements
- break and continue inside when included in loops

SAM conversions for Kotlin interfaces

Before Kotlin 1.4.0, you could apply SAM (Single Abstract Method) conversions only when working with Java methods and Java interfaces from Kotlin. From now on, you can use SAM conversions for Kotlin interfaces as well. To do so, mark a Kotlin interface explicitly as functional with the `fun` modifier.

SAM conversion applies if you pass a lambda as an argument when an interface with only one single abstract method is expected as a parameter. In this case, the compiler automatically converts the lambda to an instance of the class that implements the abstract member function.

```kotlin
fun interface IntPredicate {
    fun accept(i: Int): Boolean
}

val isEven = IntPredicate { it % 2 == 0 }

fun main() {
    println("Is 7 even? - ${isEven.accept(7)}")
}
```

Learn more about Kotlin functional interfaces and SAM conversions.

Explicit API mode for library authors

Kotlin compiler offers *explicit API mode* for library authors. In this mode, the compiler performs additional checks that help make the library's API clearer and more consistent. It adds the following requirements for declarations exposed to the library's public API:

- Visibility modifiers are required for declarations if the default visibility exposes them to the public API. This helps ensure that no declarations are exposed to the public API unintentionally.
- Explicit type specifications are required for properties and functions that are exposed to the public API. This guarantees that API users are aware of the types of API members they use.

Depending on your configuration, these explicit APIs can produce errors (*strict* mode) or warnings (*warning* mode). Certain kinds of declarations are excluded from such checks for the sake of readability and common sense:

- primary constructors
- properties of data classes
- property getters and setters
- `override` methods

Explicit API mode analyzes only the production sources of a module.

To compile your module in the explicit API mode, add the following lines to your Gradle build script:

Kotlin

```kotlin
kotlin {
    // for strict mode
    explicitApi()
    // or
    explicitApi = ExplicitApiMode.Strict

    // for warning mode
    explicitApiWarning()
    // or
    explicitApi = ExplicitApiMode.Warning
}
```

Groovy

```
kotlin {
    // for strict mode
    explicitApi()
    // or
    explicitApi = 'strict'

    // for warning mode
    explicitApiWarning()
    // or
    explicitApi = 'warning'
}
```

When using the command-line compiler, switch to explicit API mode by adding the `-Xexplicit-api` compiler option with the value `strict` or `warning`.

```
-Xexplicit-api={strict|warning}
```

Find more details about the explicit API mode in the KEEP.

Mixing named and positional arguments

In Kotlin 1.3, when you called a function with named arguments, you had to place all the arguments without names (positional arguments) before the first named argument. For example, you could call `f(1, y = 2)`, but you couldn't call `f(x = 1, 2)`.

It was really annoying when all the arguments were in their correct positions but you wanted to specify a name for one argument in the middle. It was especially helpful for making absolutely clear which attribute a boolean or `null` value belongs to.

In Kotlin 1.4, there is no such limitation – you can now specify a name for an argument in the middle of a set of positional arguments. Moreover, you can mix positional and named arguments any way you like, as long as they remain in the correct order.

```
fun reformat(
    str: String,
    uppercaseFirstLetter: Boolean = true,
    wordSeparator: Char = ' '
) {
    // ...
}

//Function call with a named argument in the middle
reformat("This is a String!", uppercaseFirstLetter = false , '-')
```

Trailing comma

With Kotlin 1.4 you can now add a trailing comma in enumerations such as argument and parameter lists, `when` entries, and components of destructuring declarations. With a trailing comma, you can add new items and change their order without adding or removing commas.

This is especially helpful if you use multi-line syntax for parameters or values. After adding a trailing comma, you can then easily swap lines with parameters or values.

```
fun reformat(
    str: String,
    uppercaseFirstLetter: Boolean = true,
    wordSeparator: Character = ' ', //trailing comma
) {
    // ...
}
```

```
val colors = listOf(
    "red",
    "green",
    "blue", //trailing comma
)
```

Callable reference improvements

Kotlin 1.4 supports more cases for using callable references:

- References to functions that include parameters with default values
- Function references in `Unit`-returning functions
- References that adapt based on the number of arguments in a function
- Suspend conversion on callable references

References to functions that include parameters with default values

Now you can use callable references to functions including parameters with default values. If the callable reference to the function `foo` takes no arguments, the default value `0` is used.

```
fun foo(i: Int = 0): String = "$i!"

fun apply(func: () -> String): String = func()

fun main() {
    println(apply(::foo))
}
```

Previously, you had to write an additional overload for either the `apply` or `foo` function.

```
// some new overload
fun applyInt(func: (Int) -> String): String = func(0)
```

Function references in Unit-returning functions

In Kotlin 1.4, you can use callable references to functions returning any type in `Unit`-returning functions. Before Kotlin 1.4, you could only use lambda arguments in this case. Now you can use both lambda arguments and callable references.

```
fun foo(f: () -> Unit) { }
fun returnsInt(): Int = 42

fun main() {
    foo { returnsInt() } // this was the only way to do it  before 1.4
    foo(::returnsInt) // starting from 1.4, this also works
}
```

References that adapt based on the number of arguments in a function

Now you can adapt callable references to functions when passing a variable number of arguments (`vararg`) . You can pass any number of parameters of the same type at the end of the list of passed arguments.

```
fun foo(x: Int, vararg y: String) {}

fun use0(f: (Int) -> Unit) {}
fun use1(f: (Int, String) -> Unit) {}
fun use2(f: (Int, String, String) -> Unit) {}

fun test() {
    use0(::foo)
    use1(::foo)
    use2(::foo)
}
```

Suspend conversion on callable references

In addition to suspend conversion on lambdas, Kotlin now supports suspend conversion on callable references starting from version 1.4.0.

```
fun call() {}
fun takeSuspend(f: suspend () -> Unit) {}

fun test() {
    takeSuspend { call() } // OK before 1.4
    takeSuspend(::call) // In Kotlin 1.4, it also works
}
```

Using break and continue inside when expressions included in loops

In Kotlin 1.3, you could not use unqualified `break` and `continue` inside `when` expressions included in loops. The reason was that these keywords were reserved for possible fall-through behavior in `when` expressions.

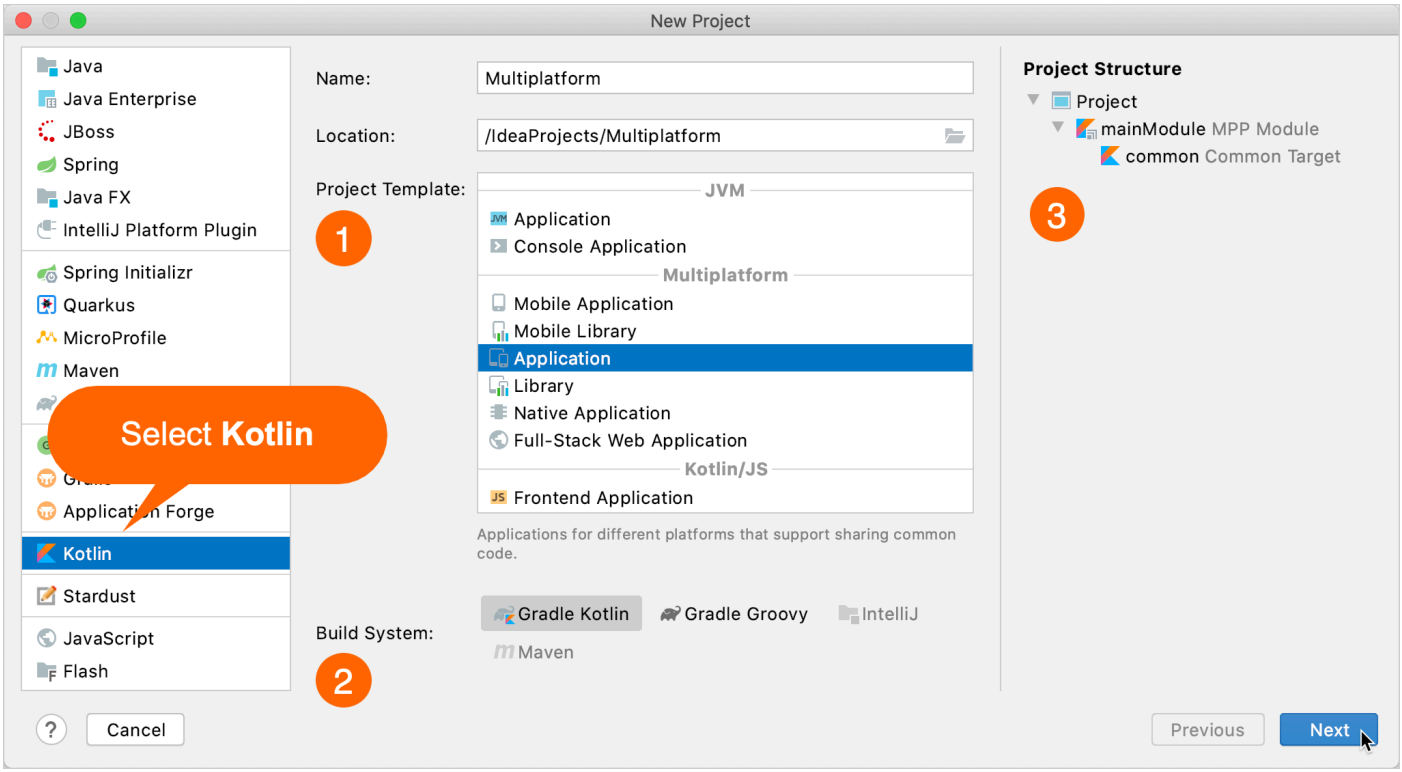
That's why if you wanted to use `break` and `continue` inside `when` expressions in loops, you had to label them, which became rather cumbersome.

```
fun test(xs: List<Int>) {
    LOOP@for (x in xs) {
        when (x) {
            2 -> continue@LOOP
            17 -> break@LOOP
            else -> println(x)
        }
    }
}
```

In Kotlin 1.4, you can use `break` and `continue` without labels inside `when` expressions included in loops. They behave as expected by terminating the nearest enclosing loop or proceeding to its next step.

```
fun test(xs: List<Int>) {
    for (x in xs) {
        when (x) {
            2 -> continue
            17 -> break
            else -> println(x)
        }
    }
}
```

The fall-through behavior inside `when` is subject to further design.



New tools in the IDE

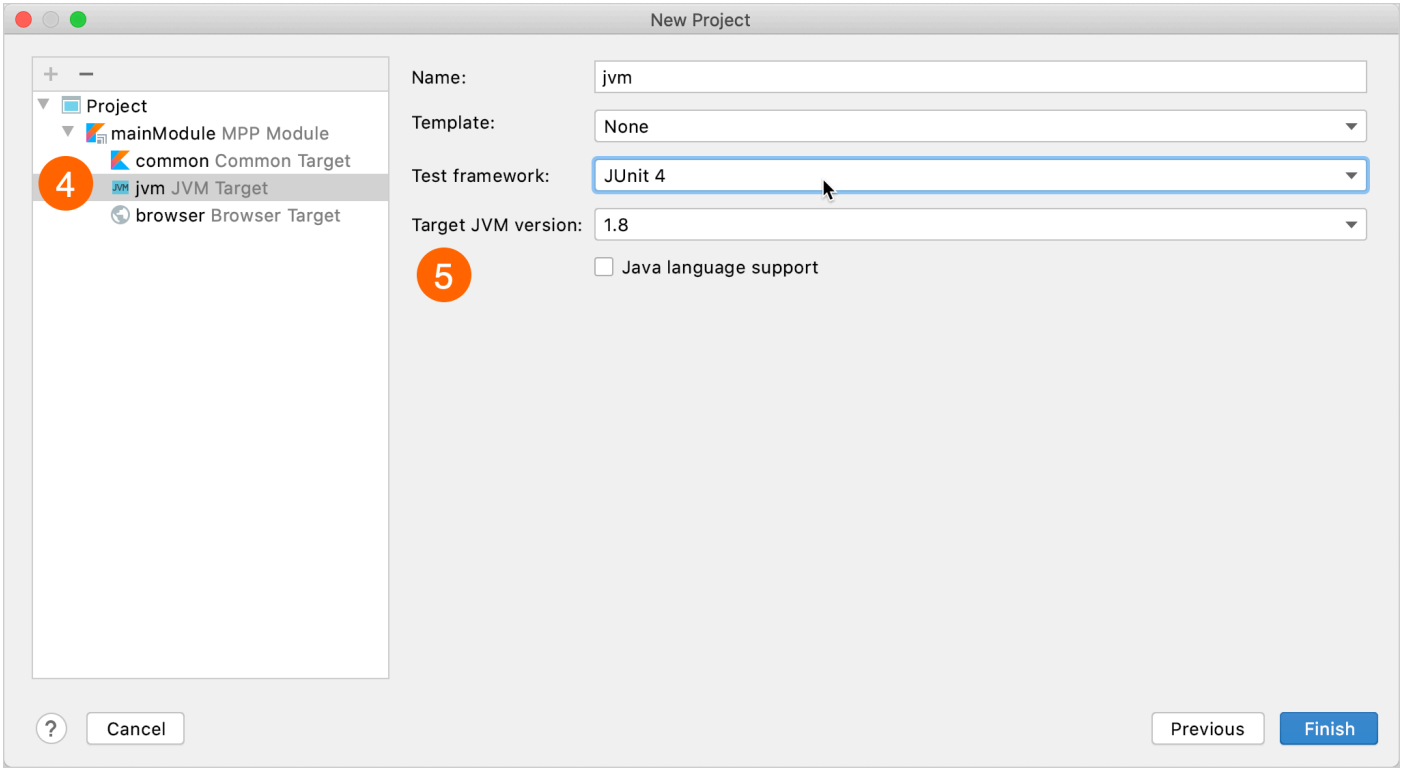
With Kotlin 1.4, you can use the new tools in IntelliJ IDEA to simplify Kotlin development:

- New flexible Project Wizard
- Coroutine Debugger

New flexible Project Wizard

With the flexible new Kotlin Project Wizard, you have a place to easily create and configure different types of Kotlin projects, including multiplatform projects, which can be difficult to configure without a UI.

Kotlin Project Wizard – Multiplatform project



The new Kotlin Project Wizard is both simple and flexible:

1. *Select the project template*, depending on what you're trying to do. More templates will be added in the future.

2. *Select the build system* – Gradle (Kotlin or Groovy DSL), Maven, or IntelliJ IDEA.
   The Kotlin Project Wizard will only show the build systems supported on the selected project template.
3. *Preview the project structure* directly on the main screen.

Then you can finish creating your project or, optionally, *configure the project* on the next screen:

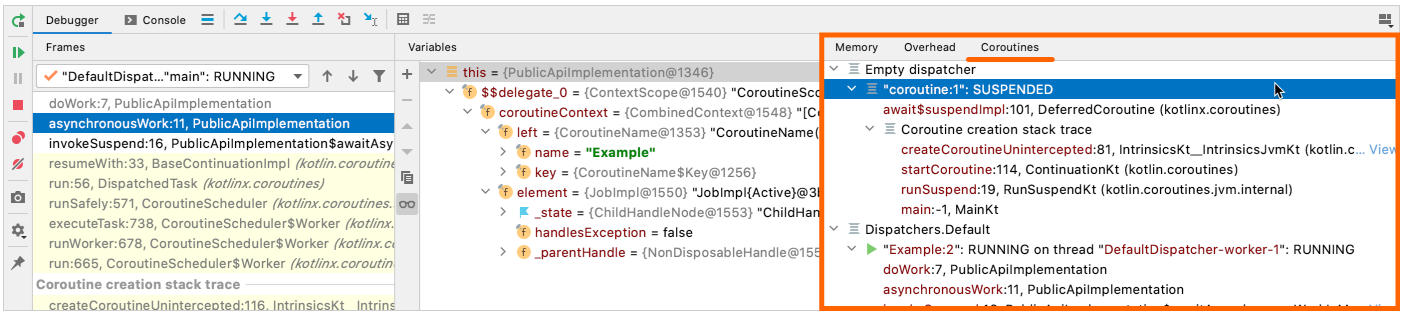
4. *Add/remove modules and targets* supported for this project template.
5. *Configure module and target settings*, for example, the target JVM version, target template, and test framework.

Kotlin Project Wizard - Configure targets

In the future, we are going to make the Kotlin Project Wizard even more flexible by adding more configuration options and templates.

You can try out the new Kotlin Project Wizard by working through these tutorials:

- Create a console application based on Kotlin/JVM
- Create a Kotlin/JS application for React
- Create a Kotlin/Native application



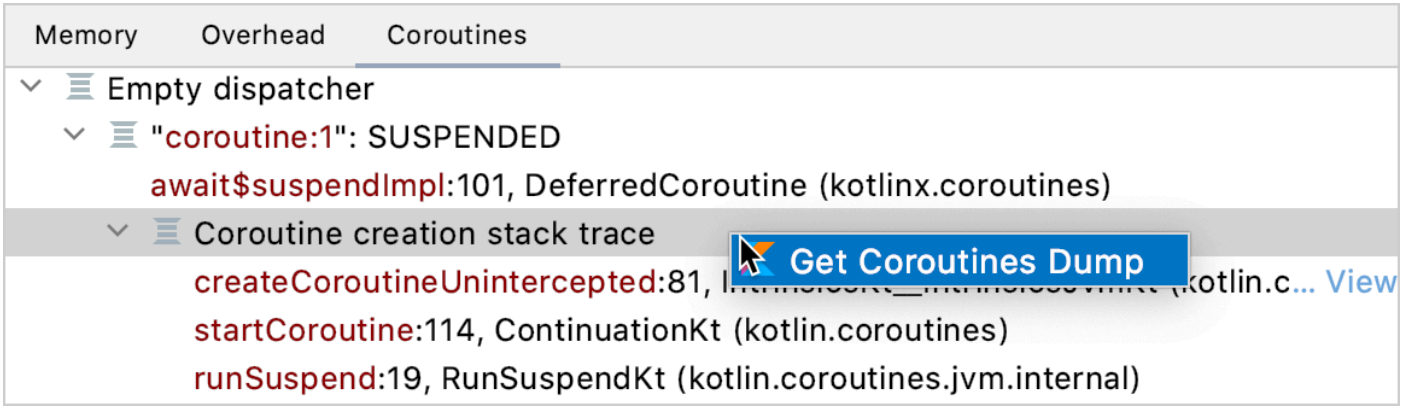
Coroutine Debugger

Many people already use coroutines for asynchronous programming. But when it came to debugging, working with coroutines before Kotlin 1.4, could be a real pain. Since coroutines jumped between threads, it was difficult to understand what a specific coroutine was doing and check its context. In some cases, tracking steps over breakpoints simply didn't work. As a result, you had to rely on logging or mental effort to debug code that used coroutines.

In Kotlin 1.4, debugging coroutines is now much more convenient with the new functionality shipped with the Kotlin plugin.

Debugging works for versions 1.3.8 or later of `kotlinx-coroutines-core`.

The **Debug Tool Window** now contains a new **Coroutines** tab. In this tab, you can find information about both currently running and suspended coroutines. The coroutines are grouped by the dispatcher they are running on.



Debugging coroutines

Now you can:

- Easily check the state of each coroutine.
- See the values of local and captured variables for both running and suspended coroutines.
- See a full coroutine creation stack, as well as a call stack inside the coroutine. The stack includes all frames with variable values, even those that would be lost during standard debugging.

If you need a full report containing the state of each coroutine and its stack, right-click inside the **Coroutines** tab, and then click **Get Coroutines Dump**. Currently, the coroutines dump is rather simple, but we're going to make it more readable and helpful in future versions of Kotlin.

Coroutines Dump

Learn more about debugging coroutines in this blog post and IntelliJ IDEA documentation.

New compiler

The new Kotlin compiler is going to be really fast; it will unify all the supported platforms and provide an API for compiler extensions. It's a long-term project, and we've already completed several steps in Kotlin 1.4.0:

- New, more powerful type inference algorithm is enabled by default.
- New JVM and JS IR backends. They will become the default once we stabilize them.

New more powerful type inference algorithm

Kotlin 1.4 uses a new, more powerful type inference algorithm. This new algorithm was already available to try in Kotlin 1.3 by specifying a compiler option, and now it's used by default. You can find the full list of issues fixed in the new algorithm in YouTrack. Here you can find some of the most noticeable improvements:

- More cases where type is inferred automatically
- Smart casts for a lambda's last expression
- Smart casts for callable references
- Better inference for delegated properties
- SAM conversion for Java interfaces with different arguments
- Java SAM interfaces in Kotlin

More cases where type is inferred automatically

The new inference algorithm infers types for many cases where the old algorithm required you to specify them explicitly. For instance, in the following example the type of the lambda parameter `it` is correctly inferred to `String?`:

```
val rulesMap: Map<String, (String?) -> Boolean> = mapOf(
    "weak" to { it != null },
    "medium" to { !it.isNullOrBlank() },
    "strong" to { it != null && "^[a-zA-Z0-9]+$".toRegex().matches(it) }
)

fun main() {
    println(rulesMap.getValue("weak")("abc!"))
    println(rulesMap.getValue("strong")("abc"))
    println(rulesMap.getValue("strong")("abc!"))
}
```

In Kotlin 1.3, you needed to introduce an explicit lambda parameter or replace `to` with a `Pair` constructor with explicit generic arguments to make it work.

Smart casts for a lambda's last expression

In Kotlin 1.3, the last expression inside a lambda wasn't smart cast unless you specified the expected type. Thus, in the following example, Kotlin 1.3 infers `String?` as the type of the `result` variable:

```
val result = run {
    var str = currentValue()
    if (str == null) {
        str = "test"
    }
    str // the Kotlin compiler knows that str is not null here
}
// The type of 'result' is String? in Kotlin 1.3 and String in Kotlin 1.4
```

In Kotlin 1.4, thanks to the new inference algorithm, the last expression inside a lambda gets smart cast, and this new, more precise type is used to infer the resulting lambda type. Thus, the type of the `result` variable becomes `String`.

In Kotlin 1.3, you often needed to add explicit casts (either `!!` or type casts like `as String`) to make such cases work, and now these casts have become unnecessary.

Smart casts for callable references

In Kotlin 1.3, you couldn't access a member reference of a smart cast type. Now in Kotlin 1.4 you can:

```
import kotlin.reflect.KFunction

sealed class Animal
class Cat : Animal() {
    fun meow() {
        println("meow")
    }
}

class Dog : Animal() {
    fun woof() {
        println("woof")
    }
}

fun perform(animal: Animal) {
    val kFunction: KFunction<*> = when (animal) {
        is Cat -> animal::meow
        is Dog -> animal::woof
    }
    kFunction.call()
}

fun main() {
    perform(Cat())
}
```

You can use different member references `animal::meow` and `animal::woof` after the animal variable has been smart cast to specific types `Cat` and `Dog`. After type checks, you can access member references corresponding to subtypes.

Better inference for delegated properties

The type of a delegated property wasn't taken into account while analyzing the delegate expression which follows the `by` keyword. For instance, the following code didn't compile before, but now the compiler correctly infers the types of the `old` and `new` parameters as `String?`:

```
import kotlin.properties.Delegates

fun main() {
    var prop: String? by Delegates.observable(null) { p, old, new ->
        println("$old -> $new")
    }
    prop = "abc"
    prop = "xyz"
}
```

SAM conversion for Java interfaces with different arguments

Kotlin has supported SAM conversions for Java interfaces from the beginning, but there was one case that wasn't supported, which was sometimes annoying when working with existing Java libraries. If you called a Java method that took two SAM interfaces as parameters, both arguments needed to be either lambdas or regular objects. You couldn't pass one argument as a lambda and another as an object.

The new algorithm fixes this issue, and you can pass a lambda instead of a SAM interface in any case, which is the way you'd naturally expect it to work.

```
// FILE: A.java
public class A {
    public static void foo(Runnable r1, Runnable r2) {}
}
```

```
// FILE: test.kt
fun test(r1: Runnable) {
    A.foo(r1) {}  // Works in Kotlin 1.4
}
```

Java SAM interfaces in Kotlin

In Kotlin 1.4, you can use Java SAM interfaces in Kotlin and apply SAM conversions to them.

```
import java.lang.Runnable

fun foo(r: Runnable) {}

fun test() {
    foo { } // OK
}
```

In Kotlin 1.3, you would have had to declare the function `foo` above in Java code to perform a SAM conversion.

Unified backends and extensibility

In Kotlin, we have three backends that generate executables: Kotlin/JVM, Kotlin/JS, and Kotlin/Native. Kotlin/JVM and Kotlin/JS don't share much code since they were developed independently of each other. Kotlin/Native is based on a new infrastructure built around an intermediate representation (IR) for Kotlin code.

We are now migrating Kotlin/JVM and Kotlin/JS to the same IR. As a result, all three backends share a lot of logic and have a unified pipeline. This allows us to implement most features, optimizations, and bug fixes only once for all platforms. Both new IR-based back-ends are in Alpha.

A common backend infrastructure also opens the door for multiplatform compiler extensions. You will be able to plug into the pipeline and add custom processing and transformations that will automatically work for all platforms.

We encourage you to use our new JVM IR and JS IR backends, which are currently in Alpha, and share your feedback with us.

Kotlin/JVM

Kotlin 1.4.0 includes a number of JVM-specific improvements, such as:

- New JVM IR backend
- New modes for generating default methods in interfaces
- Unified exception type for null checks
- Type annotations in the JVM bytecode

New JVM IR backend

Along with Kotlin/JS, we are migrating Kotlin/JVM to the unified IR backend, which allows us to implement most features and bug fixes once for all platforms. You will also be able to benefit from this by creating multiplatform extensions that will work for all platforms.

Kotlin 1.4.0 does not provide a public API for such extensions yet, but we are working closely with our partners, including Jetpack Compose, who are already building their compiler plugins using our new backend.

We encourage you to try out the new Kotlin/JVM backend, which is currently in Alpha, and to file any issues and feature requests to our issue tracker. This will help us to unify the compiler pipelines and bring compiler extensions like Jetpack Compose to the Kotlin community more quickly.

To enable the new JVM IR backend, specify an additional compiler option in your Gradle build script:

```
kotlinOptions.useIR = true
```

If you enable Jetpack Compose, you will automatically be opted in to the new JVM backend without needing to specify the compiler option in `kotlinOptions`.

When using the command-line compiler, add the compiler option `-Xuse-ir`.

You can use code compiled by the new JVM IR backend only if you've enabled the new backend. Otherwise, you will get an error. Considering this, we don't recommend that library authors switch to the new backend in production.

New modes for generating default methods

When compiling Kotlin code to targets JVM 1.8 and above, you could compile non-abstract methods of Kotlin interfaces into Java's `default` methods. For this purpose, there was a mechanism that includes the `@JvmDefault` annotation for marking such methods and the `-Xjvm-default` compiler option that enables processing of this annotation.

In 1.4.0, we've added a new mode for generating default methods: `-Xjvm-default=all` compiles *all* non-abstract methods of Kotlin interfaces to `default` Java methods. For compatibility with the code that uses the interfaces compiled without `default`, we also added `all-compatibility` mode.

For more information about default methods in the Java interop, see the interoperability documentation and this blog post.

Unified exception type for null checks

Starting from Kotlin 1.4.0, all runtime null checks will throw a `java.lang.NullPointerException` instead of `KotlinNullPointerException`, `IllegalStateException`, `IllegalArgumentException`, and `TypeCastException`. This applies to: the `!!` operator, parameter null checks in the method preamble, platform-typed expression null checks, and the `as` operator with a non-nullable type. This doesn't apply to `lateinit` null checks and explicit library function calls like `checkNotNull` or `requireNotNull`.

This change increases the number of possible null check optimizations that can be performed either by the Kotlin compiler or by various kinds of bytecode processing tools, such as the Android R8 optimizer.

Note that from a developer's perspective, things won't change that much: the Kotlin code will throw exceptions with the same error messages as before. The type of exception changes, but the information passed stays the same.

Type annotations in the JVM bytecode

Kotlin can now generate type annotations in the JVM bytecode (target version 1.8+), so that they become available in Java reflection at runtime. To emit the type annotation in the bytecode, follow these steps:

1. Make sure that your declared annotation has a proper annotation target (Java's `ElementType.TYPE_USE` or Kotlin's `AnnotationTarget.TYPE`) and retention (`AnnotationRetention.RUNTIME`).
2. Compile the annotation class declaration to JVM bytecode target version 1.8+. You can specify it with `-jvm-target=1.8` compiler option.
3. Compile the code that uses the annotation to JVM bytecode target version 1.8+ (`-jvm-target=1.8`) and add the `-Xemit-jvm-type-annotations` compiler option.

Note that the type annotations from the standard library aren't emitted in the bytecode for now because the standard library is compiled with the target version 1.6.

So far, only the basic cases are supported:

- Type annotations on method parameters, method return types and property types;
- Invariant projections of type arguments, such as `Smth<@Ann Foo>`, `Array<@Ann Foo>`.

In the following example, the `@Foo` annotation on the `String` type can be emitted to the bytecode and then used by the library code:

```
@Target(AnnotationTarget.TYPE)
annotation class Foo

class A {
    fun foo(): @Foo String = "OK"
}
```

Kotlin/JS

On the JS platform, Kotlin 1.4.0 provides the following improvements:

- New Gradle DSL
- New JS IR backend

New Gradle DSL

The `kotlin.js` Gradle plugin comes with an adjusted Gradle DSL, which provides a number of new configuration options and is more closely aligned to the DSL used by the `kotlin-multiplatform` plugin. Some of the most impactful changes include:

- Explicit toggles for the creation of executable files via `binaries.executable()`. Read more about the executing Kotlin/JS and its environment here.
- Configuration of webpack's CSS and style loaders from within the Gradle configuration via `cssSupport`. Read more about using CSS and style loaders here.

- Improved management for npm dependencies, with mandatory version numbers or semver version ranges, as well as support for *development*, *peer*, and *optional* npm dependencies using `devNpm`, `optionalNpm` and `peerNpm`. Read more about dependency management for npm packages directly from Gradle here.
- Stronger integrations for Dukat, the generator for Kotlin external declarations. External declarations can now be generated at build time, or can be manually generated via a Gradle task.

New JS IR backend

The IR backend for Kotlin/JS, which currently has Alpha stability, provides some new functionality specific to the Kotlin/JS target which is focused around the generated code size through dead code elimination, and improved interoperation with JavaScript and TypeScript, among others.

To enable the Kotlin/JS IR backend, set the key `kotlin.js.compiler=ir` in your `gradle.properties`, or pass the `IR` compiler type to the `js` function of your Gradle build script:

```
kotlin {
    js(IR) { // or: LEGACY, BOTH
        // ...
    }
    binaries.executable()
}
```

For more detailed information about how to configure the new backend, check out the Kotlin/JS IR compiler documentation.

With the new @JsExport annotation and the ability to generate TypeScript definitions **from Kotlin code**, the Kotlin/JS IR compiler backend improves JavaScript & TypeScript interoperability. This also makes it easier to integrate Kotlin/JS code with existing tooling, to create **hybrid applications** and leverage code-sharing functionality in multiplatform projects.

Learn more about the available features in the Kotlin/JS IR compiler backend.

Kotlin/Native

In 1.4.0, Kotlin/Native got a significant number of new features and improvements, including:

- Support for suspending functions in Swift and Objective-C
- Objective-C generics support by default
- Exception handling in Objective-C/Swift interop
- Generate release .dSYMs on Apple targets by default
- Performance improvements
- Simplified management of CocoaPods dependencies

Support for Kotlin's suspending functions in Swift and Objective-C

In 1.4.0, we add the basic support for suspending functions in Swift and Objective-C. Now, when you compile a Kotlin module into an Apple framework, suspending functions are available in it as functions with callbacks (`completionHandler` in the Swift/Objective-C terminology). When you have such functions in the generated framework's header, you can call them from your Swift or Objective-C code and even override them.

For example, if you write this Kotlin function:

```
suspend fun queryData(id: Int): String = ...
```

...then you can call it from Swift like so:

```
queryData(id: 17) { result, error in
   if let e = error {
       print("ERROR: \(e)")
   } else {
       print(result!)
   }
}
```

Learn more about using suspending functions in Swift and Objective-C.

Objective-C generics support by default

Previous versions of Kotlin provided experimental support for generics in Objective-C interop. Since 1.4.0, Kotlin/Native generates Apple frameworks with generics from Kotlin code by default. In some cases, this may break existing Objective-C or Swift code calling Kotlin frameworks. To have the framework header written without generics, add the `-Xno-objc-generics` compiler option.

```
kotlin {
    targets.withType<org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget> {
        binaries.all {
            freeCompilerArgs += "-Xno-objc-generics"
        }
    }
}
```

Please note that all specifics and limitations listed in the documentation on interoperability with Objective-C are still valid.

Exception handling in Objective-C/Swift interop

In 1.4.0, we slightly change the Swift API generated from Kotlin with respect to the way exceptions are translated. There is a fundamental difference in error handling between Kotlin and Swift. All Kotlin exceptions are unchecked, while Swift has only checked errors. Thus, to make Swift code aware of expected exceptions, Kotlin functions should be marked with a `@Throws` annotation specifying a list of potential exception classes.

When compiling to Swift or the Objective-C framework, functions that have or are inheriting `@Throws` annotation are represented as `NSError*`-producing methods in Objective-C and as `throws` methods in Swift.

Previously, any exceptions other than `RuntimeException` and `Error` were propagated as `NSError`. Now this behavior changes: now `NSError` is thrown only for exceptions that are instances of classes specified as parameters of `@Throws` annotation (or their subclasses). Other Kotlin exceptions that reach Swift/Objective-C are considered unhandled and cause program termination.

Generate release .dSYMs on Apple targets by default

Starting with 1.4.0, the Kotlin/Native compiler produces debug symbol files (`.dSYM`s) for release binaries on Darwin platforms by default. This can be disabled with the `-Xadd-light-debug=disable` compiler option. On other platforms, this option is disabled by default. To toggle this option in Gradle, use:

```
kotlin {
    targets.withType<org.jetbrains.kotlin.gradle.plugin.mpp.KotlinNativeTarget> {
        binaries.all {
            freeCompilerArgs += "-Xadd-light-debug={enable|disable}"
        }
    }
}
```

Learn more about crash report symbolication.

Performance improvements

Kotlin/Native has received a number of performance improvements that speed up both the development process and execution. Here are some examples:

- To improve the speed of object allocation, we now offer the mimalloc memory allocator as an alternative to the system allocator. mimalloc works up to two times faster on some benchmarks. Currently, the usage of mimalloc in Kotlin/Native is experimental; you can switch to it using the `-Xallocator=mimalloc` compiler option.
- We've reworked how C interop libraries are built. With the new tooling, Kotlin/Native produces interop libraries up to 4 times as fast as before, and artifacts are 25% to 30% the size they used to be.
- Overall runtime performance has improved because of optimizations in GC. This improvement will be especially apparent in projects with a large number of long-lived objects. `HashMap` and `HashSet` collections now work faster by escaping redundant boxing.
- In 1.3.70 we introduced two new features for improving the performance of Kotlin/Native compilation: caching project dependencies and running the compiler from the Gradle daemon. Since that time, we've managed to fix numerous issues and improve the overall stability of these features.

Simplified management of CocoaPods dependencies

Previously, once you integrated your project with the dependency manager CocoaPods, you could build an iOS, macOS, watchOS, or tvOS part of your project only in Xcode, separate from other parts of your multiplatform project. These other parts could be built in IntelliJ IDEA.

Moreover, every time you added a dependency on an Objective-C library stored in CocoaPods (Pod library), you had to switch from IntelliJ IDEA to Xcode, call `pod install`, and run the Xcode build there.

Now you can manage Pod dependencies right in IntelliJ IDEA while enjoying the benefits it provides for working with code, such as code highlighting and completion. You can also build the whole Kotlin project with Gradle, without having to switch to Xcode. This means you only have to go to Xcode when you need to write Swift/Objective-C code or run your application on a simulator or device.

Now you can also work with Pod libraries stored locally.

Depending on your needs, you can add dependencies between:

- A Kotlin project and Pod libraries stored remotely in the CocoaPods repository or stored locally on your machine.
- A Kotlin Pod (Kotlin project used as a CocoaPods dependency) and an Xcode project with one or more targets.

Complete the initial configuration, and when you add a new dependency to `cocoapods`, just re-import the project in IntelliJ IDEA. The new dependency will be added automatically. No additional steps are required.

Learn how to add dependencies.

Kotlin Multiplatform

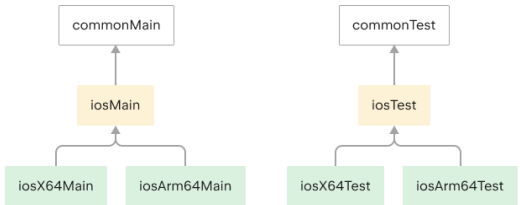
Support for multiplatform projects is in Alpha. It may change incompatibly and require manual migration in the future. We appreciate your feedback on it in YouTrack.

Kotlin Multiplatform reduces time spent writing and maintaining the same code for different platforms while retaining the flexibility and benefits of native programming. We continue investing our effort in multiplatform features and improvements:

- Sharing code in several targets with the hierarchical project structure
- Leveraging native libs in the hierarchical structure
- Specifying kotlinx dependencies only once

Multiplatform projects require Gradle 6.0 or later.

Sharing code in several targets with the hierarchical project structure



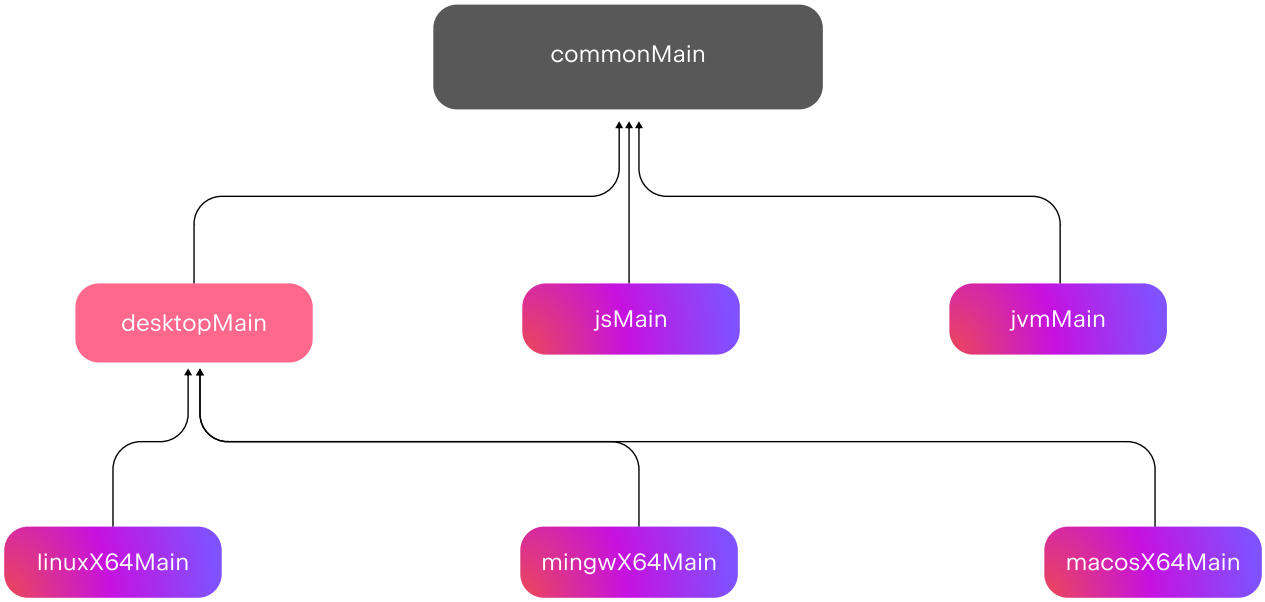
With the new hierarchical project structure support, you can share code among several platforms in a multiplatform project.

Previously, any code added to a multiplatform project could be placed either in a platform-specific source set, which is limited to one target and can't be reused by any other platform, or in a common source set, like `commonMain` or `commonTest`, which is shared across all the platforms in the project. In the common source set, you could only call a platform-specific API by using an `expect` declaration that needs platform-specific `actual` implementations.

This made it easy to share code on all platforms, but it was not so easy to share between only some of the targets, especially similar ones that could potentially reuse a lot of the common logic and third-party APIs.

For example, in a typical multiplatform project targeting iOS, there are two iOS-related targets: one for iOS ARM64 devices, and the other for the x64 simulator. They have separate platform-specific source sets, but in practice, there is rarely a need for different code for the device and simulator, and their dependencies are much alike. So iOS-specific code could be shared between them.

Apparently, in this setup, it would be desirable to have a *shared source set for two iOS targets*, with Kotlin/Native code that could still directly call any of the APIs that are common to both the iOS device and the simulator.



Code shared for iOS targets

Now you can do this with the hierarchical project structure support, which infers and adapts the API and language features available in each source set based on which targets consume them.

For common combinations of targets, you can create a hierarchical structure with target shortcuts. For example, create two iOS targets and the shared source set shown above with the `ios()` shortcut:

```
kotlin {
    ios() // iOS device and simulator targets; iosMain and iosTest source sets
}
```

For other combinations of targets, create a hierarchy manually by connecting the source sets with the `dependsOn` relation.

Hierarchical structure

Kotlin

```
kotlin{
    sourceSets {
        val desktopMain by creating {
            dependsOn(commonMain)
        }
        val linuxX64Main by getting {
            dependsOn(desktopMain)
        }
        val mingwX64Main by getting {
            dependsOn(desktopMain)
        }
        val macosX64Main by getting {
            dependsOn(desktopMain)
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        desktopMain {
            dependsOn(commonMain)
        }
        linuxX64Main {
            dependsOn(desktopMain)
        }
        mingwX64Main {
            dependsOn(desktopMain)
        }
        macosX64Main {
            dependsOn(desktopMain)
        }
    }
}
```

Thanks to the hierarchical project structure, libraries can also provide common APIs for a subset of targets. Learn more about sharing code in libraries.

Leveraging native libs in the hierarchical structure

You can use platform-dependent libraries, such as Foundation, UIKit, and POSIX, in source sets shared among several native targets. This can help you share more native code without being limited by platform-specific dependencies.

No additional steps are required – everything is done automatically. IntelliJ IDEA will help you detect common declarations that you can use in the shared code.

Learn more about usage of platform-dependent libraries.

Specifying dependencies only once

From now on, instead of specifying dependencies on different variants of the same library in shared and platform-specific source sets where it is used, you should specify a dependency only once in the shared source set.

Kotlin

```
kotlin {
    sourceSets {
        val commonMain by getting {
            dependencies {
                implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
            }
        }
    }
}
```

Groovy

```
kotlin {
    sourceSets {
        commonMain {
            dependencies {
                implementation 'org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0'
            }
        }
    }
}
```

Don't use kotlinx library artifact names with suffixes specifying the platform, such as `-common`, `-native`, or similar, as they are NOT supported anymore. Instead, use the library base artifact name, which in the example above is `kotlinx-coroutines-core`.

However, the change doesn't currently affect:

- The `stdlib` library – starting from Kotlin 1.4.0, the stdlib dependency is added automatically.
- The `kotlin.test` library – you should still use `test-common` and `test-annotations-common`. These dependencies will be addressed later.

If you need a dependency only for a specific platform, you can still use platform-specific variants of standard and kotlinx libraries with such suffixes as `-jvm` or `-js`, for example `kotlinx-coroutines-core-jvm`.

Learn more about configuring dependencies.

Gradle project improvements

Besides Gradle project features and improvements that are specific to Kotlin Multiplatform, Kotlin/JVM, Kotlin/Native, and Kotlin/JS, there are several changes applicable to all Kotlin Gradle projects:

- Dependency on the standard library is now added by default
- Kotlin projects require a recent version of Gradle
- Improved support for Kotlin Gradle DSL in the IDE

Dependency on the standard library added by default

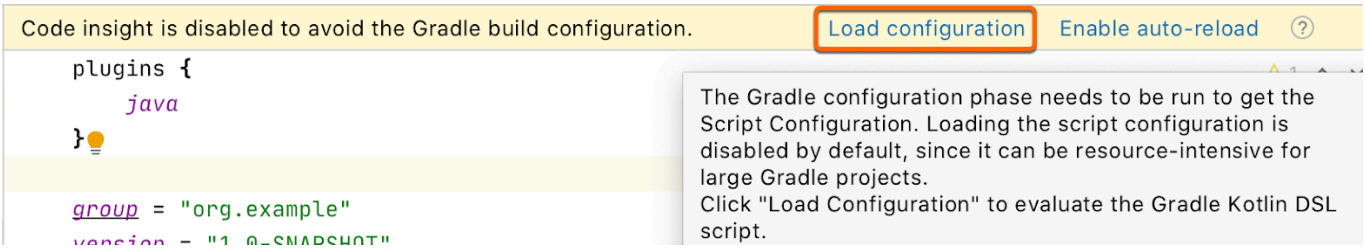
You no longer need to declare a dependency on the `stdlib` library in any Kotlin Gradle project, including a multiplatform one. The dependency is added by default.

The automatically added standard library will be the same version of the Kotlin Gradle plugin, since they have the same versioning.

For platform-specific source sets, the corresponding platform-specific variant of the library is used, while a common standard library is added to the rest. The Kotlin Gradle plugin will select the appropriate JVM standard library depending on the `kotlinOptions.jvmTarget` compiler option of your Gradle build script.

Learn how to change the default behavior.

Minimum Gradle version for Kotlin projects



To enjoy the new features in your Kotlin projects, update Gradle to the latest version. Multiplatform projects require Gradle 6.0 or later, while other Kotlin projects work with Gradle 5.4 or later.

Improved *.gradle.kts support in the IDE

In 1.4.0, we continued improving the IDE support for Gradle Kotlin DSL scripts (`*.gradle.kts` files). Here is what the new version brings:

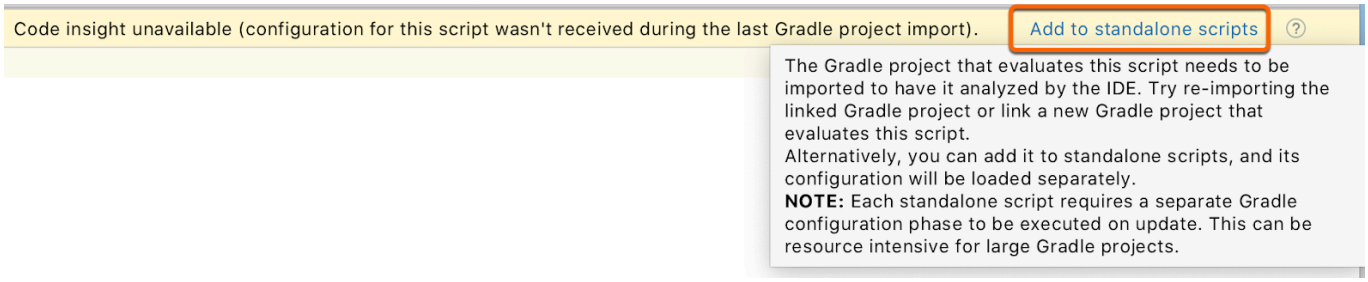
- *Explicit loading of script configurations* for better performance. Previously, the changes you make to the build script were loaded automatically in the background. To improve the performance, we've disabled the automatic loading of build script configuration in 1.4.0. Now the IDE loads the changes only when you explicitly apply them.

  In Gradle versions earlier than 6.0, you need to manually load the script configuration by clicking **Load Configuration** in the editor.

*.gradle.kts – Load Configuration

  In Gradle 6.0 and above, you can explicitly apply changes by clicking **Load Gradle Changes** or by reimporting the Gradle project.

  We've added one more action in IntelliJ IDEA 2020.1 with Gradle 6.0 and above – **Load Script Configurations**, which loads changes to the script configurations without updating the whole project. This takes much less time than reimporting the whole project.



*.gradle.kts – Load Script Changes and Load Gradle Changes

  You should also **Load Script Configurations** for newly created scripts or when you open a project with new Kotlin plugin for the first time.

  With Gradle 6.0 and above, you are now able to load all scripts at once as opposed to the previous implementation where they were loaded individually. Since each request requires the Gradle configuration phase to be executed, this could be resource-intensive for large Gradle projects.

  Currently, such loading is limited to `build.gradle.kts` and `settings.gradle.kts` files (please vote for the related issue). To enable highlighting for `init.gradle.kts` or applied script plugins, use the old mechanism –

adding them to standalone scripts. Configuration for that scripts will be loaded separately when you need it. You can also enable auto-reload for such scripts.

*.gradle.kts – Add to standalone scripts

- *Better error reporting*. Previously you could only see errors from the Gradle Daemon in separate log files. Now the Gradle Daemon returns all the information about errors directly and shows it in the Build tool window. This saves you both time and effort.

Standard library

Here is the list of the most significant changes to the Kotlin standard library in 1.4.0:

- Common exception processing API
- New functions for arrays and collections
- Functions for string manipulations
- Bit operations
- Delegated properties improvements
- Converting from KType to Java Type
- Proguard configurations for Kotlin reflection
- Improving the existing API
- module-info descriptors for stdlib artifacts
- Deprecations
- Exclusion of the deprecated experimental coroutines

Common exception processing API

The following API elements have been moved to the common library:

- `Throwable.stackTraceToString()` extension function, which returns the detailed description of this throwable with its stack trace, and `Throwable.printStackTrace()`, which prints this description to the standard error output.
- `Throwable.addSuppressed()` function, which lets you specify the exceptions that were suppressed in order to deliver the exception, and the `Throwable.suppressedExceptions` property, which returns a list of all the suppressed exceptions.
- `@Throws` annotation, which lists exception types that will be checked when the function is compiled to a platform method (on JVM or native platforms).

New functions for arrays and collections

Collections

In 1.4.0, the standard library includes a number of useful functions for working with **collections**:

- `setOfNotNull()`, which makes a set consisting of all the non-null items among the provided arguments.

```
fun main() {
    val set = setOfNotNull(null, 1, 2, 0, null)
    println(set)
}
```

- `shuffled()` for sequences.

```
fun main() {
    val numbers = (0 until 50).asSequence()
    val result = numbers.map { it * 2 }.shuffled().take(5)
    println(result.toList()) //five random even numbers below 100
}
```

- `*Indexed()` counterparts for `onEach()` and `flatMap()`. The operation that they apply to the collection elements has the element index as a parameter.

```
fun main() {
    listOf("a", "b", "c", "d").onEachIndexed {
        index, item -> println(index.toString() + ":" + item)
    }

   val list = listOf("hello", "kot", "lin", "world")
          val kotlin = list.flatMapIndexed { index, item ->
              if (index in 1..2) item.toList() else emptyList()
          }
          println(kotlin)
}
```

- `*OrNull()` counterparts `randomOrNull()`, `reduceOrNull()`, and `reduceIndexedOrNull()`. They return `null` on empty collections.

```
fun main() {
     val empty = emptyList<Int>()
     empty.reduceOrNull { a, b -> a + b }
     //empty.reduce { a, b -> a + b } // Exception: Empty collection can't be reduced.
}
```

- `runningFold()`, its synonym `scan()`, and `runningReduce()` apply the given operation to the collection elements sequentially, similarly to `fold()` and `reduce()`; the difference is that these new functions return the whole sequence of intermediate results.

```
fun main() {
    val numbers = mutableListOf(0, 1, 2, 3, 4, 5)
    val runningReduceSum = numbers.runningReduce { sum, item -> sum + item }
    val runningFoldSum = numbers.runningFold(10) { sum, item -> sum + item }
    println(runningReduceSum.toString())
    println(runningFoldSum.toString())
}
```

- `sumOf()` takes a selector function and returns a sum of its values for all elements of a collection. `sumOf()` can produce sums of the types `Int`, `Long`, `Double`, `UInt`, and `ULong`. On the JVM, `BigInteger` and `BigDecimal` are also available.

```
data class OrderItem(val name: String, val price: Double, val count: Int)

fun main() {
    val order = listOf<OrderItem>(
        OrderItem("Cake", price = 10.0, count = 1),
        OrderItem("Coffee", price = 2.5, count = 3),
        OrderItem("Tea", price = 1.5, count = 2))

    val total = order.sumOf { it.price * it.count } // Double
    val count = order.sumOf { it.count } // Int
    println("You've ordered $count items that cost $total in total")
}
```

- The `min()` and `max()` functions have been renamed to `minOrNull()` and `maxOrNull()` to comply with the naming convention used across the Kotlin collections API. An `*OrNull` suffix in the function name means that it returns `null` if the receiver collection is empty. The same applies to `minBy()`, `maxBy()`, `minWith()`, `maxWith()` – in 1.4, they have `*OrNull()` synonyms.

- The new `minOf()` and `maxOf()` extension functions return the minimum and the maximum value of the given selector function on the collection items.

```
data class OrderItem(val name: String, val price: Double, val count: Int)

fun main() {
    val order = listOf<OrderItem>(
        OrderItem("Cake", price = 10.0, count = 1),
        OrderItem("Coffee", price = 2.5, count = 3),
        OrderItem("Tea", price = 1.5, count = 2))
    val highestPrice = order.maxOf { it.price }
    println("The most expensive item in the order costs $highestPrice")
}
```

  There are also `minOfWith()` and `maxOfWith()`, which take a `Comparator` as an argument, and `*OrNull()` versions of all four functions that return `null` on empty collections.

- New overloads for `flatMap` and `flatMapTo` let you use transformations with return types that don't match the receiver type, namely:
  - Transformations to `Sequence` on `Iterable`, `Array`, and `Map`
  - Transformations to `Iterable` on `Sequence`

```
fun main() {
    val list = listOf("kot", "lin")
    val lettersList = list.flatMap { it.asSequence() }
    val lettersSeq = list.asSequence().flatMap { it.toList() }
    println(lettersList)
    println(lettersSeq.toList())
}
```

- `removeFirst()` and `removeLast()` shortcuts for removing elements from mutable lists, and `*orNull()` counterparts of these functions.

Arrays

To provide a consistent experience when working with different container types, we've also added new functions for **arrays**:

- `shuffle()` puts the array elements in a random order.
- `onEach()` performs the given action on each array element and returns the array itself.
- `associateWith()` and `associateWithTo()` build maps with the array elements as keys.
- `reverse()` for array subranges reverses the order of the elements in the subrange.
- `sortDescending()` for array subranges sorts the elements in the subrange in descending order.
- `sort()` and `sortWith()` for array subranges are now available in the common library.

```
fun main() {
    var language = ""
    val letters = arrayOf("k", "o", "t", "l", "i", "n")
    val fileExt = letters.onEach { language += it }
       .filterNot { it in "aeuio" }.take(2)
       .joinToString(prefix = ".", separator = "")
    println(language) // "kotlin"
    println(fileExt) // ".kt"

    letters.shuffle()
    letters.reverse(0, 3)
    letters.sortDescending(2, 5)
    println(letters.contentToString()) // [k, o, t, l, i, n]
}
```

Additionally, there are new functions for conversions between `CharArray` / `ByteArray` and `String`:

- `ByteArray.decodeToString()` and `String.encodeToByteArray()`
- `CharArray.concatToString()` and `String.toCharArray()`

```
fun main() {
        val str = "kotlin"
    val array = str.toCharArray()
    println(array.concatToString())
}
```

ArrayDeque

We've also added the `ArrayDeque` class – an implementation of a double-ended queue. A double-ended queue lets you add or remove elements both at the beginning or end of the queue in an amortized constant time. You can use a double-ended queue by default when you need a queue or a stack in your code.

```
fun main() {
    val deque = ArrayDeque(listOf(1, 2, 3))

    deque.addFirst(0)
    deque.addLast(4)
    println(deque) // [0, 1, 2, 3, 4]

    println(deque.first()) // 0
    println(deque.last()) // 4

    deque.removeFirst()
    deque.removeLast()
    println(deque) // [1, 2, 3]
}
```

The `ArrayDeque` implementation uses a resizable array underneath: it stores the contents in a circular buffer, an `Array`, and resizes this `Array` only when it becomes full.

Functions for string manipulations

The standard library in 1.4.0 includes a number of improvements in the API for string manipulation:

- `StringBuilder` has useful new extension functions: `set()`, `setRange()`, `deleteAt()`, `deleteRange()`, `appendRange()`, and others.

  ```
  fun main() {
              val sb = StringBuilder("Bye Kotlin 1.3.72")
          sb.deleteRange(0, 3)
          sb.insertRange(0, "Hello", 0 ,5)
          sb.set(15, '4')
          sb.setRange(17, 19, "0")
          print(sb.toString())
      //sampleEnd
      }
  ```

- Some existing functions of `StringBuilder` are available in the common library. Among them are `append()`, `insert()`, `substring()`, `setLength()`, and more.
- New functions `Appendable.appendLine()` and `StringBuilder.appendLine()` have been added to the common library. They replace the JVM-only `appendln()` functions of these classes.

  ```
  fun main() {
      println(buildString {
          appendLine("Hello,")
          appendLine("world")
      })
  }
  ```

Bit operations

New functions for bit manipulations:

- `countOneBits()`
- `countLeadingZeroBits()`
- `countTrailingZeroBits()`

- `takeHighestOneBit()`
- `takeLowestOneBit()`
- `rotateLeft()` and `rotateRight()` (experimental)

```
fun main() {
    val number = "1010000".toInt(radix = 2)
    println(number.countOneBits())
    println(number.countTrailingZeroBits())
    println(number.takeHighestOneBit().toString(2))
}
```

Delegated properties improvements

In 1.4.0, we have added new features to improve your experience with delegated properties in Kotlin:

- Now a property can be delegated to another property.
- A new interface `PropertyDelegateProvider` helps create delegate providers in a single declaration.
- `ReadWriteProperty` now extends `ReadOnlyProperty` so you can use both of them for read-only properties.

Aside from the new API, we've made some optimizations that reduce the resulting bytecode size. These optimizations are described in this blog post.

Learn more about delegated properties.

Converting from KType to Java Type

A new extension property `KType.javaType` (currently experimental) in the stdlib helps you obtain a `java.lang.reflect.Type` from a Kotlin type without using the whole `kotlin-reflect` dependency.

```
import kotlin.reflect.javaType
import kotlin.reflect.typeOf

@OptIn(ExperimentalStdlibApi::class)
inline fun <reified T> accessReifiedTypeArg() {
   val kType = typeOf<T>()
   println("Kotlin type: $kType")
   println("Java type: ${kType.javaType}")
}

@OptIn(ExperimentalStdlibApi::class)
fun main() {
   accessReifiedTypeArg<String>()
   // Kotlin type: kotlin.String
   // Java type: class java.lang.String

   accessReifiedTypeArg<List<String>>()
   // Kotlin type: kotlin.collections.List<kotlin.String>
   // Java type: java.util.List<java.lang.String>
}
```

Proguard configurations for Kotlin reflection

Starting from 1.4.0, we have embedded Proguard/R8 configurations for Kotlin Reflection in `kotlin-reflect.jar`. With this in place, most Android projects using R8 or Proguard should work with kotlin-reflect without needing

any additional configuration. You no longer need to copy-paste the Proguard rules for kotlin-reflect internals. But note that you still need to explicitly list all the APIs you're going to reflect on.

Improving the existing API

- Several functions now work on null receivers, for example:
  - `toBoolean()` on strings
  - `contentEquals()`, `contentHashcode()`, `contentToString()` on arrays
- `NaN`, `NEGATIVE_INFINITY`, and `POSITIVE_INFINITY` in `Double` and `Float` are now defined as `const`, so you can use them as annotation arguments.
- New constants `SIZE_BITS` and `SIZE_BYTES` in `Double` and `Float` contain the number of bits and bytes used to represent an instance of the type in binary form.
- The `maxOf()` and `minOf()` top-level functions can accept a variable number of arguments (`vararg`).

module-info descriptors for stdlib artifacts

Kotlin 1.4.0 adds `module-info.java` module information to default standard library artifacts. This lets you use them with jlink tool, which generates custom Java runtime images containing only the platform modules that are required for your app. You could already use jlink with Kotlin standard library artifacts, but you had to use separate artifacts to do so – the ones with the "modular" classifier – and the whole setup wasn't straightforward.
In Android, make sure you use the Android Gradle plugin version 3.2 or higher, which can correctly process jar files with module-info.

Deprecations

toShort() and toByte() of Double and Float

We've deprecated the functions `toShort()` and `toByte()` on `Double` and `Float` because they could lead to unexpected results because of the narrow value range and smaller variable size.

To convert floating-point numbers to `Byte` or `Short`, use the two-step conversion: first, convert them to `Int`, and then convert them again to the target type.

contains(), indexOf(), and lastIndexOf() on floating-point arrays

We've deprecated the `contains()`, `indexOf()`, and `lastIndexOf()` extension functions of `FloatArray` and `DoubleArray` because they use the IEEE 754 standard equality, which contradicts the total order equality in some corner cases. See this issue for details.

min() and max() collection functions

We've deprecated the `min()` and `max()` collection functions in favor of `minOrNull()` and `maxOrNull()`, which more properly reflect their behavior – returning `null` on empty collections. See this issue for details.

Exclusion of the deprecated experimental coroutines

The `kotlin.coroutines.experimental` API was deprecated in favor of kotlin.coroutines in 1.3.0. In 1.4.0, we're completing the deprecation cycle for `kotlin.coroutines.experimental` by removing it from the standard

library. For those who still use it on the JVM, we've provided a compatibility artifact `kotlin-coroutines-experimental-compat.jar` with all the experimental coroutines APIs. We've published it to Maven, and we include it in the Kotlin distribution alongside the standard library.

Stable JSON serialization

With Kotlin 1.4.0, we are shipping the first stable version of kotlinx.serialization - 1.0.0-RC. Now we are pleased to declare the JSON serialization API in `kotlinx-serialization-core` (previously known as `kotlinx-serialization-runtime`) stable. Libraries for other serialization formats remain experimental, along with some advanced parts of the core library.

We have significantly reworked the API for JSON serialization to make it more consistent and easier to use. From now on, we'll continue developing the JSON serialization API in a backward-compatible manner. However, if you have used previous versions of it, you'll need to rewrite some of your code when migrating to 1.0.0-RC. To help you with this, we also offer the Kotlin Serialization Guide – the complete set of documentation for `kotlinx.serialization`. It will guide you through the process of using the most important features and it can help you address any issues that you might face.

Note: `kotlinx-serialization` 1.0.0-RC only works with Kotlin compiler 1.4. Earlier compiler versions are not compatible.

Scripting and REPL

In 1.4.0, scripting in Kotlin benefits from a number of functional and performance improvements along with other updates. Here are some of the key changes:

- New dependencies resolution API
- New REPL API
- Compiled scripts cache
- Artifacts renaming

To help you become more familiar with scripting in Kotlin, we've prepared a project with examples. It contains examples of the standard scripts (`*.main.kts`) and examples of uses of the Kotlin Scripting API and custom script definitions. Please give it a try and share your feedback using our issue tracker.

New dependencies resolution API

In 1.4.0, we've introduced a new API for resolving external dependencies (such as Maven artifacts), along with implementations for it. This API is published in the new artifacts `kotlin-scripting-dependencies` and `kotlin-scripting-dependencies-maven`. The previous dependency resolution functionality in `kotlin-script-util` library is now deprecated.

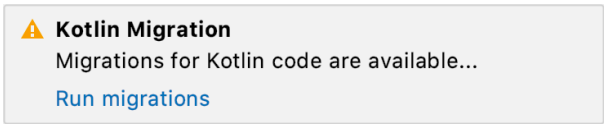
New REPL API

The new experimental REPL API is now a part of the Kotlin Scripting API. There are also several implementations of it in the published artifacts, and some have advanced functionality, such as code completion. We use this API in the Kotlin Jupyter kernel and now you can try it in your own custom shells and REPLs.

Compiled scripts cache

The Kotlin Scripting API now provides the ability to implement a compiled scripts cache, significantly speeding up subsequent executions of unchanged scripts. Our default advanced script implementation `kotlin-main-kts` already has its own cache.

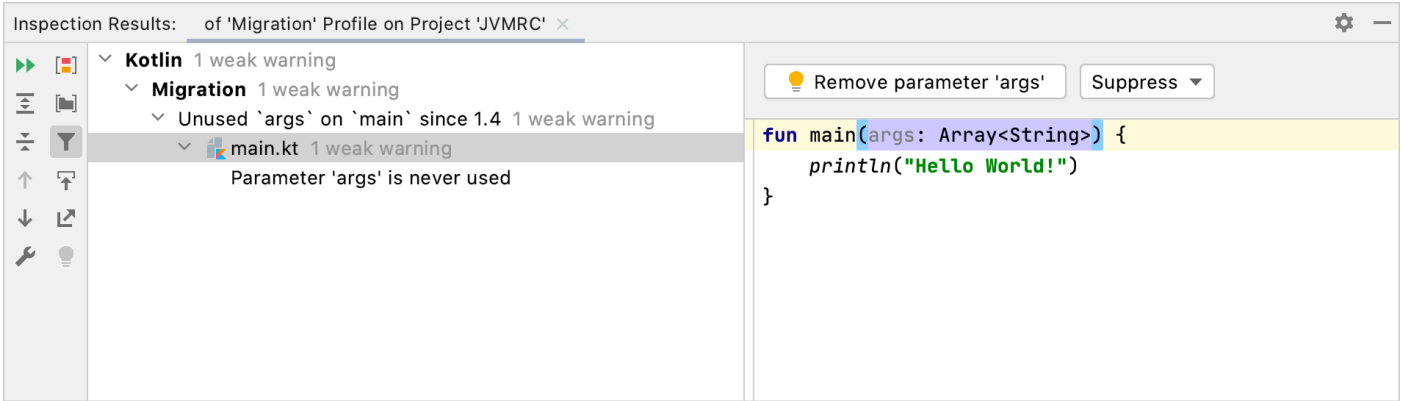
Artifacts renaming



In order to avoid confusion about artifact names, we've renamed `kotlin-scripting-jsr223-embeddable` and `kotlin-scripting-jvm-host-embeddable` to just `kotlin-scripting-jsr223` and `kotlin-scripting-jvm-host`. These artifacts depend on the `kotlin-compiler-embeddable` artifact, which shades the bundled third-party libraries to avoid usage conflicts. With this renaming, we're making the usage of `kotlin-compiler-embeddable` (which is safer in general) the default for scripting artifacts. If, for some reason, you need artifacts that depend on the unshaded `kotlin-compiler`, use the artifact versions with the `-unshaded` suffix, such as `kotlin-scripting-jsr223-unshaded`. Note that this renaming affects only the scripting artifacts that are supposed to be used directly; names of other artifacts remain unchanged.

Migrating to Kotlin 1.4.0

The Kotlin plugin's migration tools help you migrate your projects from earlier versions of Kotlin to 1.4.0.



Just change the Kotlin version to `1.4.0` and re-import your Gradle or Maven project. The IDE will then ask you about migration.

If you agree, it will run migration code inspections that will check your code and suggest corrections for anything that doesn't work or that is not recommended in 1.4.0.

Run migration

Code inspections have different severity levels, to help you decide which suggestions to accept and which to ignore.

Migration inspections

Kotlin 1.4.0 is a feature release and therefore can bring incompatible changes to the language. Find the detailed list of such changes in the Compatibility Guide for Kotlin 1.4.

Compatibility guide for Kotlin 1.4.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.3 to Kotlin 1.4.

Basic terms

In this document we introduce several kinds of compatibility:

- *source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *behavioral*: a change is said to be behavioral-incompatible if the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (for example, from Java) is out of the scope of this document.

Language and stdlib

Unexpected behavior with in infix operator and ConcurrentHashMap

Issue: KT-18053

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.4 will outlaw auto operator `contains` coming from the implementors of `java.util.Map` written in Java

Deprecation cycle:

- < 1.4: introduce warning for problematic operators at call-site
- >= 1.4: raise this warning to an error, `-XXLanguage:-ProhibitConcurrentHashMapContains` can be used to temporarily revert to pre-1.4 behavior

Prohibit access to protected members inside public inline members

Issue: KT-21178

Component: Core language

Incompatible change type: source

Short summary: Kotlin 1.4 will prohibit access to protected members from public inline members.

Deprecation cycle:

- < 1.4: introduce warning at call-site for problematic cases
- 1.4: raise this warning to an error, `-XXLanguage:-ProhibitProtectedCallFromInline` can be used to temporarily revert to pre-1.4 behavior

Contracts on calls with implicit receivers

Issue: KT-28672

Component: Core Language

Incompatible change type: behavioral

Short summary: smart casts from contracts will be available on calls with implicit receivers in 1.4

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-ContractsOnCallsWithImplicitReceiver` can be used to temporarily revert to pre-1.4 behavior

Inconsistent behavior of floating-point number comparisons

Issues: KT-22723

Component: Core language

Incompatible change type: behavioral

Short summary: since Kotlin 1.4, Kotlin compiler will use IEEE 754 standard to compare floating-point numbers

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-ProperIeee754Comparisons` can be used to temporarily revert to pre-1.4 behavior

No smart cast on the last expression in a generic lambda

Issue: KT-15020

Component: Core Language

Incompatible change type: behavioral

Short summary: smart casts for last expressions in lambdas will be correctly applied since 1.4

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Do not depend on the order of lambda arguments to coerce result to Unit

Issue: KT-36045

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, lambda arguments will be resolved independently without implicit coercion to `Unit`

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Wrong common supertype between raw and integer literal type leads to unsound code

Issue: KT-35681

Components: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, common supertype between raw `Comparable` type and integer literal type will be more specific

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Type safety problem because several equal type variables are instantiated with a different types

Issue: KT-35679

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, Kotlin compiler will prohibit instantiating equal type variables with different types

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Type safety problem because of incorrect subtyping for intersection types

Issues: KT-22474

Component: Core language

Incompatible change type: source

Short summary: in Kotlin 1.4, subtyping for intersection types will be refined to work more correctly

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

No type mismatch with an empty when expression inside lambda

Issue: KT-17995

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, there will be a type mismatch for empty `when` expression if it's used as the last expression in a lambda

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Return type Any inferred for lambda with early return with integer literal in one of possible return values

Issue: KT-20226

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, integer type returning from a lambda will be more specific for cases when there is early return

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Proper capturing of star projections with recursive types

Issue: KT-33012

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, more candidates will become applicable because capturing for recursive types will work more correctly

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Common supertype calculation with non-proper type and flexible one leads to incorrect results

Issue: KT-37054

Component: Core language

Incompatible change type: behavioral

Short summary: since Kotlin 1.4, common supertype between flexible types will be more specific protecting from runtime errors

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Type safety problem because of lack of captured conversion against nullable type argument

Issue: KT-35487

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, subtyping between captured and nullable types will be more correct protecting from runtime errors

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Preserve intersection type for covariant types after unchecked cast

Issue: KT-37280

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, uchecked casts of covariant types produce the intersection type for smart casts, not the type of the unchecked cast.

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Type variable leaks from builder inference because of using this expression

Issue: KT-32126

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, using `this` inside builder functions like `sequence {}` is prohibited if there are no other proper constraints

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Wrong overload resolution for contravariant types with nullable type arguments

Issue: KT-31670

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, if two overloads of a function that takes contravariant type arguments differ only by the nullability of the type (such as `In<T>` and `In<T?>`), the nullable type is considered more specific.

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Builder inference with non-nested recursive constraints

Issue: KT-34975

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, builder functions such as `sequence {}` with type that depends on a recursive constraint inside the passed lambda cause a compiler error.

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Eager type variable fixation leads to a contradictory constraint system

Issue: KT-25175

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, the type inference in certain cases works less eagerly allowing to find the constraint system that is not contradictory.

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-NewInference` can be used to temporarily revert to pre-1.4 behavior. Note that this flag will also disable several new language features.

Prohibit tailrec modifier on open functions

Issue: KT-18541

Component: Core language

Incompatible change type: source

Short summary: since Kotlin 1.4, functions can't have `open` and `tailrec` modifiers at the same time.

Deprecation cycle:

- < 1.4: report a warning on functions that have `open` and `tailrec` modifiers together (error in the progressive mode).
- >= 1.4: raise this warning to an error.

The INSTANCE field of a companion object more visible than the companion object class itself

Issue: KT-11567

Component: Kotlin/JVM

Incompatible change type: source

Short summary: since Kotlin 1.4, if a companion object is private, then its field `INSTANCE` will be also private

Deprecation cycle:

- < 1.4: the compiler generates object `INSTANCE` with a deprecated flag
- >= 1.4: companion object `INSTANCE` field has proper visibility

Outer finally block inserted before return is not excluded from the catch interval of the inner try block without finally

Issue: KT-31923

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: since Kotlin 1.4, the catch interval will be computed properly for nested `try/catch` blocks

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-ProperFinally` can be used to temporarily revert to pre-1.4 behavior

Use the boxed version of an inline class in return type position for covariant and generic-specialized overrides

Issues: KT-30419

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: since Kotlin 1.4, functions using covariant and generic-specialized overrides will return boxed values of inline classes

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

Do not declare checked exceptions in JVM bytecode when using delegation to Kotlin interfaces

Issue: KT-35834

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.4 will not generate checked exceptions during interface delegation to Kotlin interfaces

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-DoNotGenerateThrowsForDelegatedKotlinMembers` can be used to temporarily revert to pre-1.4 behavior

Changed behavior of signature-polymorphic calls to methods with a single vararg parameter to avoid wrapping the argument into another array

Issue: KT-35469

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.4 will not wrap the argument into another array on a signature-polymorphic call

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

Incorrect generic signature in annotations when KClass is used as a generic parameter

Issue: KT-35207

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.4 will fix incorrect type mapping in annotations when KClass is used as a generic parameter

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

Forbid spread operator in signature-polymorphic calls

Issue: KT-35226

Component: Kotlin/JVM

Incompatible change type: source

Short summary: Kotlin 1.4 will prohibit the use of spread operator (*) on signature-polymorphic calls

Deprecation cycle:

- < 1.4: report a warning on the use of a spread operator in signature-polymorphic calls
- >= 1.5: raise this warning to an error, `-XXLanguage:-ProhibitSpreadOnSignaturePolymorphicCall` can be used to temporarily revert to pre-1.4 behavior

Change initialization order of default values for tail-recursive optimized functions

Issue: KT-31540

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Since Kotlin 1.4, the initialization order for tail-recursive functions will be the same as for regular functions

Deprecation cycle:

- < 1.4: report a warning at declaration-site for problematic functions
- >= 1.4: behavior changed, `-XXLanguage:-ProperComputationOrderOfTailrecDefaultParameters` can be used to temporarily revert to pre-1.4 behavior

Do not generate ConstantValue attribute for non-const vals

Issue: KT-16615

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: Since Kotlin 1.4, the compiler will not generate the `ConstantValue` attribute for non-`const` `val`s

Deprecation cycle:

- < 1.4: report a warning through an IntelliJ IDEA inspection
- >= 1.4: behavior changed, `-XXLanguage:-NoConstantValueAttributeForNonConstVals` can be used to temporarily revert to pre-1.4 behavior

Generated overloads for @JvmOverloads on open methods should be final

Issue: KT-33240

Components: Kotlin/JVM

Incompatible change type: source

Short summary: overloads for functions with `@JvmOverloads` will be generated as `final`

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed, `-XXLanguage:-GenerateJvmOverloadsAsFinal` can be used to temporarily revert to pre-1.4 behavior

Lambdas returning kotlin.Result now return boxed value instead of unboxed

Issue: KT-39198

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: since Kotlin 1.4, lambdas returning values of `kotlin.Result` type will return boxed value instead of unboxed

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

Unify exceptions from null checks

Issue: KT-22275

Component: Kotlin/JVM

Incompatible change type: behavior

Short summary: Starting from Kotlin 1.4, all runtime null checks will throw a `java.lang.NullPointerException`

Deprecation cycle:

- < 1.4: runtime null checks throw different exceptions, such as `KotlinNullPointerException`, `IllegalStateException`, `IllegalArgumentException`, and `TypeCastException`
- >= 1.4: all runtime null checks throw a `java.lang.NullPointerException`. `-Xno-unified-null-checks` can be used to temporarily revert to pre-1.4 behavior

Comparing floating-point values in array/list operations contains, indexOf, lastIndexOf: IEEE 754 or total order

Issue: KT-28753

Component: kotlin-stdlib (JVM)

Incompatible change type: behavioral

Short summary: the `List` implementation returned from `Double/FloatArray.asList()` will implement `contains`, `indexOf`, and `lastIndexOf`, so that they use total order equality

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

Gradually change the return type of collection min and max functions to non-nullable

Issue: KT-38854

Component: kotlin-stdlib (JVM)

Incompatible change type: source

Short summary: return type of collection `min` and `max` functions will be changed to non-nullable in 1.6

Deprecation cycle:

- 1.4: introduce `...OrNull` functions as synonyms and deprecate the affected API (see details in the issue)
- 1.5.x: raise the deprecation level of the affected API to error
- >=1.6: reintroduce the affected API but with non-nullable return type

Deprecate appendln in favor of appendLine

Issue: KT-38754

Component: kotlin-stdlib (JVM)

Incompatible change type: source

Short summary: `StringBuilder.appendln()` will be deprecated in favor of `StringBuilder.appendLine()`

Deprecation cycle:

- 1.4: introduce `appendLine` function as a replacement for `appendln` and deprecate `appendln`
- >=1.5: raise the deprecation level to error

Deprecate conversions of floating-point types to Short and Byte

Issue: KT-30360

Component: kotlin-stdlib (JVM)

Incompatible change type: source

Short summary: since Kotlin 1.4, conversions of floating-point types to `Short` and `Byte` will be deprecated

Deprecation cycle:

- 1.4: deprecate `Double.toShort()/toByte()` and `Float.toShort()/toByte()` and propose replacement
- >=1.5: raise the deprecation level to error

Fail fast in Regex.findAll on an invalid startIndex

Issue: KT-28356

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: since Kotlin 1.4, `findAll` will be improved to check that `startIndex` is in the range of the valid position indices of the input char sequence at the moment of entering `findAll`, and throw `IndexOutOfBoundsException` if it's not

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

Remove deprecated kotlin.coroutines.experimental

Issue: KT-36083

Component: kotlin-stdlib

Incompatible change type: source

Short summary: since Kotlin 1.4, the deprecated `kotlin.coroutines.experimental` API is removed from stdlib

Deprecation cycle:

- < 1.4: `kotlin.coroutines.experimental` is deprecated with the `ERROR` level
- >= 1.4: `kotlin.coroutines.experimental` is removed from stdlib. On the JVM, a separate compatibility artifact is provided (see details in the issue).

Remove deprecated mod operator

Issue: KT-26654

Component: kotlin-stdlib

Incompatible change type: source

Short summary: since Kotlin 1.4, `mod` operator on numeric types is removed from stdlib

Deprecation cycle:

- < 1.4: `mod` is deprecated with the `ERROR` level
- >= 1.4: `mod` is removed from stdlib

Hide Throwable.addSuppressed member and prefer extension instead

Issue: KT-38777

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: `Throwable.addSuppressed()` extension function is now preferred over the `Throwable.addSuppressed()` member function

Deprecation cycle:

- < 1.4: old behavior (see details in the issue)
- >= 1.4: behavior changed

capitalize should convert digraphs to title case

Issue: KT-38817

Component: kotlin-stdlib

Incompatible change type: behavioral

Short summary: `String.capitalize()` function now capitalizes digraphs from the Serbo-Croatian Gaj's Latin alphabet in the title case (`Dž` instead of `DŽ`)

Deprecation cycle:

- < 1.4: digraphs are capitalized in the upper case (`DŽ`)
- >= 1.4: digraphs are capitalized in the title case (`Dž`)

Tools

Compiler arguments with delimiter characters must be passed in double quotes on Windows

Issue: KT-41309

Component: CLI

Incompatible change type: behavioral

Short summary: on Windows, `kotlinc.bat` arguments that contain delimiter characters (whitespace, `=` , `;` , `,`) now require double quotes (`"`)

Deprecation cycle:

- < 1.4: all compiler arguments are passed without quotes
- >= 1.4: compiler arguments that contain delimiter characters (whitespace, `=` , `;` , `,`) require double quotes (`"`)

KAPT: Names of synthetic $annotations() methods for properties have changed

Issue: KT-36926

Component: KAPT

Incompatible change type: behavioral

Short summary: names of synthetic `$annotations()` methods generated by KAPT for properties have changed in 1.4

Deprecation cycle:

- < 1.4: names of synthetic `$annotations()` methods for properties follow the template `<propertyName>@annotations()`
- >= 1.4: names of synthetic `$annotations()` methods for properties include the `get` prefix: `get<PropertyName>@annotations()`

What's new in Kotlin 1.3

Released: 29 October 2018

For information about the Kotlin release cycle, see Kotlin release process.

Coroutines release

After some long and extensive battle testing, coroutines are now released! It means that from Kotlin 1.3 the language support and the API are fully stable. Check out the new coroutines overview page.

Kotlin 1.3 introduces callable references on suspend-functions and support of coroutines in the reflection API.

Kotlin/Native

Kotlin 1.3 continues to improve and polish the Native target. See the Kotlin/Native overview for details.

Multiplatform projects

In 1.3, we've completely reworked the model of multiplatform projects in order to improve expressiveness and flexibility, and to make sharing common code easier. Also, Kotlin/Native is now supported as one of the targets!

The key differences to the old model are:

- In the old model, common and platform-specific code needed to be placed in separate modules, linked by `expectedBy` dependencies. Now, common and platform-specific code is placed in different source roots of the same module, making projects easier to configure.
- There is now a large number of preset platform configurations for different supported platforms.
- The dependencies configuration has been changed; dependencies are now specified separately for each source root.

- Source sets can now be shared between an arbitrary subset of platforms (for example, in a module that targets JS, Android and iOS, you can have a source set that is shared only between Android and iOS).
- Publishing multiplatform libraries is now supported.

For more information, please refer to the multiplatform programming documentation.

Contracts

The Kotlin compiler does extensive static analysis to provide warnings and reduce boilerplate. One of the most notable features is smartcasts — with the ability to perform a cast automatically based on the performed type checks:

```
fun foo(s: String?) {
    if (s ≠ null) s.length // Compiler automatically casts 's' to 'String'
}
```

However, as soon as these checks are extracted in a separate function, all the smartcasts immediately disappear:

```
fun String?.isNotNull(): Boolean = this ≠ null

fun foo(s: String?) {
    if (s.isNotNull()) s.length // No smartcast :(
}
```

To improve the behavior in such cases, Kotlin 1.3 introduces experimental mechanism called *contracts*.

Contracts allow a function to explicitly describe its behavior in a way which is understood by the compiler. Currently, two wide classes of cases are supported:

- Improving smartcasts analysis by declaring the relation between a function's call outcome and the passed arguments values:

```
fun require(condition: Boolean) {
    // This is a syntax form which tells the compiler:
    // "if this function returns successfully, then the passed 'condition' is true"
    contract { returns() implies condition }
    if (!condition) throw IllegalArgumentException(...)
}

fun foo(s: String?) {
    require(s is String)
    // s is smartcast to 'String' here, because otherwise
    // 'require' would have thrown an exception
}
```

- Improving the variable initialization analysis in the presence of higher-order functions:

```
fun synchronize(lock: Any?, block: () → Unit) {
    // It tells the compiler:
    // "This function will invoke 'block' here and now, and exactly one time"
    contract { callsInPlace(block, EXACTLY_ONCE) }
}

fun foo() {
    val x: Int
    synchronize(lock) {
        x = 42 // Compiler knows that lambda passed to 'synchronize' is called
               // exactly once, so no reassignment is reported
    }
    println(x) // Compiler knows that lambda will be definitely called, performing
               // initialization, so 'x' is considered to be initialized here
}
```

Contracts in stdlib

`stdlib` already makes use of contracts, which leads to improvements in the analyses described above. This part of contracts is **stable**, meaning that you can benefit from the improved analysis right now without any additional opt-ins:

```
fun bar(x: String?) {
    if (!x.isNullOrEmpty()) {
        println("length of '$x' is ${x.length}") // Yay, smartcast to not-null!
    }
}
fun main() {
    bar(null)
    bar("42")
}
```

Custom contracts

It is possible to declare contracts for your own functions, but this feature is **experimental,** as the current syntax is in a state of early prototype and will most probably be changed. Also please note that currently the Kotlin compiler does not verify contracts, so it's the responsibility of the programmer to write correct and sound contracts.

Custom contracts are introduced by a call to `contract` stdlib function, which provides DSL scope:

```
fun String?.isNullOrEmpty(): Boolean {
    contract {
        returns(false) implies (this@isNullOrEmpty ≠ null)
    }
    return this == null || isEmpty()
}
```

See the details on the syntax as well as the compatibility notice in the KEEP.

Capturing when subject in a variable

In Kotlin 1.3, it is now possible to capture the `when` subject into a variable:

```
fun Request.getBody() =
        when (val response = executeRequest()) {
            is Success -> response.body
            is HttpError -> throw HttpException(response.status)
        }
```

While it was already possible to extract this variable just before `when`, `val` in `when` has its scope properly restricted to the body of `when`, and so preventing namespace pollution. See the full documentation on `when` here.

@JvmStatic and @JvmField in companions of interfaces

With Kotlin 1.3, it is possible to mark members of a `companion` object of interfaces with annotations `@JvmStatic` and `@JvmField`. In the classfile, such members will be lifted to the corresponding interface and marked as `static`.

For example, the following Kotlin code:

```
interface Foo {
    companion object {
        @JvmField
        val answer: Int = 42

        @JvmStatic
        fun sayHello() {
            println("Hello, world!")
        }
    }
}
```

It is equivalent to this Java code:

```
interface Foo {
    public static int answer = 42;
    public static void sayHello() {
        // ...
    }
}
```

Nested declarations in annotation classes

In Kotlin 1.3, it is possible for annotations to have nested classes, interfaces, objects, and companions:

```
annotation class Foo {
    enum class Direction { UP, DOWN, LEFT, RIGHT }

    annotation class Bar

    companion object {
        fun foo(): Int = 42
        val bar: Int = 42
    }
}
```

Parameterless main

By convention, the entry point of a Kotlin program is a function with a signature like `main(args: Array<String>)`, where `args` represent the command-line arguments passed to the program. However, not every application supports command-line arguments, so this parameter often ends up not being used.

Kotlin 1.3 introduced a simpler form of `main` which takes no parameters. Now "Hello, World" in Kotlin is 19 characters shorter!

```
fun main() {
    println("Hello, world!")
}
```

Functions with big arity

In Kotlin, functional types are represented as generic classes taking a different number of parameters: `Function0<R>`, `Function1<P0, R>`, `Function2<P0, P1, R>`, ... This approach has a problem in that this list is finite, and it currently ends with `Function22`.

Kotlin 1.3 relaxes this limitation and adds support for functions with bigger arity:

```
fun trueEnterpriseComesToKotlin(block: (Any, Any, ... /* 42 more */, Any) -> Any) {
    block(Any(), Any(), ..., Any())
}
```

Progressive mode

Kotlin cares a lot about stability and backward compatibility of code: Kotlin compatibility policy says that breaking changes (e.g., a change which makes the code that used to compile fine, not compile anymore) can be introduced only in the major releases (**1.2**, **1.3**, etc.).

We believe that a lot of users could use a much faster cycle where critical compiler bug fixes arrive immediately, making the code more safe and correct. So, Kotlin 1.3 introduces the *progressive* compiler mode, which can be enabled by passing the argument `-progressive` to the compiler.

In the progressive mode, some fixes in language semantics can arrive immediately. All these fixes have two important properties:

- They preserve backward compatibility of source code with older compilers, meaning that all the code which is compilable by the progressive compiler will be compiled fine by non-progressive one.
- They only make code *safer* in some sense — e.g., some unsound smartcast can be forbidden, behavior of the generated code may be changed to be more predictable/stable, and so on.

Enabling the progressive mode can require you to rewrite some of your code, but it shouldn't be too much — all the fixes enabled under progressive are carefully handpicked, reviewed, and provided with tooling migration assistance. We expect that the progressive mode will be a nice choice for any actively maintained codebases which are updated to the latest language versions quickly.

Inline classes

Inline classes are in Alpha. They may change incompatibly and require manual migration in the future. We appreciate your feedback on it in YouTrack. See details in the reference.

Kotlin 1.3 introduces a new kind of declaration — `inline class`. Inline classes can be viewed as a restricted version of the usual classes, in particular, inline classes must have exactly one property:

```
inline class Name(val s: String)
```

The Kotlin compiler will use this restriction to aggressively optimize runtime representation of inline classes and substitute their instances with the value of the underlying property where possible removing constructor calls, GC pressure, and enabling other optimizations:

```
inline class Name(val s: String)
fun main() {
    // In the next line no constructor call happens, and
    // at the runtime 'name' contains just string "Kotlin"
    val name = Name("Kotlin")
    println(name.s)
}
```

See reference for inline classes for details.

Unsigned integers

Unsigned integers are in Beta. Their implementation is almost stable, but migration steps may be required in the future. We'll do our best to minimize any changes you will have to make.

Kotlin 1.3 introduces unsigned integer types:

- `kotlin.UByte` : an unsigned 8-bit integer, ranges from 0 to 255
- `kotlin.UShort` : an unsigned 16-bit integer, ranges from 0 to 65535
- `kotlin.UInt` : an unsigned 32-bit integer, ranges from 0 to 2^32 - 1
- `kotlin.ULong` : an unsigned 64-bit integer, ranges from 0 to 2^64 - 1

Most of the functionality of signed types are supported for unsigned counterparts too:

```
fun main() {
// You can define unsigned types using literal suffixes
val uint = 42u
val ulong = 42uL
val ubyte: UByte = 255u

// You can convert signed types to unsigned and vice versa via stdlib extensions:
val int = uint.toInt()
val byte = ubyte.toByte()
val ulong2 = byte.toULong()

// Unsigned types support similar operators:
val x = 20u + 22u
val y = 1u shl 8
val z = "128".toUByte()
val range = 1u..5u
println("ubyte: $ubyte, byte: $byte, ulong2: $ulong2")
println("x: $x, y: $y, z: $z, range: $range")
}
```

See reference for details.

@JvmDefault

`@JvmDefault` is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

Kotlin targets a wide range of the Java versions, including Java 6 and Java 7, where default methods in the interfaces are not allowed. For your convenience, the Kotlin compiler works around that limitation, but this workaround isn't compatible with the `default` methods, introduced in Java 8.

This could be an issue for Java-interoperability, so Kotlin 1.3 introduces the `@JvmDefault` annotation. Methods annotated with this annotation will be generated as `default` methods for JVM:

```
interface Foo {
    // Will be generated as 'default' method
    @JvmDefault
    fun foo(): Int = 42
}
```

Warning! Annotating your API with `@JvmDefault` has serious implications on binary compatibility. Make sure to carefully read the reference page before using `@JvmDefault` in production.

Standard library

Multiplatform random

Prior to Kotlin 1.3, there was no uniform way to generate random numbers on all platforms — we had to resort to platform-specific solutions like `java.util.Random` on JVM. This release fixes this issue by introducing the class `kotlin.random.Random`, which is available on all platforms:

```
import kotlin.random.Random

fun main() {
    val number = Random.nextInt(42)  // number is in range [0, limit)
    println(number)
}
```

isNullOrEmpty and orEmpty extensions

`isNullOrEmpty` and `orEmpty` extensions for some types are already present in stdlib. The first one returns `true` if the receiver is `null` or empty, and the second one falls back to an empty instance if the receiver is `null`. Kotlin 1.3 provides similar extensions on collections, maps, and arrays of objects.

Copy elements between two existing arrays

The `array.copyInto(targetArray, targetOffset, startIndex, endIndex)` functions for the existing array types, including the unsigned arrays, make it easier to implement array-based containers in pure Kotlin.

```
fun main() {
    val sourceArr = arrayOf("k", "o", "t", "l", "i", "n")
    val targetArr = sourceArr.copyInto(arrayOfNulls<String>(6), 3, startIndex = 3, endIndex = 6)
    println(targetArr.contentToString())

    sourceArr.copyInto(targetArr, startIndex = 0, endIndex = 3)
    println(targetArr.contentToString())
}
```

associateWith

It is quite a common situation to have a list of keys and want to build a map by associating each of these keys with some value. It was possible to do it before with the `associate { it to getValue(it) }` function, but now we're introducing a more efficient and easy to explore alternative: `keys.associateWith { getValue(it) }`.

```
fun main() {
    val keys = 'a'..'f'
    val map = keys.associateWith { it.toString().repeat(5).capitalize() }
    map.forEach { println(it) }
}
```

ifEmpty and ifBlank functions

Collections, maps, object arrays, char sequences, and sequences now have an `ifEmpty` function, which allows specifying a fallback value that will be used instead of the receiver if it is empty:

```
fun main() {
    fun printAllUppercase(data: List<String>) {
        val result = data
        .filter { it.all { c -> c.isUpperCase() } }
            .ifEmpty { listOf("<no uppercase>") }
        result.forEach { println(it) }
    }

    printAllUppercase(listOf("foo", "Bar"))
    printAllUppercase(listOf("FOO", "BAR"))
}
```

Char sequences and strings in addition have an `ifBlank` extension that does the same thing as `ifEmpty` but checks for a string being all whitespace instead of empty.

```
fun main() {
    val s = "    \n"
    println(s.ifBlank { "<blank>" })
    println(s.ifBlank { null })
}
```

Sealed classes in reflection

We've added a new API to `kotlin-reflect` that can be used to enumerate all the direct subtypes of a `sealed` class, namely `KClass.sealedSubclasses`.

Smaller changes

- `Boolean` type now has companion.
- `Any?.hashCode()` extension that returns 0 for `null`.
- `Char` now provides `MIN_VALUE` and `MAX_VALUE` constants.
- `SIZE_BYTES` and `SIZE_BITS` constants in primitive type companions.

Tooling

Code style support in IDE

Kotlin 1.3 introduces support for the recommended code style in IntelliJ IDEA. Check out this page for the migration guidelines.

kotlinx.serialization

kotlinx.serialization is a library which provides multiplatform support for (de)serializing objects in Kotlin. Previously, it was a separate project, but since Kotlin 1.3, it ships with the Kotlin compiler distribution on par with the other compiler plugins. The main difference is that you don't need to manually watch out for the Serialization IDE Plugin being compatible with the Kotlin IDE plugin version you're using: now the Kotlin IDE plugin already includes serialization!

See here for details.

Even though kotlinx.serialization now ships with the Kotlin Compiler distribution, it is still considered to be an experimental feature in Kotlin 1.3.

Scripting update

Scripting is Experimental. It may be dropped or changed at any time. Use it only for evaluation purposes. We appreciate your feedback on it in YouTrack.

Kotlin 1.3 continues to evolve and improve scripting API, introducing some experimental support for scripts customization, such as adding external properties, providing static or dynamic dependencies, and so on.

For additional details, please consult the KEEP-75.

Scratches support

Kotlin 1.3 introduces support for runnable Kotlin *scratch files*. *Scratch file* is a kotlin script file with the .kts extension that you can run and get evaluation results directly in the editor.

Consult the general Scratches documentation for details.

Compatibility guide for Kotlin 1.3.x

Keeping the Language Modern and *Comfortable Updates* are among the fundamental principles in Kotlin Language Design. The former says that constructs which obstruct language evolution should be removed, and the latter says that this removal should be well-communicated beforehand to make code migration as smooth as possible.

While most of the language changes were already announced through other channels, like update changelogs or compiler warnings, this document summarizes them all, providing a complete reference for migration from Kotlin 1.2 to Kotlin 1.3.

Basic terms

In this document we introduce several kinds of compatibility:

- *Source*: source-incompatible change stops code that used to compile fine (without errors or warnings) from compiling anymore
- *Binary*: two binary artifacts are said to be binary-compatible if interchanging them doesn't lead to loading or linkage errors
- *Behavioral*: a change is said to be behavioral-incompatible if one and the same program demonstrates different behavior before and after applying the change

Remember that those definitions are given only for pure Kotlin. Compatibility of Kotlin code from the other languages perspective (e.g. from Java) is out of the scope of this document.

Incompatible changes

Evaluation order of constructor arguments regarding <clinit> call

Issue: KT-19532

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: evaluation order with respect to class initialization is changed in 1.3

Deprecation cycle:

- <1.3: old behavior (see details in the Issue)
- >= 1.3: behavior changed, `-Xnormalize-constructor-calls=disable` can be used to temporarily revert to pre-1.3 behavior. Support for this flag is going to be removed in the next major release.

Missing getter-targeted annotations on annotation constructor parameters

Issue: KT-25287

Component: Kotlin/JVM

Incompatible change type: behavioral

Short summary: getter-target annotations on annotations constructor parameters will be properly written to classfiles in 1.3

Deprecation cycle:

- <1.3: getter-target annotations on annotation constructor parameters are not applied
- >=1.3: getter-target annotations on annotation constructor parameters are properly applied and written to the generated code

Missing errors in class constructor's @get: annotations

Issue: KT-19628

Component: Core language

Incompatible change type: Source

Short summary: errors in getter-target annotations will be reported properly in 1.3

Deprecation cycle:

- <1.2: compilation errors in getter-target annotations were not reported, causing incorrect code to be compiled fine.
- 1.2.x: errors reported only by tooling, the compiler still compiles such code without any warnings
- >=1.3: errors reported by the compiler too, causing erroneous code to be rejected

Nullability assertions on access to Java types annotated with @NotNull

Issue: KT-20830

Component: Kotlin/JVM

Incompatible change type: Behavioral

Short summary: nullability assertions for Java-types annotated with not-null annotations will be generated more aggressively, causing code which passes `null` here to fail faster.

Deprecation cycle:

- <1.3: the compiler could miss such assertions when type inference was involved, allowing potential `null` propagation during compilation against binaries (see Issue for details).
- >=1.3: the compiler generates missed assertions. This can cause code which was (erroneously) passing `null`s here fail faster.
  `-XXLanguage:-StrictJavaNullabilityAssertions` can be used to temporarily return to the pre-1.3 behavior. Support for this flag will be removed in the next major release.

Unsound smartcasts on enum members

Issue: KT-20772

Component: Core language

Incompatible change type: Source

Short summary: a smartcast on a member of one enum entry will be correctly applied to only this enum entry

Deprecation cycle:

- <1.3: a smartcast on a member of one enum entry could lead to an unsound smartcast on the same member of other enum entries.
- >=1.3: smartcast will be properly applied only to the member of one enum entry.
  `-XXLanguage:-SoundSmartcastForEnumEntries` will temporarily return old behavior. Support for this flag will be removed in the next major release.

val backing field reassignment in getter

Issue: KT-16681

Components: Core language

Incompatible change type: Source

Short summary: reassignment of the backing field of `val`-property in its getter is now prohibited

Deprecation cycle:

- <1.2: Kotlin compiler allowed to modify backing field of `val` in its getter. Not only it violates Kotlin semantic, but also generates ill-behaved JVM bytecode which reassigns `final` field.
- 1.2.X: deprecation warning is reported on code which reassigns backing field of `val`
- >=1.3: deprecation warnings are elevated to errors

Array capturing before the for-loop where it is iterated

Issue: KT-21354

Component: Kotlin/JVM

Incompatible change type: Source

Short summary: if an expression in for-loop range is a local variable updated in a loop body, this change affects loop execution. This is inconsistent with iterating over other containers, such as ranges, character sequences, and collections.

Deprecation cycle:

- <1.2: described code patterns are compiled fine, but updates to local variable affect loop execution
- 1.2.X: deprecation warning reported if a range expression in a for-loop is an array-typed local variable which is assigned in a loop body
- 1.3: change behavior in such cases to be consistent with other containers

Nested classifiers in enum entries

Issue: KT-16310

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, nested classifiers (classes, object, interfaces, annotation classes, enum classes) in enum entries are prohibited

Deprecation cycle:

- <1.2: nested classifiers in enum entries are compiled fine, but may fail with exception at runtime
- 1.2.X: deprecation warnings reported on the nested classifiers
- >=1.3: deprecation warnings elevated to errors

Data class overriding copy

Issue: KT-19618

Components: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, data classes are prohibited to override `copy()`

Deprecation cycle:

- <1.2: data classes overriding `copy()` are compiled fine but may fail at runtime/expose strange behavior
- 1.2.X: deprecation warnings reported on data classes overriding `copy()`
- >=1.3: deprecation warnings elevated to errors

Inner classes inheriting Throwable that capture generic parameters from the outer class

Issue: KT-17981

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, inner classes are not allowed to inherit `Throwable`

Deprecation cycle:

- <1.2: inner classes inheriting `Throwable` are compiled fine. If such inner classes happen to capture generic parameters, it could lead to strange code patterns which fail at runtime.
- 1.2.X: deprecation warnings reported on inner classes inheriting `Throwable`
- >=1.3: deprecation warnings elevated to errors

Visibility rules regarding complex class hierarchies with companion objects

Issues: KT-21515, KT-25333

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, rules of visibility by short names are stricter for complex class hierarchies involving companion objects and nested classifiers.

Deprecation cycle:

- <1.2: old visibility rules (see Issue for details)
- 1.2.X: deprecation warnings reported on short names which are not going to be accessible anymore. Tooling suggests automated migration by adding full name.
- >=1.3: deprecation warnings elevated to errors. Offending code should add full qualifiers or explicit imports

Non-constant vararg annotation parameters

Issue: KT-23153

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, setting non-constant values as vararg annotation parameters is prohibited

Deprecation cycle:

- <1.2: the compiler allows to pass non-constant value for vararg annotation parameter, but actually drops that value during bytecode generation, leading to non-obvious behavior
- 1.2.X: deprecation warnings reported on such code patterns
- >=1.3: deprecation warnings elevated to errors

Local annotation classes

Issue: KT-23277

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3 local annotation classes are not supported

Deprecation cycle:

- <1.2: the compiler compiled local annotation classes fine
- 1.2.X: deprecation warnings reported on local annotation classes
- >=1.3: deprecation warnings elevated to errors

Smartcasts on local delegated properties

Issue: KT-22517

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3 smartcasts on local delegated properties are not allowed

Deprecation cycle:

- <1.2: the compiler allowed to smartcast local delegated property, which could lead to unsound smartcast in case of ill-behaved delegates
- 1.2.X: smartcasts on local delegated properries are reported as deprecated (the compiler issues warnings)
- >=1.3: deprecation warnings elevated to errors

mod operator convention

Issues: KT-24197

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3 declaration of `mod` operator is prohibited, as well as calls which resolve to such declarations

Deprecation cycle:

- 1.1.X, 1.2.X: report warnings on declarations of `operator mod`, as well as on calls which resolve to it
- 1.3.X: elevate warnings to error, but still allow to resolve to `operator mod` declarations
- 1.4.X: do not resolve calls to `operator mod` anymore

Passing single element to vararg in named form

Issues: KT-20588, KT-20589. See also KT-20171

Component: Core language

Incompatible change type: Source

Short summary: in Kotlin 1.3, assigning single element to vararg is deprecated and should be replaced with consecutive spread and array construction.

Deprecation cycle:

- <1.2: assigning one value element to vararg in named form compiles fine and is treated as assigning *single* element to array, causing non-obvious behavior when assigning array to vararg
- 1.2.X: deprecation warnings are reported on such assignments, users are suggested to switch to consecutive spread and array construction.
- 1.3.X: warnings are elevated to errors
- >= 1.4: change semantic of assigning single element to vararg, making assignment of array equivalent to the assignment of a spread of an array

Retention of annotations with target EXPRESSION

Issue: KT-13762

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, only `SOURCE` retention is allowed for annotations with target `EXPRESSION`

Deprecation cycle:

- <1.2: annotations with target `EXPRESSION` and retention other than `SOURCE` are allowed, but silently ignored at use-sites
- 1.2.X: deprecation warnings are reported on declarations of such annotations
- >=1.3: warnings are elevated to errors

Annotations with target PARAMETER shouldn't be applicable to parameter's type

Issue: KT-9580

Component: Core language

Incompatible change type: Source

Short summary: since Kotlin 1.3, error about wrong annotation target will be properly reported when annotation with target `PARAMETER` is applied to parameter's type

Deprecation cycle:

- <1.2: aforementioned code patterns are compiled fine; annotations are silently ignored and not present in the bytecode
- 1.2.X: deprecation warnings are reported on such usages
- >=1.3: warnings are elevated to errors

Array.copyOfRange throws an exception when indices are out of bounds instead of enlarging the returned array

Issue: KT-19489

Component: kotlin-stdlib (JVM)

Incompatible change type: Behavioral

Short summary: since Kotlin 1.3, ensure that the `toIndex` argument of `Array.copyOfRange`, which represents the exclusive end of the range being copied, is not greater than the array size and throw `IllegalArgumentException` if it is.

Deprecation cycle:

- <1.3: in case `toIndex` in the invocation of `Array.copyOfRange` is greater than the array size, the missing elements in range fill be filled with `null` s, violating soundness of the Kotlin type system.
- >=1.3: check that `toIndex` is in the array bounds, and throw exception if it isn't

Progressions of ints and longs with a step of Int.MIN_VALUE and Long.MIN_VALUE are outlawed and won't be allowed to be instantiated

Issue: KT-17176

Component: kotlin-stdlib (JVM)

Incompatible change type: Behavioral

Short summary: since Kotlin 1.3, prohibit step value for integer progressions being the minimum negative value of its integer type (`Long` or `Int`), so that calling `IntProgression.fromClosedRange(0, 1, step = Int.MIN_VALUE)` will throw `IllegalArgumentException`

Deprecation cycle:

- <1.3: it was possible to create an `IntProgression` with `Int.MIN_VALUE` step, which yields two values `[0, -2147483648]` , which is non-obvious behavior
- >=1.3: throw `IllegalArgumentException` if the step is the minimum negative value of its integer type

Check for index overflow in operations on very long sequences

Issue: KT-16097

Component: kotlin-stdlib (JVM)

Incompatible change type: Behavioral

Short summary: since Kotlin 1.3, make sure `index` , `count` and similar methods do not overflow for long sequences. See the Issue for the full list of affected methods.

Deprecation cycle:

- <1.3: calling such methods on very long sequences could produce negative results due to integer overflow
- >=1.3: detect overflow in such methods and throw exception immediately

Unify split by an empty match regex result across the platforms

Issue: KT-21049

Component: kotlin-stdlib (JVM)

Incompatible change type: Behavioral

Short summary: since Kotlin 1.3, unify behavior of `split` method by empty match regex across all platforms

Deprecation cycle:

- <1.3: behavior of described calls is different when comparing JS, JRE 6, JRE 7 versus JRE 8+
- >=1.3: unify behavior across the platforms

Discontinued deprecated artifacts in the compiler distribution

Issue: KT-23799

Component: other

Incompatible change type: Binary

Short summary: Kotlin 1.3 discontinues the following deprecated binary artifacts:

- `kotlin-runtime`: use `kotlin-stdlib` instead
- `kotlin-stdlib-jre7/8`: use `kotlin-stdlib-jdk7/8` instead
- `kotlin-jslib` in the compiler distribution: use `kotlin-stdlib-js` instead

Deprecation cycle:

- 1.2.X: the artifacts were marked as deprecated, the compiler reported warning on usage of those artifacts
- >=1.3: the artifacts are discontinued

Annotations in stdlib

Issue: KT-21784

Component: kotlin-stdlib (JVM)

Incompatible change type: Binary

Short summary: Kotlin 1.3 removes annotations from the package `org.jetbrains.annotations` from stdlib and moves them to the separate artifacts shipped with the compiler: `annotations-13.0.jar` and `mutability-annotations-compat.jar`

Deprecation cycle:

- <1.3: annotations were shipped with the stdlib artifact
- >=1.3: annotations ship in separate artifacts

What's new in Kotlin 1.2

Released: 28 November 2017

Table of contents

- Multiplatform projects
- Other language features
- Standard library
- JVM backend
- JavaScript backend

For information about the Kotlin release cycle, see Kotlin release process.

Multiplatform projects (experimental)

Multiplatform projects are a new **experimental** feature in Kotlin 1.2, allowing you to reuse code between target platforms supported by Kotlin – JVM, JavaScript, and (in the future) Native. In a multiplatform project, you have three kinds of modules:

- A *common* module contains code that is not specific to any platform, as well as declarations without implementation of platform-dependent APIs.
- A *platform* module contains implementations of platform-dependent declarations in the common module for a specific platform, as well as other platform-dependent code.
- A regular module targets a specific platform and can either be a dependency of platform modules or depend on platform modules.

When you compile a multiplatform project for a specific platform, the code for both the common and platform-specific parts is generated.

A key feature of the multiplatform project support is the possibility to express dependencies of common code on platform-specific parts through *expected* and *actual* declarations. An *expected* declaration specifies an API (class, interface, annotation, top-level declaration etc.). An *actual* declaration is either a platform-dependent implementation of the API or a type alias referring to an existing implementation of the API in an external library. Here's an example:

In the common code:

```
// expected platform-specific API:
expect fun hello(world: String): String

fun greet() {
    // usage of the expected API:
    val greeting = hello("multiplatform world")
    println(greeting)
}

expect class URL(spec: String) {
    open fun getHost(): String
    open fun getPath(): String
}
```

In the JVM platform code:

```
actual fun hello(world: String): String =
    "Hello, $world, on the JVM platform!"

// using existing platform-specific implementation:
actual typealias URL = java.net.URL
```

See the multiplatform programming documentation for details and steps to build a multiplatform project.

Other language features

Array literals in annotations

Starting with Kotlin 1.2, array arguments for annotations can be passed with the new array literal syntax instead of the `arrayOf` function:

```
@CacheConfig(cacheNames = ["books", "default"])
public class BookRepositoryImpl {
    // ...
}
```

The array literal syntax is constrained to annotation arguments.

Lateinit top-level properties and local variables

The `lateinit` modifier can now be used on top-level properties and local variables. The latter can be used, for example, when a lambda passed as a constructor argument to one object refers to another object which has to be defined later:

```
class Node<T>(val value: T, val next: () -> Node<T>)

fun main(args: Array<String>) {
    // A cycle of three nodes:
    lateinit var third: Node<Int>

    val second = Node(2, next = { third })
    val first = Node(1, next = { second })

    third = Node(3, next = { first })

    val nodes = generateSequence(first) { it.next() }
    println("Values in the cycle: ${nodes.take(7).joinToString { it.value.toString() }}, ...")
}
```

Check whether a lateinit var is initialized

You can now check whether a lateinit var has been initialized using `isInitialized` on the property reference:

```
class Foo {
    lateinit var lateinitVar: String

    fun initializationLogic() {
        println("isInitialized before assignment: " + this::lateinitVar.isInitialized)
        lateinitVar = "value"
        println("isInitialized after assignment: " + this::lateinitVar.isInitialized)
    }
}

fun main(args: Array<String>) {
        Foo().initializationLogic()
}
```

Inline functions with default functional parameters

Inline functions are now allowed to have default values for their inlined functional parameters:

```
inline fun <E> Iterable<E>.strings(transform: (E) -> String = { it.toString() }) =
    map { transform(it) }

val defaultStrings = listOf(1, 2, 3).strings()
val customStrings = listOf(1, 2, 3).strings { "($it)" }

fun main(args: Array<String>) {
    println("defaultStrings = $defaultStrings")
    println("customStrings = $customStrings")
}
```

Information from explicit casts is used for type inference

The Kotlin compiler can now use information from type casts in type inference. If you're calling a generic method that returns a type parameter `T` and casting the return value to a specific type `Foo`, the compiler now understands that `T` for this call needs to be bound to the type `Foo`.

This is particularly important for Android developers, since the compiler can now correctly analyze generic `findViewById` calls in Android API level 26:

```
val button = findViewById(R.id.button) as Button
```

Smart cast improvements

When a variable is assigned from a safe call expression and checked for null, the smart cast is now applied to the safe call receiver as well:

```
fun countFirst(s: Any): Int {
    val firstChar = (s as? CharSequence)?.firstOrNull()
    if (firstChar ≠ null)
    return s.count { it == firstChar } // s: Any is smart cast to CharSequence

    val firstItem = (s as? Iterable<*>)?.firstOrNull()
    if (firstItem ≠ null)
    return s.count { it == firstItem } // s: Any is smart cast to Iterable<*>
    return -1
}

fun main(args: Array<String>) {
  val string = "abacaba"
  val countInString = countFirst(string)
  println("called on \"$string\": $countInString")

  val list = listOf(1, 2, 3, 1, 2)
  val countInList = countFirst(list)
  println("called on $list: $countInList")
}
```

Also, smart casts in a lambda are now allowed for local variables that are only modified before the lambda:

```
fun main(args: Array<String>) {
    val flag = args.size == 0
    var x: String? = null
    if (flag) x = "Yahoo!"

    run {
        if (x ≠ null) {
            println(x.length) // x is smart cast to String
        }
    }
}
```

Support for ::foo as a shorthand for this::foo

A bound callable reference to a member of `this` can now be written without explicit receiver, `::foo` instead of `this::foo`. This also makes callable references more convenient to use in lambdas where you refer to a member of the outer receiver.

Breaking change: sound smart casts after try blocks

Earlier, Kotlin used assignments made inside a `try` block for smart casts after the block, which could break type- and null-safety and lead to runtime failures. This release fixes this issue, making the smart casts more strict, but breaking some code that relied on such smart casts.

To switch to the old smart casts behavior, pass the fallback flag `-Xlegacy-smart-cast-after-try` as the compiler argument. It will become deprecated in Kotlin 1.3.

Deprecation: data classes overriding copy

When a data class derived from a type that already had the `copy` function with the same signature, the `copy` implementation generated for the data class used the defaults from the supertype, leading to counter-intuitive behavior, or failed at runtime if there were no default parameters in the supertype.

Inheritance that leads to a `copy` conflict has become deprecated with a warning in Kotlin 1.2 and will be an error in Kotlin 1.3.

Deprecation: nested types in enum entries

Inside enum entries, defining a nested type that is not an `inner class` has been deprecated due to issues in the initialization logic. This causes a warning in Kotlin 1.2 and will become an error in Kotlin 1.3.

Deprecation: single named argument for vararg

For consistency with array literals in annotations, passing a single item for a vararg parameter in the named form (`foo(items = i)`) has been deprecated. Please use the spread operator with the corresponding array factory functions:

```
foo(items = *arrayOf(1))
```

There is an optimization that removes redundant arrays creation in such cases, which prevents performance degradation. The single-argument form produces warnings in Kotlin 1.2 and is to be dropped in Kotlin 1.3.

Deprecation: inner classes of generic classes extending Throwable

Inner classes of generic types that inherit from `Throwable` could violate type-safety in a throw-catch scenario and thus have been deprecated, with a warning in Kotlin 1.2 and an error in Kotlin 1.3.

Deprecation: mutating backing field of a read-only property

Mutating the backing field of a read-only property by assigning `field = ...` in the custom getter has been deprecated, with a warning in Kotlin 1.2 and an error in Kotlin 1.3.

Standard library

Kotlin standard library artifacts and split packages

The Kotlin standard library is now fully compatible with the Java 9 module system, which forbids split packages (multiple jar files declaring classes in the same package). In order to support that, new artifacts `kotlin-stdlib-jdk7` and `kotlin-stdlib-jdk8` are introduced, which replace the old `kotlin-stdlib-jre7` and `kotlin-stdlib-jre8`.

The declarations in the new artifacts are visible under the same package names from the Kotlin point of view, but have different package names for Java. Therefore, switching to the new artifacts will not require any changes to your source code.

Another change made to ensure compatibility with the new module system is removing the deprecated declarations in the `kotlin.reflect` package from the `kotlin-reflect` library. If you were using them, you need to switch to using the declarations in the `kotlin.reflect.full` package, which is supported since Kotlin 1.1.

windowed, chunked, zipWithNext

New extensions for `Iterable<T>`, `Sequence<T>`, and `CharSequence` cover such use cases as buffering or batch processing (`chunked`), sliding window and computing sliding average (`windowed`), and processing pairs of subsequent items (`zipWithNext`):

```
fun main(args: Array<String>) {
    val items = (1..9).map { it * it }

    val chunkedIntoLists = items.chunked(4)
    val points3d = items.chunked(3) { (x, y, z) -> Triple(x, y, z) }
    val windowed = items.windowed(4)
    val slidingAverage = items.windowed(4) { it.average() }
    val pairwiseDifferences = items.zipWithNext { a, b -> b - a }

    println("items: $items\n")

    println("chunked into lists: $chunkedIntoLists")
    println("3D points: $points3d")
    println("windowed by 4: $windowed")
    println("sliding average by 4: $slidingAverage")
    println("pairwise differences: $pairwiseDifferences")
}
```

fill, replaceAll, shuffle/shuffled

A set of extension functions was added for manipulating lists: `fill`, `replaceAll` and `shuffle` for `MutableList`, and `shuffled` for read-only `List`:

```
fun main(args: Array<String>) {
    val items = (1..5).toMutableList()

    items.shuffle()
    println("Shuffled items: $items")

    items.replaceAll { it * 2 }
    println("Items doubled: $items")

    items.fill(5)
    println("Items filled with 5: $items")
}
```

Math operations in kotlin-stdlib

Satisfying the longstanding request, Kotlin 1.2 adds the `kotlin.math` API for math operations that is common for JVM and JS and contains the following:

- Constants: `PI` and `E`
- Trigonometric: `cos`, `sin`, `tan` and inverse of them: `acos`, `asin`, `atan`, `atan2`
- Hyperbolic: `cosh`, `sinh`, `tanh` and their inverse: `acosh`, `asinh`, `atanh`
- Exponentation: `pow` (an extension function), `sqrt`, `hypot`, `exp`, `expm1`
- Logarithms: `log`, `log2`, `log10`, `ln`, `ln1p`
- Rounding:
  - `ceil`, `floor`, `truncate`, `round` (half to even) functions
  - `roundToInt`, `roundToLong` (half to integer) extension functions
- Sign and absolute value:
  - `abs` and `sign` functions
  - `absoluteValue` and `sign` extension properties
  - `withSign` extension function
- `max` and `min` of two values
- Binary representation:
  - `ulp` extension property
  - `nextUp`, `nextDown`, `nextTowards` extension functions
  - `toBits`, `toRawBits`, `Double.fromBits` (these are in the `kotlin` package)

The same set of functions (but without constants) is also available for `Float` arguments.

Operators and conversions for BigInteger and BigDecimal

Kotlin 1.2 introduces a set of functions for operating with `BigInteger` and `BigDecimal` and creating them from other numeric types. These are:

- `toBigInteger` for `Int` and `Long`
- `toBigDecimal` for `Int`, `Long`, `Float`, `Double`, and `BigInteger`
- Arithmetic and bitwise operator functions:
  - Binary operators `+`, `-`, `*`, `/`, `%` and infix functions `and`, `or`, `xor`, `shl`, `shr`
  - Unary operators `-`, `++`, `--`, and a function `inv`

Floating point to bits conversions

New functions were added for converting `Double` and `Float` to and from their bit representations:

- `toBits` and `toRawBits` returning `Long` for `Double` and `Int` for `Float`
- `Double.fromBits` and `Float.fromBits` for creating floating point numbers from the bit representation

Regex is now serializable

The `kotlin.text.Regex` class has become `Serializable` and can now be used in serializable hierarchies.

Closeable.use calls Throwable.addSuppressed if available

The `Closeable.use` function calls `Throwable.addSuppressed` when an exception is thrown during closing the resource after some other exception.

To enable this behavior you need to have `kotlin-stdlib-jdk7` in your dependencies.

JVM backend

Constructor calls normalization

Ever since version 1.0, Kotlin supported expressions with complex control flow, such as try-catch expressions and inline function calls. Such code is valid according to the Java Virtual Machine specification. Unfortunately, some bytecode processing tools do not handle such code quite well when such expressions are present in the arguments of constructor calls.

To mitigate this problem for the users of such bytecode processing tools, we've added a command-line compiler option (`-Xnormalize-constructor-calls=MODE`) that tells the compiler to generate more Java-like bytecode for such constructs. Here `MODE` is one of:

- `disable` (default) – generate bytecode in the same way as in Kotlin 1.0 and 1.1.
- `enable` – generate Java-like bytecode for constructor calls. This can change the order in which the classes are loaded and initialized.
- `preserve-class-initialization` – generate Java-like bytecode for constructor calls, ensuring that the class initialization order is preserved. This can affect overall performance of your application; use it only if you have some complex state shared between multiple classes and updated on class initialization.

The "manual" workaround is to store the values of sub-expressions with control flow in variables, instead of evaluating them directly inside the call arguments. It's similar to `-Xnormalize-constructor-calls=enable`.

Java-default method calls

Before Kotlin 1.2, interface members overriding Java-default methods while targeting JVM 1.6 produced a warning on super calls: `Super calls to Java default methods are deprecated in JVM target 1.6. Recompile with '-jvm-target 1.8'`. In Kotlin 1.2, there's an **error** instead, thus requiring any such code to be compiled with JVM target 1.8.

Breaking change: consistent behavior of x.equals(null) for platform types

Calling `x.equals(null)` on a platform type that is mapped to a Java primitive (`Int!`, `Boolean!`, `Short`!, `Long!`, `Float!`, `Double!`, `Char!`) incorrectly returned `true` when `x` was null. Starting with Kotlin 1.2, calling `x.equals(...)` on a null value of a platform type **throws an NPE** (but `x == ...` does not).

To return to the pre-1.2 behavior, pass the flag `-Xno-exception-on-explicit-equals-for-boxed-null` to the compiler.

Breaking change: fix for platform null escaping through an inlined extension receiver

Inline extension functions that were called on a null value of a platform type did not check the receiver for null and would thus allow null to escape into the other code. Kotlin 1.2 forces this check at the call sites, throwing an exception if the receiver is null.

To switch to the old behavior, pass the fallback flag `-Xno-receiver-assertions` to the compiler.

JavaScript backend

TypedArrays support enabled by default

The JS typed arrays support that translates Kotlin primitive arrays, such as `IntArray`, `DoubleArray`, into JavaScript typed arrays, that was previously an opt-in feature, has been enabled by default.

Tools

Warnings as errors

The compiler now provides an option to treat all warnings as errors. Use `-Werror` on the command line, or the following Gradle snippet:

```
compileKotlin {
    kotlinOptions.allWarningsAsErrors = true
}
```

What's new in Kotlin 1.1

Released: 15 February 2016

Table of contents

- Coroutines
- Other language features
- Standard library
- JVM backend
- JavaScript backend

For information about the Kotlin release cycle, see Kotlin release process.

JavaScript

Starting with Kotlin 1.1, the JavaScript target is no longer considered experimental. All language features are supported, and there are many new tools for integration with the frontend development environment. See below for a more detailed list of changes.

Coroutines (experimental)

The key new feature in Kotlin 1.1 is *coroutines*, bringing the support of `async` / `await`, `yield`, and similar programming patterns. The key feature of Kotlin's design is that the implementation of coroutine execution is part of the libraries, not the language, so you aren't bound to any specific programming paradigm or concurrency library.

A coroutine is effectively a light-weight thread that can be suspended and resumed later. Coroutines are supported through *suspending functions*: a call to such a function can potentially suspend a coroutine, and to start a new coroutine we usually use an anonymous suspending functions (i.e. suspending lambdas).

Let's look at `async` / `await` which is implemented in an external library, kotlinx.coroutines:

```
// runs the code in the background thread pool
fun asyncOverlay() = async(CommonPool) {
    // start two async operations
    val original = asyncLoadImage("original")
    val overlay = asyncLoadImage("overlay")
    // and then apply overlay to both results
    applyOverlay(original.await(), overlay.await())
}

// launches new coroutine in UI context
launch(UI) {
    // wait for async overlay to complete
    val image = asyncOverlay().await()
    // and then show it in UI
    showImage(image)
}
```

Here, `async { ... }` starts a coroutine and, when we use `await()`, the execution of the coroutine is suspended while the operation being awaited is executed, and is resumed (possibly on a different thread) when the operation being awaited completes.

The standard library uses coroutines to support *lazily generated sequences* with `yield` and `yieldAll` functions. In such a sequence, the block of code that returns sequence elements is suspended after each element has been retrieved, and resumed when the next element is requested. Here's an example:

```
import kotlin.coroutines.experimental.*

fun main(args: Array<String>) {
    val seq = buildSequence {
      for (i in 1..5) {
          // yield a square of i
          yield(i * i)
      }
      // yield a range
      yieldAll(26..28)
    }

    // print the sequence
    println(seq.toList())
}
```

Run the code above to see the result. Feel free to edit it and run again!

For more information, please refer to the coroutines documentation and tutorial.

Note that coroutines are currently considered an **experimental feature**, meaning that the Kotlin team is not committing to supporting the backwards compatibility of this feature after the final 1.1 release.

Other language features

Type aliases

A type alias allows you to define an alternative name for an existing type. This is most useful for generic types such as collections, as well as for function types. Here is an example:

```
typealias OscarWinners = Map<String, String>

fun countLaLaLand(oscarWinners: OscarWinners) =
        oscarWinners.count { it.value.contains("La La Land") }

// Note that the type names (initial and the type alias) are interchangeable:
fun checkLaLaLandIsTheBestMovie(oscarWinners: Map<String, String>) =
        oscarWinners["Best picture"] == "La La Land"

fun oscarWinners(): OscarWinners {
    return mapOf(
            "Best song" to "City of Stars (La La Land)",
            "Best actress" to "Emma Stone (La La Land)",
            "Best picture" to "Moonlight" /* ... */)
}

fun main(args: Array<String>) {
    val oscarWinners = oscarWinners()

    val laLaLandAwards = countLaLaLand(oscarWinners)
    println("LaLaLandAwards = $laLaLandAwards (in our small example), but actually it's 6.")

    val laLaLandIsTheBestMovie = checkLaLaLandIsTheBestMovie(oscarWinners)
    println("LaLaLandIsTheBestMovie = $laLaLandIsTheBestMovie")
}
```

See the type aliases documentation and KEEP for more details.

Bound callable references

You can now use the `::` operator to get a member reference pointing to a method or property of a specific object instance. Previously this could only be expressed with a lambda. Here's an example:

```
val numberRegex = "\\d+".toRegex()
val numbers = listOf("abc", "123", "456").filter(numberRegex::matches)

fun main(args: Array<String>) {
    println("Result is $numbers")
}
```

Read the documentation and KEEP for more details.

Sealed and data classes

Kotlin 1.1 removes some of the restrictions on sealed and data classes that were present in Kotlin 1.0. Now you can define subclasses of a top-level sealed class on the top level in the same file, and not just as nested classes of the sealed class. Data classes can now extend other classes. This can be used to define a hierarchy of expression classes nicely and cleanly:

```
sealed class Expr

data class Const(val number: Double) : Expr()
data class Sum(val e1: Expr, val e2: Expr) : Expr()
object NotANumber : Expr()

fun eval(expr: Expr): Double = when (expr) {
    is Const -> expr.number
    is Sum -> eval(expr.e1) + eval(expr.e2)
    NotANumber -> Double.NaN
}
val e = eval(Sum(Const(1.0), Const(2.0)))

fun main(args: Array<String>) {
    println("e is $e") // 3.0
}
```

Read the sealed classes documentation or KEEPs for sealed class and data class for more detail.

Destructuring in lambdas

You can now use the destructuring declaration syntax to unpack the arguments passed to a lambda. Here's an example:

```
fun main(args: Array<String>) {
    val map = mapOf(1 to "one", 2 to "two")
    // before
    println(map.mapValues { entry ->
      val (key, value) = entry
      "$key -> $value!"
    })
    // now
    println(map.mapValues { (key, value) -> "$key -> $value!" })
}
```

Read the destructuring declarations documentation and KEEP for more details.

Underscores for unused parameters

For a lambda with multiple parameters, you can use the `_` character to replace the names of the parameters you don't use:

```
fun main(args: Array<String>) {
    val map = mapOf(1 to "one", 2 to "two")

    map.forEach { _, value -> println("$value!") }
}
```

This also works in destructuring declarations:

```
data class Result(val value: Any, val status: String)

fun getResult() = Result(42, "ok").also { println("getResult() returns $it") }

fun main(args: Array<String>) {
    val (_, status) = getResult()
    println("status is '$status'")
}
```

Read the KEEP for more details.

Underscores in numeric literals

Just as in Java 8, Kotlin now allows to use underscores in numeric literals to separate groups of digits:

```
val oneMillion = 1_000_000
val hexBytes = 0xFF_EC_DE_5E
val bytes = 0b11010010_01101001_10010100_10010010

fun main(args: Array<String>) {
    println(oneMillion)
    println(hexBytes.toString(16))
    println(bytes.toString(2))
}
```

Read the KEEP for more details.

Shorter syntax for properties

For properties with the getter defined as an expression body, the property type can now be omitted:

```
    data class Person(val name: String, val age: Int) {
    val isAdult get() = age ⩾ 20 // Property type inferred to be 'Boolean'
}
fun main(args: Array<String>) {
    val akari = Person("Akari", 26)
    println("$akari.isAdult = ${akari.isAdult}")
}
```

Inline property accessors

You can now mark property accessors with the `inline` modifier if the properties don't have a backing field. Such accessors are compiled in the same way as inline functions.

```
public val <T> List<T>.lastIndex: Int
    inline get() = this.size - 1

fun main(args: Array<String>) {
    val list = listOf('a', 'b')
    // the getter will be inlined
    println("Last index of $list is ${list.lastIndex}")
}
```

You can also mark the entire property as `inline` - then the modifier is applied to both accessors.

Read the inline functions documentation and KEEP for more details.

Local delegated properties

You can now use the delegated property syntax with local variables. One possible use is defining a lazily evaluated local variable:

```
import java.util.Random

fun needAnswer() = Random().nextBoolean()

fun main(args: Array<String>) {
    val answer by lazy {
        println("Calculating the answer...")
        42
    }
    if (needAnswer()) {                    // returns the random value
        println("The answer is $answer.")   // answer is calculated at this point
    }
    else {
        println("Sometimes no answer is the answer...")
    }
}
```

Read the KEEP for more details.

Interception of delegated property binding

For delegated properties, it is now possible to intercept delegate to property binding using the `provideDelegate` operator. For example, if we want to check the property name before binding, we can write something like this:

```
class ResourceLoader<T>(id: ResourceID<T>) {
    operator fun provideDelegate(thisRef: MyUI, prop: KProperty<*>): ReadOnlyProperty<MyUI, T> {
        checkProperty(thisRef, prop.name)
        ... // property creation
    }

    private fun checkProperty(thisRef: MyUI, name: String) { ... }
}

fun <T> bindResource(id: ResourceID<T>): ResourceLoader<T> { ... }

class MyUI {
    val image by bindResource(ResourceID.image_id)
    val text by bindResource(ResourceID.text_id)
}
```

The `provideDelegate` method will be called for each property during the creation of a `MyUI` instance, and it can perform the necessary validation right away.

Read the delegated properties documentation for more details.

Generic enum value access

It is now possible to enumerate the values of an enum class in a generic way.

```
enum class RGB { RED, GREEN, BLUE }

inline fun <reified T : Enum<T>> printAllValues() {
    print(enumValues<T>().joinToString { it.name })
}

fun main(args: Array<String>) {
    printAllValues<RGB>() // prints RED, GREEN, BLUE
}
```

Scope control for implicit receivers in DSLs

The `@DslMarker` annotation allows to restrict the use of receivers from outer scopes in a DSL context. Consider the canonical HTML builder example:

```
table {
    tr {
        td { + "Text" }
    }
}
```

In Kotlin 1.0, code in the lambda passed to `td` has access to three implicit receivers: the one passed to `table`, to `tr` and to `td`. This allows you to call methods that make no sense in the context - for example to call `tr` inside `td` and thus to put a `<tr>` tag in a `<td>`.

In Kotlin 1.1, you can restrict that, so that only methods defined on the implicit receiver of `td` will be available inside the lambda passed to `td`. You do that by defining your annotation marked with the `@DslMarker` meta-annotation and applying it to the base class of the tag classes.

Read the type safe builders documentation and KEEP for more details.

rem operator

The `mod` operator is now deprecated, and `rem` is used instead. See this issue for motivation.

Standard library

String to number conversions

There is a bunch of new extensions on the String class to convert it to a number without throwing an exception on invalid number: `String.toIntOrNull(): Int?`, `String.toDoubleOrNull(): Double?` etc.

```
val port = System.getenv("PORT")?.toIntOrNull() ?: 80
```

Also integer conversion functions, like `Int.toString()`, `String.toInt()`, `String.toIntOrNull()`, each got an overload with `radix` parameter, which allows to specify the base of conversion (2 to 36).

onEach()

`onEach` is a small, but useful extension function for collections and sequences, which allows to perform some action, possibly with side-effects, on each element of the collection/sequence in a chain of operations. On iterables it behaves like `forEach` but also returns the iterable instance further. And on sequences it returns a wrapping sequence, which applies the given action lazily as the elements are being iterated.

```
inputDir.walk()
        .filter { it.isFile && it.name.endsWith(".txt") }
        .onEach { println("Moving $it to $outputDir") }
        .forEach { moveFile(it, File(outputDir, it.toRelativeString(inputDir))) }
```

also(), takeIf(), and takeUnless()

These are three general-purpose extension functions applicable to any receiver.

`also` is like `apply` : it takes the receiver, does some action on it, and returns that receiver. The difference is that in the block inside `apply` the receiver is available as `this` , while in the block inside `also` it's available as `it` (and you can give it another name if you want). This comes handy when you do not want to shadow `this` from the outer scope:

```
class Block {
    lateinit var content: String
}

fun Block.copy() = Block().also {
    it.content = this.content
}

// using 'apply' instead
fun Block.copy1() = Block().apply {
    this.content = this@copy1.content
}

fun main(args: Array<String>) {
    val block = Block().apply { content = "content" }
    val copy = block.copy()
    println("Testing the content was copied:")
    println(block.content == copy.content)
}
```

`takeIf` is like `filter` for a single value. It checks whether the receiver meets the predicate, and returns the receiver, if it does or `null` if it doesn't. Combined with an elvis operator (?:) and early returns it allows writing constructs like:

```
val outDirFile = File(outputDir.path).takeIf { it.exists() } ?: return false
// do something with existing outDirFile
```

```
fun main(args: Array<String>) {
    val input = "Kotlin"
    val keyword = "in"

    val index = input.indexOf(keyword).takeIf { it ≥ 0 } ?: error("keyword not found")
    // do something with index of keyword in input string, given that it's found

    println("'$keyword' was found in '$input'")
    println(input)
    println(" ".repeat(index) + "^")
}
```

`takeUnless` is the same as `takeIf` , but it takes the inverted predicate. It returns the receiver when it *doesn't* meet the predicate and `null` otherwise. So one of the examples above could be rewritten with `takeUnless` as following:

```
val index = input.indexOf(keyword).takeUnless { it < 0 } ?: error("keyword not found")
```

It is also convenient to use when you have a callable reference instead of the lambda:

```
private fun testTakeUnless(string: String) {
    val result = string.takeUnless(String::isEmpty)

    println("string = \"$string\"; result = \"$result\"")
}

fun main(args: Array<String>) {
    testTakeUnless("")
    testTakeUnless("abc")
}
```

groupingBy()

This API can be used to group a collection by key and fold each group simultaneously. For example, it can be used to count the number of words starting with each letter:

```
fun main(args: Array<String>) {
    val words = "one two three four five six seven eight nine ten".split(' ')
    val frequencies = words.groupingBy { it.first() }.eachCount()
    println("Counting first letters: $frequencies.")

    // The alternative way that uses 'groupBy' and 'mapValues' creates an intermediate map,
    // while 'groupingBy' way counts on the fly.
    val groupBy = words.groupBy { it.first() }.mapValues { (_, list) -> list.size }
    println("Comparing the result with using 'groupBy': ${groupBy == frequencies}.")
}
```

Map.toMap() and Map.toMutableMap()

These functions can be used for easy copying of maps:

```
class ImmutablePropertyBag(map: Map<String, Any>) {
    private val mapCopy = map.toMap()
}
```

Map.minus(key)

The operator `plus` provides a way to add key-value pair(s) to a read-only map producing a new map, however there was not a simple way to do the opposite: to remove a key from the map you have to resort to less straightforward ways to like `Map.filter()` or `Map.filterKeys()`. Now the operator `minus` fills this gap. There are 4 overloads available: for removing a single key, a collection of keys, a sequence of keys and an array of keys.

```
fun main(args: Array<String>) {
    val map = mapOf("key" to 42)
    val emptyMap = map - "key"

    println("map: $map")
    println("emptyMap: $emptyMap")
}
```

minOf() and maxOf()

These functions can be used to find the lowest and greatest of two or three given values, where values are primitive numbers or `Comparable` objects. There is also an overload of each function that take an additional `Comparator` instance if you want to compare objects that are not comparable themselves.

```
fun main(args: Array<String>) {
    val list1 = listOf("a", "b")
    val list2 = listOf("x", "y", "z")
    val minSize = minOf(list1.size, list2.size)
    val longestList = maxOf(list1, list2, compareBy { it.size })

    println("minSize = $minSize")
    println("longestList = $longestList")
}
```

Array-like List instantiation functions

Similar to the `Array` constructor, there are now functions that create `List` and `MutableList` instances and initialize each element by calling a lambda:

```
fun main(args: Array<String>) {
    val squares = List(10) { index -> index * index }
    val mutable = MutableList(10) { 0 }

    println("squares: $squares")
    println("mutable: $mutable")
}
```

Map.getValue()

This extension on `Map` returns an existing value corresponding to the given key or throws an exception, mentioning which key was not found. If the map was produced with `withDefault`, this function will return the default value instead of throwing an exception.

```
fun main(args: Array<String>) {
//sampleStart
    val map = mapOf("key" to 42)
    // returns non-nullable Int value 42
    val value: Int = map.getValue("key")

    val mapWithDefault = map.withDefault { k -> k.length }
    // returns 4
    val value2 = mapWithDefault.getValue("key2")

    // map.getValue("anotherKey") // ← this will throw NoSuchElementException

    println("value is $value")
    println("value2 is $value2")
}
```

Abstract collections

These abstract classes can be used as base classes when implementing Kotlin collection classes. For implementing read-only collections there are `AbstractCollection`, `AbstractList`, `AbstractSet` and `AbstractMap`, and for mutable collections there are `AbstractMutableCollection`, `AbstractMutableList`

, `AbstractMutableSet` and `AbstractMutableMap`. On JVM, these abstract mutable collections inherit most of their functionality from JDK's abstract collections.

Array manipulation functions

The standard library now provides a set of functions for element-by-element operations on arrays: comparison (`contentEquals` and `contentDeepEquals`), hash code calculation (`contentHashCode` and `contentDeepHashCode`), and conversion to a string (`contentToString` and `contentDeepToString`). They're supported both for the JVM (where they act as aliases for the corresponding functions in `java.util.Arrays`) and for JS (where the implementation is provided in the Kotlin standard library).

```
fun main(args: Array<String>) {
    val array = arrayOf("a", "b", "c")
    println(array.toString())  // JVM implementation: type-and-hash gibberish
    println(array.contentToString())  // nicely formatted as list
}
```

JVM Backend

Java 8 bytecode support

Kotlin has now the option of generating Java 8 bytecode (`-jvm-target 1.8` command line option or the corresponding options in Maven/Gradle). For now this doesn't change the semantics of the bytecode (in particular, default methods in interfaces and lambdas are generated exactly as in Kotlin 1.0), but we plan to make further use of this later.

Java 8 standard library support

There are now separate versions of the standard library supporting the new JDK APIs added in Java 7 and 8. If you need access to the new APIs, use `kotlin-stdlib-jre7` and `kotlin-stdlib-jre8` maven artifacts instead of the standard `kotlin-stdlib` . These artifacts are tiny extensions on top of `kotlin-stdlib` and they bring it to your project as a transitive dependency.

Parameter names in the bytecode

Kotlin now supports storing parameter names in the bytecode. This can be enabled using the `-java-parameters` command line option.

Constant inlining

The compiler now inlines values of `const val` properties into the locations where they are used.

Mutable closure variables

The box classes used for capturing mutable closure variables in lambdas no longer have volatile fields. This change improves performance, but can lead to new race conditions in some rare usage scenarios. If you're affected by this, you need to provide your own synchronization for accessing the variables.

javax.script support

Kotlin now integrates with the javax.script API (JSR-223). The API allows to evaluate snippets of code at runtime:

```
val engine = ScriptEngineManager().getEngineByExtension("kts")!!
engine.eval("val x = 3")
println(engine.eval("x + 2"))  // Prints out 5
```

See here for a larger example project using the API.

kotlin.reflect.full

To prepare for Java 9 support, the extension functions and properties in the `kotlin-reflect.jar` library have been moved to the package `kotlin.reflect.full`. The names in the old package (`kotlin.reflect`) are deprecated and will be removed in Kotlin 1.2. Note that the core reflection interfaces (such as `KClass`) are part of the Kotlin standard library, not `kotlin-reflect`, and are not affected by the move.

JavaScript backend

Unified standard library

A much larger part of the Kotlin standard library can now be used from code compiled to JavaScript. In particular, key classes such as collections (`ArrayList`, `HashMap` etc.), exceptions (`IllegalArgumentException` etc.) and a few others (`StringBuilder`, `Comparator`) are now defined under the `kotlin` package. On the JVM, the names are type aliases for the corresponding JDK classes, and on the JS, the classes are implemented in the Kotlin standard library.

Better code generation

JavaScript backend now generates more statically checkable code, which is friendlier to JS code processing tools, like minifiers, optimisers, linters, etc.

The external modifier

If you need to access a class implemented in JavaScript from Kotlin in a typesafe way, you can write a Kotlin declaration using the `external` modifier. (In Kotlin 1.0, the `@native` annotation was used instead.) Unlike the JVM target, the JS one permits to use external modifier with classes and properties. For example, here's how you can declare the DOM `Node` class:

```
external class Node {
    val firstChild: Node

    fun appendChild(child: Node): Node

    fun removeChild(child: Node): Node

    // etc
}
```

Improved import handling

You can now describe declarations which should be imported from JavaScript modules more precisely. If you add the `@JsModule("<module-name>")` annotation on an external declaration it will be properly imported to a module system (either CommonJS or AMD) during the compilation. For example, with CommonJS the declaration will be imported via `require(...)` function. Additionally, if you want to import a declaration either as a module or as a global JavaScript object, you can use the `@JsNonModule` annotation.

For example, here's how you can import JQuery into a Kotlin module:

```
external interface JQuery {
    fun toggle(duration: Int = definedExternally): JQuery
    fun click(handler: (Event) -> Unit): JQuery
}

@JsModule("jquery")
@JsNonModule
@JsName("$")
external fun jquery(selector: String): JQuery
```

In this case, JQuery will be imported as a module named `jquery`. Alternatively, it can be used as a $-object, depending on what module system Kotlin compiler is configured to use.

You can use these declarations in your application like this:

```
fun main(args: Array<String>) {
    jquery(".toggle-button").click {
        jquery(".toggle-panel").toggle(300)
    }
}
```

Participate in the Kotlin Early Access Preview

You can participate in the Kotlin Early Access Preview (EAP) to try out the latest Kotlin features before they are released.

Before every language (*2.x.0*) and tooling (*2.x.20*) release, we ship Early Access Preview (EAP) builds for you to test in real projects and share early feedback. Kotlin EAP builds typically include the following stages:

EAP build	Description
Beta1	Introduces the first set of upcoming features, improvements, and other significant changes. Gives you an early opportunity to evaluate new functionality and share feedback.
Beta2	Usually adds more features and refinements based on the feedback we've received. Is feature-complete and continues the preview of the upcoming release, further maturing previously introduced features.
RC	The first release candidate. Focuses on stabilizing the changes delivered in Beta1 and Beta2, as well as fixing regressions found during testing.

EAP build	Description
RC2	Includes important fixes to finalize the release and confirm readiness.

We'd appreciate it if you report any bugs you find to our issue tracker, YouTrack. In most cases, we can fix them before the final release, so you won't need to wait for the next Kotlin release to see your issues resolved.

By participating in the Early Access Preview and reporting bugs, you contribute to Kotlin and help us make it better for everyone in the growing Kotlin community.

If you have any questions or want to join the discussion, you're welcome to join the #eap channel in Kotlin Slack. In this channel, you can also get notifications about new EAP builds.

Configure your project for the Kotlin EAP version

> By participating in the EAP, you expressly acknowledge that the EAP version may not be reliable, may not work as intended, and may contain errors.
>
> We don't guarantee compatibility between EAP and final versions of the same release.

How the EAP can help you be more productive with Kotlin

- **Prepare for the Stable release**. If you work on a complex multimodule project, participating in the EAP may streamline your experience when you adopt the Stable release version. The sooner you update to the Stable version, the sooner you can take advantage of its performance improvements and new language features.

  The migration of huge and complex projects might take a while, not only because of their size, but also because some specific use cases may not have been covered by the Kotlin team yet. By participating in the EAP and continuously testing new versions of Kotlin, you can provide us with early feedback about your specific use cases. This will help us address as many issues as possible and ensure you can safely update to the Stable version when it's released. Check out how Slack benefits from testing Android, Kotlin, and Gradle pre-release versions.

- **Keep your library up-to-date**. If you're a library author, updating to the new Kotlin version is extremely important. Using older versions could block your users from updating Kotlin in their projects. Working with EAP versions allows you to support the latest Kotlin versions in your library almost immediately with the Stable release, which makes your users happier and your library more popular.

- **Share the experience**. If you're a Kotlin enthusiast and enjoy contributing to the Kotlin ecosystem by creating educational content, trying new features in the Kotlin EAP allows you to be among the first to share the experience of using the new cool features with the community.

Build details

No preview versions are currently available.

Configure your build for EAP

To configure your build to use the EAP version of Kotlin, you need to:

-

Specify the EAP version of Kotlin. Available EAP versions are listed here.

- Change the versions of dependencies to EAP ones. The EAP version of Kotlin may not work with the libraries of the previously released version.

The following procedures describe how to configure your build in Gradle and Maven:

- Configure in Gradle
- Configure in Maven

Configure in Gradle

This section describes how you can:

- Adjust the Kotlin version
- Adjust versions in dependencies

Adjust the Kotlin version

In the `plugins` block within `build.gradle(.kts)`, change the `KOTLIN-EAP-VERSION` to the actual EAP version, such as `2.4.20-RC3`. Available EAP versions are listed here.

Alternatively, you can specify the EAP version in the `pluginManagement` block in `settings.gradle(.kts)` – see Gradle documentation for details.

Here is an example for the Multiplatform project.

Kotlin

```
plugins {
    java
    kotlin("multiplatform") version "KOTLIN-EAP-VERSION"
}

repositories {
    mavenCentral()
}
```

Groovy

```
plugins {
    id 'java'
    id 'org.jetbrains.kotlin.multiplatform' version 'KOTLIN-EAP-VERSION'
}

repositories {
    mavenCentral()
}
```

Adjust versions in dependencies

If you use kotlinx libraries in your project, your versions of the libraries may not be compatible with the EAP version of Kotlin.

To resolve this issue, you need to specify the version of a compatible library in dependencies. For a list of compatible libraries, see EAP build details.

> In most cases we create libraries only for the first EAP version of a specific release and these libraries work with the subsequent EAP versions for this release.
>
> If there are incompatible changes in next EAP versions, we release a new version of the library.

Here is an example.

For the **kotlinx.coroutines** library, add the version number – `1.11.0` – that is compatible with `2.4.20-RC3`.

Kotlin

```
dependencies {
    implementation("org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0")
}
```

Groovy

```
dependencies {
    implementation "org.jetbrains.kotlinx:kotlinx-coroutines-core:1.11.0"
}
```

Configure in Maven

In the sample Maven project definition, replace `KOTLIN-EAP-VERSION` with the actual version, such as `2.4.20-RC3`. Available EAP versions are listed here.

```
<project ...>
    <properties>
        <kotlin.version>KOTLIN-EAP-VERSION</kotlin.version>
    </properties>

    <repositories>
        <repository>
           <id>mavenCentral</id>
           <url>https://repo1.maven.org/maven2/</url>
        </repository>
    </repositories>

    <pluginRepositories>
       <pluginRepository>
          <id>mavenCentral</id>
          <url>https://repo1.maven.org/maven2/</url>
       </pluginRepository>
    </pluginRepositories>

    <dependencies>
        <dependency>
            <groupId>org.jetbrains.kotlin</groupId>
            <artifactId>kotlin-stdlib</artifactId>
            <version>${kotlin.version}</version>
        </dependency>
    </dependencies>

    <build>
        <plugins>
            <plugin>
                <groupId>org.jetbrains.kotlin</groupId>
                <artifactId>kotlin-maven-plugin</artifactId>
                <version>${kotlin.version}</version>
                ...
            </plugin>
        </plugins>
    </build>
</project>
```

If you run into any problems

- Report an issue to our issue tracker, YouTrack.
- Find help in the #eap channel in Kotlin Slack (get an invite).
- Roll back to the latest stable version: change it in your build script file.

Learning materials overview

You can use the following materials and resources for learning Kotlin:

- Basic syntax – get a quick overview of the Kotlin syntax.
- Kotlin tour – learn the fundamentals of the Kotlin programming language.
- Idioms – learn how to write idiomatic Kotlin code for popular cases.
    - Java to Kotlin migration guide: Strings – learn how to perform typical tasks with strings in Java and Kotlin.

- Java to Kotlin migration guide: Collections — learn how to perform typical tasks with collections in Java and Kotlin.
- Java to Kotlin migration guide: Nullability — learn how to handle nullability in Java and Kotlin.

- Kotlin Koans – complete exercises to learn the Kotlin syntax. Each exercise is created as a failing unit test and your job is to make it pass. Recommended for developers with Java experience.
- Kotlin Core track by JetBrains Academy – learn all the Kotlin essentials while creating working applications step by step.
- Kotlin books – find books we've reviewed and recommend for learning Kotlin.
- Kotlin tips – watch short videos where the Kotlin team shows you how to use Kotlin in a more efficient and idiomatic way, so you can have more fun when writing code.
- Advent of Code puzzles – learn idiomatic Kotlin and test your language skills by completing short and fun tasks.
- Kotlin hands-on tutorials – complete long-form tutorials to fully grasp a technology. These tutorials guide you through a self-contained project related to a specific topic.
- Kotlin for Java Developers – learn the similarities and differences between Java and Kotlin in this course on Coursera.
- Kotlin documentation in PDF format – read our documentation offline.

Kotlin hands-on

A series of hands-on tutorials where you can create applications with Kotlin using a variety of different technologies and targeting multiple platforms. The exercises are divided into a series of steps, walking you through each section.

Creating a web app with Spring Boot and Kotlin

Build a simple application with database functionality using Spring Boot and Kotlin, and learn about the benefits of using Kotlin for backend development from a syntax perspective.

Start

Building web applications with React and Kotlin/JS

Create a React Application using Kotlin/JS, and see how you can leverage Kotlin's type system, library ecosystem, and interoperability features.

Start

Building web applications with Spring Boot and Kotlin

Build a simple blog application by combining the power of Spring Boot and Kotlin.

Start

Creating HTTP APIs with Ktor

Create a backend API for your application that responds to HTTP requests.

Start

Creating a WebSocket chat with Ktor

Create a simple Chat application using Ktor including both a JVM server and a JVM client.

Start

Creating an interactive website with Ktor

Learn how to serve files, use templating engines such as Freemarker and the kotlinx.html DSL, and work with form input from Ktor.

Start

Introduction to Kotlin coroutines and channels

Learn about coroutines in Kotlin and how you can communicate between them using channels.

Start

Introduction to Kotlin/Native

Create a simple HTTP client that can run natively on multiple platforms using Kotlin/Native and libcurl.

Start

Kotlin Multiplatform: networking and data storage

Learn how to create a mobile application for Android and iOS using Kotlin Multiplatform with Ktor and SQLDelight.

Start

Targeting iOS and Android with Kotlin Multiplatform

Learn how to create a mobile application that can target both iOS and Android using Kotlin Multiplatform.

Start

Kotlin tips

Kotlin Tips is a series of short videos where members of the Kotlin team show how to use Kotlin in a more efficient and idiomatic way to have more fun when writing code.

Subscribe to our YouTube channel to not miss new Kotlin Tips videos.

null + null in Kotlin

What happens when you add `null + null` in Kotlin, and what does it return? Sebastian Aigner addresses this mystery in our latest quick tip. Along the way, he also shows why there's no reason to be scared of nullables:

Watch video online.

Deduplicating collection items

Got a Kotlin collection that contains duplicates? Need a collection with only unique items? Let Sebastian Aigner show you how to remove duplicates from your lists, or turn them into sets in this Kotlin tip:

Watch video online.

The suspend and inline mystery

How come functions like `repeat()`, `map()` and `filter()` accept suspending functions in their lambdas, even though their signatures aren't coroutines-aware? In this episode of Kotlin Tips, Sebastian Aigner solves the riddle: it has something to do with the inline modifier:

Watch video online.

Unshadowing declarations with their fully qualified name

Shadowing means having two declarations in a scope have the same name. So, how do you pick? In this episode of Kotlin Tips, Sebastian Aigner shows you a simple Kotlin trick to call exactly the function that you need, using the power of fully qualified names:

Watch video online.

Return and throw with the Elvis operator

Elvis has entered the building once more! Sebastian Aigner explains why the operator is named after the famous singer, and how you can use `?:` in Kotlin to return or throw. The magic behind the scenes? The Nothing type.

Watch video online.

Destructuring declarations

With destructuring declarations in Kotlin, you can create multiple variables from a single object, all at once. In this video, Sebastian Aigner shows you a selection of things that can be destructured – pairs, lists, maps, and more. And what about your own objects? Kotlin's component functions provide an answer for those as well:

Watch video online.

Operator functions with nullable values

In Kotlin, you can override operators like addition and subtraction for your classes and supply your own logic. But what if you want to allow null values, both on their left and right sides? In this video, Sebastian Aigner answers this question:

Watch video online.

Timing code

Watch Sebastian Aigner give a quick overview of the `measureTimedValue()` function, and learn how you can time your code:

Watch video online.

Improving loops

In this video, Sebastian Aigner will demonstrate how to improve loops to make your code more readable, understandable, and concise:

Watch video online.

Strings

In this episode, Kate Petrova shows three tips to help you work with Strings in Kotlin:

Watch video online.

Doing more with the Elvis operator

In this video, Sebastian Aigner will show how to add more logic to the Elvis operator, such as logging to the right part of the operator:

Watch video online.

Kotlin collections

In this episode, Kate Petrova shows three tips to help you work with Kotlin Collections:

Watch video online.

What's next?

- Learn how to write idiomatic Kotlin code for popular cases

Kotlin Koans

Kotlin Koans are a series of exercises designed primarily for Java developers to help you become familiar with the Kotlin syntax. Each exercise is created as a failing unit test, and your job is to make it pass.

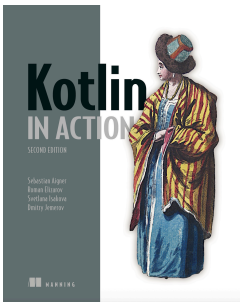
> You can check out the task content in our GitHub repository.

You can complete the Kotlin Koans tasks in one of the following ways:

- You can play with Koans online.

- You can perform the tasks right inside IntelliJ IDEA or Android Studio by installing the JetBrains Academy plugin and choosing the Kotlin Koans course.

Whatever way you choose to solve koans, you can see the solution for each task:



- In the online version, click **Show answer**.
- For the JetBrains Academy plugin, try to complete the task first and then choose **Peek solution** if your answer is incorrect.

We recommend you check the solution after implementing the task to compare your answer with the proposed one. Make sure you don't cheat!

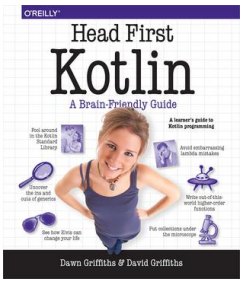
Kotlin books

More and more authors write books for learning Kotlin in different languages. We are very thankful to all of them and appreciate all their efforts in helping us increase a number of professional Kotlin developers.

Here are just a few books we've reviewed and recommend you for learning Kotlin. You can find more books on our community website.

Kotlin in Action

Kotlin in Action teaches you to use the Kotlin language for production-quality applications. Written for developers familiar with Java or other object-oriented languages, this example-rich book goes further than most language books. The second edition is enriched with an extensive section on the Kotlin coroutines library.

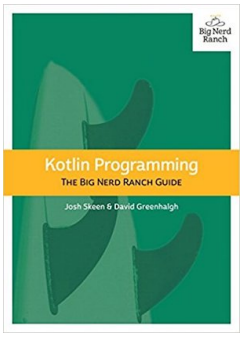


The book is written by Sebastian Aigner, Roman Elizarov, Svetlana Isakova, and Dmitry Jemerov, who are all either current or former members of the Kotlin team.

Atomic Kotlin

Atomic Kotlin is for both beginning and experienced programmers!

From Bruce Eckel, author of the multi-award-winning Thinking in C++ and Thinking in Java, and Svetlana Isakova, Kotlin Developer Advocate at JetBrains, comes a book that breaks the language concepts into small, easy-to-digest "atoms", along with a free course consisting of exercises supported by hints and solutions directly inside IntelliJ IDEA!



Head First Kotlin

Head First Kotlin is a complete introduction to coding in Kotlin. This hands-on book helps you learn the Kotlin language with a unique method that goes beyond syntax and how-to manuals and teaches you how to think like a great Kotlin developer.

You'll learn everything from language fundamentals to collections, generics, lambdas, and higher-order functions. Along the way, you'll get to play with both object-oriented and functional programming.

If you want to really understand Kotlin, this is the book for you.

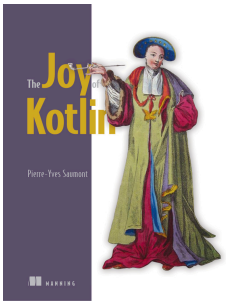
Kotlin Programming: The Big Nerd Ranch Guide

Kotlin Programming: The Big Nerd Ranch Guide

In this book you will learn to work effectively with the Kotlin language through carefully considered examples designed to teach you Kotlin's elegant style and features.

Starting from first principles, you will work your way to advanced usage of Kotlin, empowering you to create programs that are more reliable with less code.

Programming Kotlin



Programming Kotlin is written by Venkat Subramaniam.

Programmers don't just use Kotlin, they love it. Even Google has adopted it as a first-class language for Android development.

With Kotlin, you can intermix imperative, functional, and object-oriented styles of programming and benefit from the approach that's most suitable for the problem at hand.

Learn to use the many features of this highly concise, fluent, elegant, and expressive statically typed language with easy-to-understand examples.

Learn to write maintainable, high-performing JVM and Android applications, create DSLs, program asynchronously, and much more.

The Joy of Kotlin

The Joy of Kotlin teaches you the right way to code in Kotlin.

In this insight-rich book, you'll master the Kotlin language while exploring coding techniques that will make you a better developer no matter what language you use. Kotlin natively supports a functional style of programming, so seasoned author Pierre-Yves Saumont begins by reviewing the FP principles of immutability, referential transparency, and the separation between functions and effects.

Then, you'll move deeper into using Kotlin in the real world, as you learn to handle errors and data properly, encapsulate shared state mutations, and work with laziness.

This book will change the way you code — and give you back some of the joy you had when you first started.

Advent of Code puzzles in idiomatic Kotlin

Advent of Code is an annual December event, where holiday-themed puzzles are published every day from December 1 to December 25. With the permission of Eric Wastl, creator of Advent of Code, we'll show how to solve these puzzles using the idiomatic Kotlin style:

- Advent of Code 2025
- Advent of Code 2024
- Advent of Code 2023

- Advent of Code 2022
- Advent of Code 2021
- Advent of Code 2020

Get ready for Advent of Code

We'll take you through the basic tips on how to get up and running with solving Advent of Code challenges with Kotlin:

- Use this GitHub template to create projects
- Check out the welcome video by Kotlin Developer Advocate, Sebastian Aigner:

Watch video online.

Advent of Code 2022

Day 1: Calorie counting

Learn about the Kotlin Advent of Code template and convenience functions for working with strings and collections in Kotlin, such as `maxOf()` and `sumOf()`. See how extension functions can help you structure your solution in a nice manner.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 1 | Kotlin

Day 2: Rock paper scissors

Understand operations on the `Char` type in Kotlin, see how the `Pair` type and the `to` constructor work well with pattern matching. Understand how to order your own objects using the `compareTo()` function.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 2 | Kotlin

Day 3: Rucksack reorganization

Learn how the kotlinx.benchmark library helps you understand the performance characteristics of your code. See how set operations like `intersect` can help you select overlapping data, and see performance comparisons between different implementations of the same solution.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 3 | Kotlin

Day 4: Camp cleanup

See how `infix` and `operator` functions can make your code more expressive, and how extension functions for the `String` and `IntRange` types make it easy to parse input.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

 Advent of Code 2022 Day 4 | Kotlin

Day 5: Supply stacks

Learn about constructing more complex objects with factory functions, how to use regular expressions, and the double-ended `ArrayDeque` type.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

 Advent of Code 2022 Day 5 | Kotlin

Day 6: Tuning trouble

See more in-depth performance investigations with the kotlinx.benchmark library, comparing the characteristics of 16 different variations of the same solution.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

 Advent of Code 2022 Day 6 | Kotlin

Day 7: No space left on device

Learn how to model tree structures, and see a demo of generating Kotlin code programmatically.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

 Advent of Code 2022 Day 7 | Kotlin

Day 8: Treetop tree house

See the `sequence` builder in action, and how far a first draft of a program and an idiomatic Kotlin solution can differ (with special guest Roman Elizarov!).

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

 Advent of Code 2022 Day 8 | Kotlin

Day 9: Rope bridge

See the `run` function, labeled returns, and convenient standard library functions like `coerceIn`, or `zipWithNext`. See how you can construct lists of given sizes using the `List` and `MutableList` constructors, and get a peek at a Kotlin-based visualization of the problem statement.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 9 | Kotlin

Day 10: Cathode-ray tube

Learn how ranges and the `in` operator make checking ranges natural, how function parameters can be turned into receivers, and a brief exploration of the `tailrec` modifier.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 10 | Kotlin

Day 11: Monkey in the middle

See how you can move from mutable, imperative code to a more functional approach that makes use of immutable and read-only data structures. Learn about context receivers and how our guest built his own visualization library just for Advent of Code.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 11 | Kotlin

Day 12: Hill Climbing algorithm

Use queues, `ArrayDeque`, function references, and the `tailrec` modifier to solve path finding problems with Kotlin.

- Read the puzzle description on Advent of Code
- Check out the solution in the video:

Advent of Code 2022 Day 12 | Kotlin

Advent of Code 2021

Read our blog post about Advent of Code 2021

Day 1: Sonar sweep

Apply windowed and count functions to work with pairs and triplets of integers.

- Read the puzzle description on Advent of Code

- Check out the solution from Anton Arhipov on the Kotlin Blog or watch the video:

 Advent of Code 2021 in Kotlin, Day 1: Sonar Sweep

Day 2: Dive!

Learn about destructuring declarations and the `when` expression.

- Read the puzzle description on Advent of Code
- Check out the solution from Pasha Finkelshteyn on GitHub or watch the video:

 Advent of Code 2021 in Kotlin, Day 2: Dive!

Day 3: Binary diagnostic

Explore different ways to work with binary numbers.

- Read the puzzle description on Advent of Code
- Check out the solution from Sebastian Aigner on Kotlin Blog or watch the video:

 Advent of Code 2021 in Kotlin, Day 3: Binary Diagnostic

Day 4: Giant squid

Learn how to parse the input and introduce some domain classes for more convenient processing.

- Read the puzzle description on Advent of Code
- Check out the solution from Anton Arhipov on the GitHub or watch the video:

 Advent of Code 2021 in Kotlin, Day 4: Giant Squid

Advent of Code 2020

 You can find all the solutions for the Advent of Code 2020 puzzles in our GitHub repository.

Day 1: Report repair

Explore input handling, iterating over a list, different ways of building a map, and using the `let` function to simplify your code.

- Read the puzzle description on Advent of Code
- Check out the solution from Svetlana Isakova on the Kotlin Blog or watch the video:

 Learn Kotlin With the Kotlin Team: Advent of Code 2020 #1

Day 2: Password philosophy

Explore string utility functions, regular expressions, operations on collections, and how the `let` function can be helpful to transform your expressions.

- Read the puzzle description on Advent of Code

- Check out the solution from Svetlana Isakova on the Kotlin Blog or watch the video:

 Learn Kotlin with The Kotlin Team: Advent of Code 2020 #2

Day 3: Toboggan trajectory

Compare imperative and more functional code styles, work with pairs and the `reduce()` function, edit code in the column selection mode, and fix integer overflows.

- Read the puzzle description on Advent of Code
- Check out the solution from Mikhail Dvorkin on GitHub or watch the video:

 Learn Kotlin with the Kotlin Team: Advent of Code 2020 #3

Day 4: Passport processing

Apply the `when` expression and explore different ways of how to validate the input: utility functions, working with ranges, checking set membership, and matching a particular regular expression.

- Read the puzzle description on Advent of Code
- Check out the solution from Sebastian Aigner on the Kotlin Blog or watch the video:

 Learn Kotlin with the Kotlin Team: Advent of Code 2020 #4

Day 5: Binary boarding

Use the Kotlin standard library functions (`replace()` , `toInt()` , `find()`) to work with the binary representation of numbers, explore powerful local functions, and learn how to use the `max()` function in Kotlin 1.5.

- Read the puzzle description on Advent of Code
- Check out the solution from Svetlana Isakova on the Kotlin Blog or watch the video:

 Learn Kotlin with the Kotlin Team: Advent of Code 2020 #5

Day 6: Custom customs

Learn how to group and count characters in strings and collections using the standard library functions: `map()` , `reduce()` , `sumOf()` , `intersect()` , and `union()` .

- Read the puzzle description on Advent of Code
- Check out the solution from Anton Arhipov on the Kotlin Blog or watch the video:

 Learn Kotlin with the Kotlin Team: Advent of Code 2020 #6

Day 7: Handy haversacks

Learn how to use regular expressions, use Java's `compute()` method for HashMaps from Kotlin for dynamic calculations of the value in the map, use the `forEachLine()` function to read files, and compare two types of search algorithms: depth-first and breadth-first.

- Read the puzzle description on Advent of Code
- Check out the solution from Pasha Finkelshteyn on the Kotlin Blog or watch the video:

Learn Kotlin with the Kotlin Team: Advent of Code 2020 #7

Day 8: Handheld halting

Apply sealed classes and lambdas to represent instructions, apply Kotlin sets to discover loops in the program execution, use sequences and the `sequence { }` builder function to construct a lazy collection, and try the experimental `measureTimedValue()` function to check performance metrics.

- Read the puzzle description on Advent of Code
- Check out the solution from Sebastian Aigner on the Kotlin Blog or watch the video:

Learn Kotlin with the Kotlin Team: Advent of Code 2020 #8

Day 9: Encoding error

Explore different ways to manipulate lists in Kotlin using the `any()`, `firstOrNull()`, `firstNotNullOfOrNull()`, `windowed()`, `takeIf()`, and `scan()` functions, which exemplify an idiomatic Kotlin style.

- Read the puzzle description on Advent of Code
- Check out the solution from Svetlana Isakova on the Kotlin Blog or watch the video:

Learn Kotlin with the Kotlin Team: Advent of Code 2020 #9

What's next?

- Complete more tasks with Kotlin Koans
- Create working applications with the free Kotlin Core track by JetBrains Academy

Learning Kotlin with JetBrains Academy plugin

With the JetBrains Academy plugin, available both in Android Studio and IntelliJ IDEA, you can learn Kotlin through code practicing tasks.

Take a look at the Learner Start Guide, which will get you started with the Kotlin Koans course inside IntelliJ IDEA. Solve interactive coding challenges and get instant feedback right inside the IDE.

If you want to use the JetBrains Academy plugin for teaching, read Teaching Kotlin with JetBrains Academy plugin.

Teaching Kotlin with JetBrains Academy plugin

With the JetBrains Academy plugin, available both in Android Studio and IntelliJ IDEA, you can teach Kotlin through code practicing tasks.

Take a look at the Educator Start Guide to learn how to create a simple Kotlin course that includes a set of programming tasks and integrated tests.

If you want to use the JetBrains Academy plugin to learn Kotlin, read Learning Kotlin with JetBrains Academy plugin.

FAQ

What is Kotlin?

Kotlin is an open-source statically typed programming language that targets the JVM, Android, JavaScript, Wasm, and Native. It's developed by JetBrains. The project started in 2010 and was open source from very early on. The first official 1.0 release was in February 2016.

What is the current version of Kotlin?

The currently released version is 2.4.20, published on September 7, 2026.
You can find more information on GitHub.

Is Kotlin free?

Yes. Kotlin is free, has been free, and will remain free. It is developed under the Apache 2.0 license, and the source code is available on GitHub.

Is Kotlin an object-oriented language or a functional one?

Kotlin has both object-oriented and functional constructs. You can use it in both OO and FP styles, or mix elements of the two. With first-class support for features such as higher-order functions, function types, and lambdas, Kotlin is a great choice if you're doing or exploring functional programming.

What advantages does Kotlin give me over the Java programming language?

Kotlin is more concise. Rough estimates indicate approximately a 40% cut in the number of lines of code. It's also more type-safe — for example, support for non-nullable types makes applications less prone to NPE's. Other features including smart casting, higher-order functions, extension functions, and lambdas with receivers provide the ability to write expressive code as well as facilitating creation of DSL.

Is Kotlin compatible with the Java programming language?

Yes. Kotlin is 100% interoperable with the Java programming language, and major emphasis has been placed on making sure that your existing codebase can interact properly with Kotlin. You can easily call Kotlin code from Java and Java code from Kotlin. This makes adoption much easier and lower-risk. There's also an automated Java-to-Kotlin converter built into the IDE that simplifies migration of existing code.

What can I use Kotlin for?

Kotlin can be used for any kind of development, be it backend, client-side web, Android, or multiplatform library. With Kotlin/Native currently in the works, support for other platforms such as embedded systems, macOS, and iOS. People are using Kotlin for mobile and server-side applications, client-side with JavaScript or JavaFX, and data science, just to name a few possibilities.

Can I use Kotlin for Android development?

Yes. Kotlin is supported as a first-class language on Android. There are hundreds of applications already using Kotlin for Android, such as Basecamp, Pinterest, and more. For more information, check out the resource on Android development.

Can I use Kotlin for backend development?

Yes. Kotlin is 100% compatible with the JVM, and as such you can use any existing frameworks such as Spring Boot, vert.x, or JSF. In addition, there are specific frameworks written in Kotlin, such as Ktor. For more information, check out the Backend development overview.

Can I use Kotlin for web development?

Yes. For backend web development, Kotlin works well with frameworks such as Ktor and Spring, enabling you to build server-side applications efficiently. Additionally, you can use Kotlin/Wasm for client-side web development. Learn how to get started with Kotlin/Wasm.

Can I use Kotlin for desktop development?

Yes. You can use any Java UI framework such as JavaFx, Swing, or other. In addition, there are Kotlin-specific frameworks such as TornadoFX.

Can I use Kotlin for native development?

Yes. Kotlin/Native is available as a part of Kotlin. It compiles Kotlin to native code that can run without a VM. You can try it on popular desktop and mobile platforms and even some IoT devices. For more information, check out the Kotlin/Native documentation.

What IDEs support Kotlin?

Kotlin has full out-of-the-box support in IntelliJ IDEA and Android Studio with an official Kotlin plugin developed by JetBrains. You can also install the official Kotlin by JetBrains extension for Visual Studio Code, powered by Kotlin Language Server, which is in Alpha.

Other IDEs and code editors only have Kotlin community-supported plugins.

You can also try Kotlin Playground for writing, running, and sharing Kotlin code in your browser. In addition, a command line compiler is available, which provides straightforward support for compiling and running applications.

What build tools support Kotlin?

On the JVM side, the main build tools include Gradle and Maven. There are also some build tools available that target client-side JavaScript.

What does Kotlin compile down to?

When targeting the JVM, Kotlin produces Java-compatible bytecode.

When targeting JavaScript, Kotlin transpiles to ES5.1 and generates code which is compatible with module systems including AMD and CommonJS.

When targeting native, Kotlin will produce platform-specific code (via LLVM).

Which versions of JVM does Kotlin target?

Kotlin lets you choose the version of JVM for execution. By default, the Kotlin/JVM compiler produces Java 8 compatible bytecode. If you want to make use of optimizations available in newer versions of Java, you can explicitly specify the target Java version from 9 to 26. Note that in this case, the resulting bytecode might not run on lower versions. Starting with Kotlin 1.5, the compiler does not support producing bytecode compatible with Java versions below 8.

Is Kotlin hard?

Kotlin is inspired by existing languages such as Java, C#, JavaScript, Scala, and Groovy. We've tried to ensure that Kotlin is easy to learn, so that people can easily jump on board, reading and writing Kotlin in a matter of days. Learning idiomatic Kotlin and using some more of its advanced features can take a little longer, but overall it is not a complicated language.
For more information, check out our learning materials.

What companies are using Kotlin?

There are too many companies using Kotlin to list, but some more visible companies that have publicly declared usage of Kotlin, be this via blog posts, GitHub repositories or talks include Square, Pinterest, and Basecamp.

Who develops Kotlin?

Kotlin is developed by a team of engineers at JetBrains (current team size is 100+). The lead language designer is Michail Zarečenskij. In addition to the core team, there are also over 250 external contributors on GitHub.

Where can I learn more about Kotlin?

The best place to start is our website. To start with Kotlin, you can install one of the official IDEs or try it online.

Are there any books on Kotlin?

There are a number of books available for Kotlin. Some of them we have reviewed and can recommend to start with. They are listed on the Books page. For more books, see the community-maintained list at kotlin.link.

Are any online courses available for Kotlin?

You can learn all the Kotlin essentials while creating working applications with the Kotlin Core track by JetBrains Academy.

A few other courses you can take:

- Pluralsight Course: Getting Started with Kotlin by Kevin Jones
- O'Reilly Course: Introduction to Kotlin Programming by Hadi Hariri

You can also check out the other tutorials and content on our YouTube channel.

Does Kotlin have a community?

Yes! Kotlin has a very vibrant community. Kotlin developers hang out on the Kotlin forums, StackOverflow, and more actively on the Kotlin Slack (with close to 30000 members as of April 2020).

Are there Kotlin events?

Yes! There are many User Groups and Meetups now focused exclusively around Kotlin. You can find a list on the website. In addition, there are community-organized Kotlin Nights events around the world.

Is there a Kotlin conference?

Yes! KotlinConf is an annual conference hosted by JetBrains, which brings together developers, enthusiasts, and experts from around the world to share their knowledge and experience with Kotlin.

In addition to technical talks and workshops, KotlinConf also offers networking opportunities, community interactions, and social events where attendees can connect with fellow Kotliners and exchange ideas. It serves as a platform for fostering collaboration and community building within the Kotlin ecosystem.

Kotlin is also being covered in different conferences worldwide. You can find a list of upcoming talks on the website.

Is Kotlin on social media?

Yes. Subscribe to the Kotlin YouTube channel and follow Kotlin on Twitter or on Bluesky.

Any other online Kotlin resources?

The website has a bunch of online resources, including Kotlin Digests by community members, a newsletter, a podcast, and more.

Where can I get an HD Kotlin logo?

Logos can be downloaded here. When using the logos, please follow simple rules in the `guidelines.pdf` inside the archive and Kotlin brand usage guidelines.

For more information, check out the page about Kotlin brand assets.

Google Summer of Code with Kotlin

The Kotlin Foundation provides mentorship for Google Summer of Code (GSoC), a global online program that introduces new contributors to open-source development.

Learn more about GSoC on the official Google Summer of Code website.

GSoC 2026: project ideas

The Kotlin Foundation has published a list of project ideas for Google Summer of Code 2026. If you're interested in contributing, check out the available projects and guidelines: Google Summer of Code with Kotlin 2026.

Past GSoC projects with Kotlin

You can explore past Google Summer of Code projects and ideas with Kotlin:

- Google Summer of Code with Kotlin 2025
- Google Summer of Code with Kotlin 2024
- Google Summer of Code with Kotlin 2023

Google Summer of Code with Kotlin 2026

This article contains the list of project ideas for Google Summer of Code with Kotlin 2026, and contributor guidelines

Kotlin resources:

- Kotlin GitHub repository
- Kotlin Slack and the #gsoc Slack channel

If you got any questions, contact us via gsoc@kotlinfoundation.org

Kotlin contributor guidelines for Google Summer of Code (GSoC)

Getting started

1. Check out the GSoC FAQ and the program announcement.
2. Familiarize yourself with the Kotlin language:
   - The official Kotlin website is a great place to start.
   - Read the official documentation to get a better understanding of the language.
   - Take a look at the Kotlin courses on JetBrains Academy or the Android team's Training options.
   - Follow the Kotlin X or Kotlin Bluesky accounts to stay up to date on the latest news and developments.
   - Check out the Kotlin YouTube channel for tutorials, tips, and the latest updates.
3. Get to know the Kotlin open source community:
   - Explore the general Kotlin contribution guidelines.
   - Join the Kotlin Slack channel to connect with other developers and get help with any questions you may have.

- Join the #gsoc channel to ask questions and get support from the GSoC team.

How to apply

1. Check out the project ideas and select the one you would like to work on.
2. If you are not familiar with Kotlin, read the introductory info on the Kotlin website.
3. Refer to the GSoC contributor guidelines.
4. Apply via the GSoC website.
    - We suggest that you write a working code sample relevant to the proposed project. You can also show us any code sample that you are particularly proud of.
    - Describe why you are interested in Kotlin and your experience with it.
    - If you participate in open source projects, please reference your contribution history.
    - If you have a GitHub, Twitter account, blog, or portfolio of technical or scientific publications, please reference them as well.
    - Disclose any conflicts with the GSoC timeline due to other commitments, such as exams and vacations.

Thank you! We look forward to reading your applications!

Project ideas

Kotlin Compiler Fuzzer (Kai) [Hard, 350 hrs]

In recent years, fuzzing has become a widely used technique for finding complex bugs in software. The Kotlin compiler is no exception: previous fuzzing efforts resulted in more than 200 deduplicated bugs across different compiler subsystems.

However, the existing fuzzer implementation is now obsolete and cannot be reasonably evolved further. The goal of this project is to build a new Kotlin compiler fuzzer, **Kai**, from scratch, based on previous experience and modern tools and techniques.

The main goal of this internship is to establish a solid foundation for future development of the fuzzer. The focus areas include:

- Designing a fuzzer architecture that supports pluggability
- Selecting tools for generating, mutating, and processing Kotlin code
- Defining reliable ways to detect compiler failures
- Designing proper workflows for collecting, classifying, and handling discovered issues

As a deliverable, we aim to create a prototype Kotlin compiler fuzzer that is modular and easy to evolve, unlike a monolithic implementation. Finding real compiler bugs would be a great bonus, but it is not the primary goal of this internship.

If you have preliminary questions about the project, contact the mentor at: marat.akhin [at] jetbrains.com

Expected outcomes

A prototype Kotlin compiler fuzzer with a pluggable architecture that supports future evolution.

Skills required (must-have)

- Proficiency in Kotlin or another JVM-based language
- Technical English sufficient for reading relevant papers and documentation
- Basic understanding of compilers

Skills required (nice-to-have)

- Familiarity with fuzzing or other forms of program analysis
- Experience with Kotlin compiler plugins, IDE plugins, or other pluggable systems
- Experience with greenfield developer tooling projects

What you will learn

- Hands-on experience with compiler fuzzing
- How internal developer tooling is designed and built
- How to design and implement pluggable systems

Possible mentor

Marat Akhin, JetBrains

This project includes a test task. Please email education@kotlinlang.org to receive the details.

Swift-to-Kotlin interop (PoC) [Hard, 350 hrs]

Modern software projects rarely live in a single language ecosystem. On Apple platforms, Swift is the primary language, while Kotlin is widely used for shared and cross-platform business logic. However, there is currently no straightforward way to import Swift APIs directly into Kotlin.

In this project, you will build on an existing open-source Swift–Java bridge and add Kotlin/Native as a target runtime. This includes designing how Swift APIs are exposed to Kotlin/Native, how calls cross the Swift/Kotlin boundary, and how object lifetimes are managed across runtimes.

The goal is to create a proof of concept for Swift-to-Kotlin/Native interop, document design decisions and trade-offs, and evaluate limitations and future directions.

Expected outcomes

A proof of concept for Swift-to-Kotlin/Native interop, with documented design decisions, trade-offs, limitations, and future directions.

Skills required (must-have)

- Currently pursuing or recently completed a degree in Computer Science or a related field
- Familiarity with Swift
- Interest in programming languages and interoperability

Skills required (nice-to-have)

- Familiarity with Kotlin

Possible mentor

Artem Olkov, JetBrains

This project includes a test task. Please email education@kotlinlang.org to receive the details.

Tail call support in the Kotlin/Wasm backend [Medium, 90 hrs]

This project focuses on integrating the tail call proposal into the Kotlin/Wasm backend. The intern will design and implement tail call support and evaluate its impact through benchmarking.

Expected outcomes

Design and implementation of tail call support for Kotlin/Wasm, with benchmarks and evaluation.

Skills required (preferred)

General familiarity with interpreters and compilers, and interest in optimization and benchmarking.

Possible mentor

Charlie Zhang, JetBrains

Kotlin Education landscape report [Medium, 175 hrs]

Kotlin is taught and used in educational settings worldwide. This project aims to create a structured, up-to-date overview of where and how Kotlin is taught.

Expected outcomes

- A “Kotlin in Education” report highlighting trends and gaps
- Reusable datasets for internal and public use
- Input for future strategy

Skills required (preferred)

- Research and data analysis skills
- Interest in programming education and developer ecosystems

Possible mentor

Ksenia Shneyveys, JetBrains

Google Summer of Code with Kotlin 2025

This article contains the list of project ideas for Google Summer of Code with Kotlin 2025, and contributor guidelines

Kotlin resources:

- Kotlin GitHub repository
- Kotlin Slack and the #gsoc Slack channel

If you got any questions, contact us via gsoc@kotlinfoundation.org

Kotlin contributor guidelines for Google Summer of Code (GSoC)

Getting started

1. Check out the GSoC FAQ and the program announcement.

2. Familiarize yourself with the Kotlin language:
    - The official Kotlin website is a great place to start.
    - Read the official documentation to get a better understanding of the language.
    - Take a look at the Kotlin courses on JetBrains Academy or the Android team's Training options.
    - Follow the Kotlin X or Kotlin Bluesky accounts to stay up to date on the latest news and developments.
    - Check out the Kotlin YouTube channel for tutorials, tips, and the latest updates.
3. Get to know the Kotlin open source community:
    - Explore the general Kotlin contribution guidelines.
    - Join the Kotlin Slack channel to connect with other developers and get help with any questions you may have.
    - Join the #gsoc channel to ask questions and get support from the GSoC team.

How to apply

1. Check out the project ideas and select the one you would like to work on.
2. If you are not familiar with Kotlin, read the introductory info on the Kotlin website.
3. Refer to the GSoC contributor guidelines.
4. Apply via the GSoC website.
    - We suggest that you write a working code sample relevant to the proposed project. You can also show us any code sample that you are particularly proud of.
    - Describe why you are interested in Kotlin and your experience with it.
    - If you participate in open source projects, please reference your contribution history.
    - If you have a GitHub, Twitter account, blog, or portfolio of technical or scientific publications, please reference them as well.
    - Disclose any conflicts with the GSoC timeline due to other commitments, such as exams and vacations.

Thank you! We look forward to reading your applications!

Project ideas

Build Server Protocol: add Kotlin support [Hard, 350 hrs]

The Kotlin team wants to expand official Kotlin support not only for Gradle and Maven build systems, but any other build system as well and support them natively in JetBrains IDEs with minimal effort. On the other hand, we also want to provide basic Kotlin support in non-JetBrains IDEs – one part of such support is being able to get Kotlin-specific information from any build system supporting Kotlin.

The solution to these requirements could be a Build Server Protocol (BSP) which provides an abstraction layer between the build system and IDE.

The goal of this project would be implementing a prototype which uses the BSP protocol to get all the required information for IntelliJ IDEA from a user project so that it will be possible to work with Kotlin code in the project. To limit the scope of this prototype, the user project will use Gradle to build itself automatically.

Preferred skills

- Knowledge of Kotlin
- Understanding of how to write Gradle plugins
- *Bonus*: understanding of how to write plugins for IntelliJ IDEA

Possible mentors

Yahor Berdnikau, Bálint Hegyi, and Reinhold Degenfellner

Tasks for applicants

- **Task #1**. Why are you interested in this project?
- **Task #2**. Practice assignment: Create a Gradle plugin which exposes a specific task. This task should, in the presence of the Kotlin Gradle Plugin, retrieve all the Kotlin sources' structures and output them. Including tests would be a bonus.

Support Android and iOS targets in Kotlin Multiplatform for Gemini using Vertex AI in Firebase [Medium, 175 hrs]

This project aims to create an open-source Kotlin Multiplatform (KMP) library that supports Gemini using Vertex AI in Firebase on at least Android and iOS. It will showcase best practices in creating KMP libraries for existing services, with a focus on appropriate production implementation (for example, proper API key management, user-managed API keys support, and client throttling).

Expected outcomes

- A new Kotlin Multiplatform library with support for an existing Google service
- Sample code and documentation

Preferred skills

- Kotlin
- Kotlin Multiplatform
- Mobile development (Android and iOS)

Possible mentors

Matt Dyor, and the Google team

Add Kotlin Multiplatform support in Bazel [Hard, 350 hrs]

Bazel's support for Kotlin is evolving, but proper Kotlin Multiplatform (KMP) integration remains a challenge. This project aims to improve Bazel's KMP support by addressing dependency resolution issues, enhancing `rules_kotlin` and `rules_jvm_external` compatibility, and enabling cross-platform builds.

Key improvements will focus on handling platform-specific dependencies (expect/actual mechanisms), improving Gradle metadata support, and ensuring a smoother developer experience for KMP in Bazel.

Expected outcomes

- Enhanced dependency resolution for Kotlin Multiplatform in Bazel
- Improved integration with `rules_kotlin` and `rules_jvm_external`
- A working KMP build setup in Bazel for seamless multiplatform development

Preferred skills

- Kotlin Multiplatform and Gradle
- Bazel build system
- Dependency resolution strategies

Possible mentors

Shauvik Roy Choudhary, and the Uber team

Kotlin Language Server (LSP) [Hard, 350 hrs]

The Language Server Protocol (LSP) is a widely adopted standard that enables code intelligence features such as autocompletion, go-to definition, and refactoring across different editors and IDEs. While there is currently no official Kotlin LSP server, there is significant demand for one in the community. A publicly maintained, community-driven implementation can support broad use cases, including code migration, AI-powered code assistance, and seamless integration into various development environments.

This project aims to develop a Kotlin LSP implementation, ensuring compatibility with key LSP features and broadening Kotlin's accessibility across development environments.

Expected outcomes

Develop a Kotlin LSP implementation

Preferred skills

- Kotlin
- Language Server Protocol (LSP)
- Plugin or extension development for IDEs

Possible mentors

Shauvik Roy Choudhary, and the Uber team

Maven Central publishing plugin for Gradle with new APIs [Medium, 175 hrs]

Maven Central is one of the most popular Maven repositories for publishing JVM-focused libraries and projects. It is actively used by Apache Maven or Gradle-based open-source projects, and based on Sonatype Nexus v2, pending migration to a newer version. There is ongoing migration of open source projects to a new Maven Central Instance, which has a very different API implementation and needs special support in the build tool plugins. Developing a Gradle plugin that is compatible with the new Maven Central publication APIs would help the library authors building with Gradle to have a smooth experience with the new process.

Currently, there are multiple implementations of Maven Central publishing plugins in Gradle, for example, the Maven Publish Plugin or the New Maven Central Publishing, which already tries to adopt the new APIs. During the application or the community bonding phase, a potential contributor would need to review the implementations and either suggest an existing plugin to update or decide to build a new plugin or fork. The deliverables would include either a new version of an existing plugin for Maven Central publishing or a new plugin for Gradle. We anticipate the implementation to be in Kotlin or Java and to have proper test coverage and documentation. Additional deliverables may include Kotlin DSL extensions to simplify the use of the plugins and Declarative Gradle extensions.

Expected outcomes

- Updated Maven Central publishing plugin or a new plugin

Preferred skills

- Kotlin
- Gradle
- Maven Repositories

Possible mentors

Oleg Nenashev, and the Gradle team

Improving Configuration Cache and lock contention in key Gradle plugins [Easy to Hard, 90 hrs to 350 hrs]

Gradle is working on Isolated Projects – a new feature that greatly extends the configuration cache to further improve performance, particularly the performance of Android Studio and IntelliJ IDEA sync. From the developer experience standpoint, it is one of the most expected features in Gradle.

One of the problems for Isolated projects is the lock contention in the Gradle core, with plugins sometimes getting in the way of parallel execution. We would like to reduce the lock contention, especially in the key Gradle Build Tool plugins for Java, Kotlin, Android, and Kotlin Multiplatform ecosystems. Contributors are welcome to choose the deliverables based on their interests and the desired project size.

Potential deliverables include but are not limited to:

- Embed the Configuration Cache Report tool into the Gradle Profiler (or "implement a GitHub Action for it")
- Profile Gradle and a few popular Gradle plugins in various projects, with automation of the test suite on GHA
- Determine potential areas and plugins where lock contention can be reduced, with or without Configuration Cache
- While around, contribute to other areas of Configuration Cache compatibility in the target plugins
- Implement some of the discovered improvements

Expected outcomes

Implementing extensibility features in the Kotlin DSL for Gradle and improving support for common project integrations

Preferred skills

- Kotlin
- Gradle
- Java
- Performance analysis
- Profiling

Possible mentors

Oleg Nenashev, Laura Kassovic

Gradle convention plugin for developing Jenkins plugins [Easy to Hard, 90 hrs to 350 hrs]

There are more than 50 Jenkins plugins that are implemented with Gradle. There is a Gradle JPI plugin, but it is not fully compliant with Jenkins hosting requirements and needs an update. In this project idea, the aim would be to recover the Gradle developer flow for Jenkins, reach feature parity with the Apache Maven flow (Parent POM, Plugin Compatibility Tester, Jenkins Bill of Materials, and others), and to improve the developer experience for those who develop Jenkins plugins with Gradle.

Contributors are welcome to choose the deliverables based on their interest and the desired project size.

Potential deliverables include but are not limited to:

- Refreshing the Gradle JPI plugin and making it compliant with hosting best practices
- Migrating the Gradle JPI plugin codebase from Groovy to Kotlin
- Implementing a new convention plugin for Jenkins Plugins that would cover the main features of Jenkins plugin Parent POM, with Kotlin and Kotlin DSL. This would include not just building the plugin, but also testing and static analysis according to Jenkins' best practices
- Adopting the refreshed plugin and/or the convention plugin in the most popular Gradle plugin, including the Gradle plugin itself
- Integrating the Gradle plugin into the Plugin Compatibility Tester and Bill of Materials
- Documenting the updated Gradle development flow for Jenkins plugins

Expected outcomes

Updated Gradle JPI plugin and/or new convention plugin for Jenkins, published on Jenkins Update Center and the Gradle Plugin Portal

Preferred skills

- Kotlin DSL
- Kotlin
- Gradle
- Jenkins
- Java

Possible mentors

Oleg Nenashev, Stefan Wolf

Kotlin DSL and Declarative Gradle documentation samples test framework [Easy to Medium, 90 hrs to 175 hrs]

Many projects, including Gradle, have a lot of Kotlin DSL samples and code snippets (see the Gradle Docs for examples). Testing them against multiple versions poses certain challenges because the snippets often represent incomplete code for the sake of brevity. We would like to build a test framework that simplifies the verification of those samples within a unit test framework (Kotest or JUnit 5) on GitHub Actions or TeamCity. Later we would be interested in doing the same for Declarative Gradle samples.

Expected outcomes

Implementing extensibility features in the Kotlin DSL for Gradle and improving support for common project integrations

Preferred skills

- Kotlin
- Gradle
- Java
- Static analysis

Possible mentors

Oleg Nenashev, Laura Kassovic

IntelliJ Platform Gradle Plugin – Gradle Reporting and Parallel Verifications [Medium, 175 hrs]

The IntelliJ Platform Gradle Plugin, a plugin for the Gradle build system, simplifies configuring your environment for building, testing, verifying, and publishing plugins for IntelliJ-based IDEs. The plugin manages the build, test, and verification steps while keeping up with the constant changes introduced in the IntelliJ Platform. The IntelliJ Platform Gradle Plugin is used by JetBrains, third-party developers, and external companies to integrate their workflows with JetBrains tools.

Expected outcomes

- Introduce Gradle Reporting to provide detailed, configurable verification task reports.
- Utilize Gradle Worker API to enable parallel execution of the `verifyPlugin` task against multiple IntelliJ Platform versions, reducing the task execution time.
- Explore additional Gradle enhancements to further improve plugin development workflows.

Preferred skills

- Kotlin
- Gradle
- IntelliJ Platform

Possible mentors

Jakub Chrzanowski, JetBrains

Add More Kotlin OpenRewrite Recipes [Medium, 175 hrs]

OpenRewrite is a powerful framework for automating code migrations and refactorings in a structured manner. While OpenRewrite has strong support for Java, the Kotlin ecosystem would benefit from a more comprehensive set of OpenRewrite recipes to help developers seamlessly migrate their codebases.

This project aims to expand the Kotlin OpenRewrite recipe collection by adding more automated transformations, such as migrating Java-based AutoValue classes to idiomatic Kotlin data classes, modernizing Kotlin code to follow best practices, and enabling more seamless migrations across Kotlin versions. These recipes will help Kotlin developers maintain clean, up-to-date, and idiomatic codebases with minimal manual effort.

Expected outcomes

- Development of new OpenRewrite recipes for Kotlin code migrations

Preferred skills

- Kotlin

- OpenRewrite framework
- Java-to-Kotlin migration strategies

Possible mentors

Shauvik Roy Choudhary, and the Uber team

Add BOM Support to Bazel `rules_jvm_external` [Hard, 350 hrs]

Bazel's `rules_jvm_external` provides a structured way to declare external Java dependencies, but it currently lacks proper support for Bill of Materials (BOM) files. BOM files are widely used in Maven and Gradle to manage dependencies in a consistent manner without requiring developers to specify individual versions. This project aims to enhance `rules_jvm_external` by adding BOM support, allowing developers to use BOM-based dependency resolution within Bazel. The project may involve contributing to an existing open-source effort or implementing BOM support directly in `rules_jvm_external`, ensuring compatibility with widely used dependency management approaches.

Expected outcomes

- Implementation of BOM support in Bazel `rules_jvm_external`
- Improved dependency resolution and usability for Bazel users
- Documentation and examples for using BOM support in Bazel

Preferred skills

- Starlark (Bazel's scripting language)
- Bazel build system
- Dependency resolution strategies

Possible mentors

Shauvik Roy Choudhary, and the Uber team

Clean and actionable reporting for Gradle code quality plugins for Kotlin [Easy to Medium, 90 hrs to 175 hrs]

Gradle recently introduced a new Problems API that allows Gradle and third-party plugins to propagate issues and warnings in a unified way. This API provides clean and actionable error reporting and more insights into the console output, dedicated HTML reports, and connected observability tools. IDEs such as IntelliJ IDEA or Android Studio can also access the details via Gradle's API integration tool, and can show warnings right in the code editor. Several core features and plugins have already adopted the Problems API: Java compilation, dependency resolution errors, deprecation warnings, etc. We want the code quality plugins for Kotlin to adopt this API, too; it would significantly improve the developer experience for 100,000+ Kotlin developers using Gradle.

In this project, we invite contributors to choose a number of Kotlin code quality plugins, such as Ktlint, Detekt, Diktat, ArchUnit, or Checkstyle for Kotlin, and integrate them with Problems API. You can also work on integrating a similar analysis for Gradle builds defined with KotlinDSL.

Expected outcomes

- Implement Problems API integration in the mentioned plugins

Preferred skills

- Kotlin

- Gradle

Possible mentors

Oleg Nenashev, Balint Hegyi, Reinhold Degenfellner

Google Summer of Code with Kotlin 2024

This article contains the list of project ideas for Google Summer of Code with Kotlin 2024, and contributor guidelines

Kotlin resources:

- Kotlin GitHub repository
- Kotlin Slack and the #gsoc Slack channel

If you got any questions, contact us via gsoc@kotlinfoundation.org

Kotlin contributor guidelines for Google Summer of Code (GSoC)

Getting started

1. Check out the GSoC FAQ and the program announcement.
2. Familiarize yourself with the Kotlin language:
   - The official Kotlin website is a great place to start.
   - Read the official documentation to get a better understanding of the language.
   - Take a look at the Kotlin courses on JetBrains Academy or the Android team's Training options.
   - Follow the Kotlin X or Kotlin Bluesky accounts to stay up to date on the latest news and developments.
   - Check out the Kotlin YouTube channel for tutorials, tips, and the latest updates.
3. Get to know the Kotlin open source community:
   - Explore the general Kotlin contribution guidelines.
   - Join the Kotlin Slack channel to connect with other developers and get help with any questions you may have.
   - Join the #gsoc channel to ask questions and get support from the GSoC team.

How to apply

1. Check out the project ideas and select the one you would like to work on.
2. If you are not familiar with Kotlin, read the introductory info on the Kotlin website.
3. Refer to the GSoC contributor guidelines.
4. Apply via the GSoC website.
   - We suggest that you write a working code sample relevant to the proposed project. You can also show us any code sample that you are particularly proud of.

- Describe why you are interested in Kotlin and your experience with it.
- If you participate in open source projects, please reference your contribution history.
- If you have a GitHub, Twitter account, blog, or portfolio of technical or scientific publications, please reference them as well.
- Disclose any conflicts with the GSoC timeline due to other commitments, such as exams and vacations.

Thank you! We look forward to reading your applications!

Project ideas

Incremental compilation for the Kotlin-to-WebAssembly compiler [Hard, 350 hrs]

Incremental compilation is a technique that helps increase compilation speed by recompiling only changed files instead of your whole program (also known as performing a clean build). The Kotlin-to-Wasm compiler currently supports only clean builds, but during this project, we will enhance it to support incremental compilation, too.

Expected outcomes

Implementation of the incremental compilation feature in the Kotlin-to-WebAssembly compiler, contributing to faster development workflows.

Skills required (preferred)

Kotlin

Possible mentor

Artem Kobzar, JetBrains

Compose Multiplatform with Node.js native bindings for Skia [Hard, 350 hrs]

Compose Multiplatform is a declarative framework for sharing UIs built with Kotlin across multiple platforms. The current approach to rendering desktop applications uses the JVM as a platform, but what if we use Compose Multiplatform for Web and try to run an application outside the browser with Skia's native bindings? Will this improve desktop applications performance and memory consumption? Or will it do the opposite? We'll find out in this project!

Expected outcomes

Integration of Skia bindings with Compose Multiplatform and evaluation of performance impact on desktop applications.

Skills required (preferred)

Kotlin, Node.js, C++, or Rust

Possible mentor

Artem Kobzar, JetBrains

Compose Multiplatform component gallery generator [Medium, 350 hrs]

Compose Multiplatform is a declarative framework for sharing UIs built with Kotlin across multiple platforms. At the beginning of the React era of web development, Storybook was created, and Storybook's proposed approach of describing component states and generating the whole UI library gallery is still one of the essential approaches

to documentation in web development. Can we do the same with Compose Multiplatform, using it to generate a gallery of web UI elements, as well as galleries for mobile and desktop? Let's give it a try in this project.

Expected outcomes

Creation of a tool to generate UI component galleries for web, mobile, and desktop platforms using Compose Multiplatform.

Skills required (preferred)

Kotlin, Jetpack Compose, UI/UX Design

Possible mentor

Artem Kobzar, JetBrains

Kotlin DSL improvements for declarative Gradle [Medium, 175 hrs]

Last November, the Gradle team announced the new Declarative Gradle project, introducing a higher level Kotlin DSL in the project. We invite GSoC contributors to join us and work on improving the developer experience of the new DSL, in particular by implementing extensibility in Gradle plugins to support the most common Kotlin and Java project integrations: static analysis, test frameworks like Kotest and others.

Expected outcomes

Implementing extensibility features in the Kotlin DSL for Gradle and improving support for common project integrations.

Skills required (preferred)

Kotlin, Gradle, Java, Static Analysis

Possible mentor

Oleg Nenashev, Gradle

Gradle guidelines

Kotlin DSL documentation samples test framework [Easy or Medium, 90 hrs or 175 hrs]

Many projects, including Gradle, have a lot of Kotlin DSL samples and code snippets (see the Gradle Docs for examples). Testing them against multiple versions poses certain challenges because the snippets often represent incomplete code for the sake of brevity. We would like to build a test framework that simplifies the verification of those samples within a unit test framework (Kotest or JUnit 5) on GitHub Actions and Teamcity.

Expected outcomes

Implementation of a basic test framework for Kotlin DSL samples, integrated with GitHub Actions for continuous testing.

Skills required (preferred)

Kotlin, Testing Frameworks, CI/CD

Possible mentor

Oleg Nenashev, Gradle

Gradle guidelines

Gradle build server – support for Android projects [Medium or Hard, 175 hrs or 350 hrs]

Kotlin and Gradle are the default choices for building Android projects. In November 2023, the Microsoft team announced the Gradle Build Server project, which is a Gradle-specific implementation of the Build Server Protocol (BSP). It would be great to introduce full support for Android builds there. For smaller-scope projects, it is possible to implement auto-discovery and cancellation for Gradle tasks in the Gradle Build Server.

Expected outcomes

Implementation of Android project support in the Gradle Build Server, including auto-discovery and task cancellation.

Skills required (preferred)

Kotlin, Gradle, Android Development, Visual Studio Code

Possible mentor

Oleg Nenashev, Gradle

Gradle guidelines

Implement memory usage profiling for Kotlin/Native benchmarks [Medium, 175 hrs]

The kotlinx-benchmark library, an open-source toolkit, facilitates the benchmarking of Kotlin code across various platforms. It currently features GC profiling for the JVM, detailing each benchmark method's allocation rate. This project aims to extend similar profiling capabilities to Kotlin/Native, advancing toward uniform benchmarking capabilities across platforms.

The contributor will collaborate closely with the Kotlin/Native team to create an API for accessing allocation data from the Kotlin/Native memory manager. The objective is to generate reports that align with the JVM format, ensuring the consistency of data presentation across platforms. Furthermore, the project involves identifying and rectifying any discrepancies in reporting formats for other library features, thereby standardizing the benchmarking output for comprehensive cross-platform analysis.

Expected outcomes

Implementation of memory usage profiling in kotlinx-benchmark for Kotlin/Native and standardized benchmarking output.

Skills required (preferred)

Kotlin, Kotlin/Native, Benchmarking, Memory Profiling

Possible mentor

Abduqodiri Qurbonzoda, JetBrains
Alexander Shabalin, JetBrains

Support Android target in kotlinx-benchmark [Medium, 175 hrs]

The kotlinx-benchmark library is an open-source tool designed for benchmarking Kotlin code across multiple platforms, including the JVM, JS, WasmJs, and Native. Despite its broad compatibility, the library currently does not support benchmarking on Android. This project aims to bridge that gap. The plan is to utilize an existing Android library, such as androidx.benchmark, behind the scenes to integrate this functionality. A key aspect of the project will be ensuring that all features currently available for other platforms are also supported on Android, maintaining the library's multiplatform utility.

Expected outcomes

Integration of benchmarking support for Android platforms in kotlinx-benchmark, ensuring feature parity with other platforms.

Skills required (preferred)

Kotlin, Android Development, Benchmarking

Possible mentor

Abduqodiri Qurbonzoda, JetBrains
Rahul Ravikumar, Google

Enabling click-to-run for kotlinx-benchmark benchmarks in IntelliJ IDEA [Medium, 175 hrs]

kotlinx-benchmark is an open-source library for benchmarking multiplatform code written in Kotlin. It includes a Gradle plugin that, when applied, provides tasks for running benchmarks. However, executing these tasks requires navigating to the IDE's Gradle panel or using the terminal. Additionally, running a specific benchmark necessitates further steps, adding to the complication. To mitigate this inconvenience and streamline the process, this project aims to enable users to run an individual benchmark or an entire suite directly from the IntelliJ IDEA interface, mirroring the convenience offered for unit tests. Achieving this goal may necessitate collaboration with the IntelliJ IDEA team and/or contributions directly to the IntelliJ project.

Expected outcomes

Integration of click-to-run functionality for kotlinx-benchmark benchmarks in IntelliJ IDEA, improving user experience.

Skills required (preferred)

Kotlin, IntelliJ IDEA Plugin Development, Benchmarking

Possible mentor

Abduqodiri Qurbonzoda, JetBrains

Google Summer of Code with Kotlin 2023

This article contains the list of project ideas for Google Summer of Code with Kotlin 2023.

> Google Summer of Code 2023 has already ended. If you want to participate in GSoC 2024, check out this list of project ideas.

Project ideas

Kotlin Multiplatform protobufs [Hard, 350 hrs]

Description

Add support for Kotlin/Common protos to protoc with Kotlin/Native (iOS) runtime and Objective-C interop.

Motivation

While protobufs have many platform implementations, there isn't a way to use them in Kotlin Multiplatform projects.

Expected outcomes

Design and build Kotlin Multiplatform Protobuf support, culminating in contributions to:

- GitHub – protocolbuffers/protobuf: Protocol Buffers – Google's data interchange format
- GitHub – google/protobuf-gradle-plugin
- Kotlin Multiplatform Gradle Plugin

Skills required (preferred)

- Kotlin
- Objective-C
- C++

Kotlin Compiler error messages [Hard, 350 hrs]

Description

Add improved compiler error messages to the K2 Kotlin compiler: more actionable and detailed information (like Rust has).

Motivation

Rust compiler error messages are often regarded as being by far the most helpful of any compiler. The Kotlin K2 compiler provides a great foundation for better compiler errors in Kotlin but this potential is somewhat untapped.

Expected outcomes

Using StackOverflow and other data sources, uncover common compiler errors which would have significant value to users. Make contributions back to the compiler to improve those error messages.

Skills required (preferred)

- Kotlin
- Compiler architecture

Kotlin Multiplatform libraries [Easy or Medium, 175 or 350 hrs]

Description

Create and deliver (to Maven Central) Kotlin Multiplatform libraries that are commonly needed. For instance, compression, crypto.

Motivation

Kotlin Multiplatform is still fairly new and could use some additional libraries which are either platform independent (Kotlin/Common) and/or have platform implementations (`expect` / `actual`).

Expected outcomes

Design and deliver at least one Kotlin Multiplatform library with a greater priority on JVM/Android and Kotlin/Native (iOS) than other targets (Kotlin/JS).

Skills required (preferred)

- Kotlin
- Objective-C

Groovy to Kotlin Gradle DSL Converter [Medium, 350 hrs]

Description

The project aims to create a Groovy-to-Kotlin converter with a primary focus on Gradle scripts. We will start from basic use cases, such as when a user wants to paste Groovy-style dependency declarations to a Kotlin script and the IDE automatically converts them. Later, we will start supporting more complex code constructs and conversions of complete files.

Motivation

The Kotlin Gradle DSL is gaining popularity, so much so that it will soon become the default choice for building projects with Gradle. However, many documents and resources about Gradle still refer to Groovy, and pasting Groovy samples into `build.gradle.kts` requires manual editing. Furthermore, many new features around Gradle will be in Kotlin first, and consequently users will migrate from the Groovy DSL to the Kotlin DSL. The automatic code conversion of a build setup will therefore greatly ease this migration, saving a lot of time.

Expected outcomes

A plugin for IntelliJ IDEA that can convert Groovy code to Kotlin with the main focus on the Gradle DSL.

Skills required (preferred)

- Basic knowledge of Gradle
- Basic knowledge of parsers and how compilers work in general
- Basic knowledge of Kotlin

Eclipse Gradle KTS editing [Medium, 350 hrs]

Description

Improve the experience of editing Gradle Kotlin Scripts (KTS) in Eclipse.

Motivation

IntelliJ IDEA and Android Studio have great support for editing KTS Gradle build scripts, but the Eclipse support is lacking. Ctrl-Click to definition, Code completion, Code error highlighting could all be improved.

Expected outcomes

Make contributions to the Gradle Eclipse plugin that improve the developer experience for editing KTS.

Skills required (preferred)

- Kotlin
- Gradle
- Eclipse platform and plugins

Improve support for parameter forwarding in the Kotlin Plugin for IntelliJ IDEA [Medium, 350 hrs]

Description and motivation

The Kotlin plugin provides Kotlin language support in IntelliJ IDEA and Android Studio. In the scope of this project, you will improve parameter forwarding support for the plugin.

To prefer composition over inheritance is a widely known principle. IntelliJ IDEA provides great support for writing code that uses inheritance (completion and quick-fixes the IDE suggests), but the support for code that uses composition instead of inheritance has yet to be implemented.

The main problem of working with code that heavily uses composition is parameter forwarding. In particular:

- The IDE doesn't suggest completing parameter declarations that can be forwarded as arguments to other functions that currently use default parameter values.
- The IDE doesn't rename the chain of forwarded parameters.
- The IDE doesn't provide any quick-fixes that fill in all the required arguments with parameters that can be forwarded.

One notable example where such support would be greatly appreciated is Jetpack Compose. Android's modern tool kit for building UI, Jetpack Compose heavily uses function composition and parameter forwarding. It quickly becomes tedious to work with `@Composable` functions because they have a lot of parameters. For example, `androidx.compose.material.TextField` has 19 parameters.

Expected outcomes

- Improved parameter and argument completion suggestions in IntelliJ IDEA.
- Implemented IDE quick-fixes that suggest filling in all the required arguments with parameters with the same names and types.
- The **Rename** refactoring renames the chain of forwarded parameters.
- All other IDE improvements around parameter forwarding and functions that have a lot of parameters.

Skills required (preferred)

- Knowledge of Kotlin and Java
- Ability to navigate in a large codebase

Enhance the kotlinx-benchmark library API and user experience [Easy, 175 hrs]

Read the blog post about this project

Description

`kotlinx-benchmark` is an open-source library for benchmarking multiplatform code written in Kotlin. It has a barebones skeleton but lacks quality-of-life features, such as fine-grained benchmark configuration (like time units, modes), feature parity between JVM and Kotlin/Native benchmarking, a command-line API, and modern Gradle support. Its documentation, integration tests, and examples are also lagging.

Motivation

The library has already been implemented, but it is sometimes difficult to use correctly and confuses some users. Improving the library's user experience would greatly help the Kotlin community.

Expected outcomes

- The library has clear documentation with usage examples.

- The library API is simple and easy to use.
- Options for benchmarking Kotlin/JVM code are also available for benchmarking code on other platforms.

Skills required (preferred)

- Kotlin
- Gradle internals

Parallel stacks for Kotlin Coroutines in the debugger [Hard, 350 hrs]

Read the blog post about this project

Description

Implement Parallel Stacks view for Kotlin coroutines to improve the coroutine debugging experience.

Motivation

Currently, support for coroutines debugging is very limited in IntelliJ IDEA. The Kotlin debugger has the **Coroutines Panel** that allows a user to view all of the coroutines and their states, but it's not very helpful when debugging an application with lots of coroutines in it. The JetBrains Rider has the Parallel Stacks feature that allows a user to inspect threads and their stack traces in a graph view, which could be a great way of inspecting coroutines.

Expected outcomes

Using the Kotlin coroutines debugger API, develop the IntelliJ IDEA plugin which would add the parallel stacks view for coroutines to the debugger. Find ways to improve the graph representation of coroutines.

Skills required (preferred)

- Kotlin
- Kotlin coroutines
- IntelliJ IDEA plugin development

Contribution

Kotlin is an open-source project under the Apache 2.0 License. The source code, tooling, documentation, and even this website are maintained on GitHub. Kotlin is developed by JetBrains, but we are always on the lookout for more people to help us.

Participate in Early Access Preview

You can help us improve Kotlin by participating in Kotlin Early Access Preview (EAP) and providing us with your valuable feedback.

For every release, Kotlin ships a few preview builds where you can try out the latest features before they go to production. You can report any bugs you find to our issue tracker YouTrack and we will try to fix them before a final release. This way, you can get bug fixes earlier than the standard Kotlin release cycle.

Contribute to the compiler and standard library

If you want to contribute to the Kotlin compiler and standard library, go to JetBrains/Kotlin GitHub, check out the latest Kotlin version, and follow the instructions on how to contribute.

You can help us by completing open tasks. Please keep an open line of communication with us because we may have questions and comments on your changes. Otherwise, we won't be able to incorporate your contributions.

Contribute to the Kotlin IDE plugin

Kotlin IDE plugin is a part of the IntelliJ IDEA repository.

To contribute to the Kotlin IDE plugin, clone the IntelliJ IDEA repository and follow the instructions on how to contribute.

Contribute to other Kotlin libraries and tools

Besides the standard library that provides core capabilities, Kotlin has a number of additional (kotlinx) libraries that extend its functionality. Each kotlinx library is developed in a separate repository, has its own versioning and release cycle.

If you want to contribute to a kotlinx library (such as kotlinx.coroutines or kotlinx.serialization) and tools, go to Kotlin GitHub, choose the repository you are interested in and clone it.

Follow the contribution process described for each library and tool, such as kotlinx.serialization, ktor, and others.

If you have a library that could be useful to other Kotlin developers, let us know via feedback@kotlinlang.org.

Contribute to the documentation

If you've found an issue in the Kotlin documentation, feel free to check out the documentation source code on GitHub and send us a pull request. Follow these guidelines on style and formatting.

Please keep an open line of communication with us because we may have questions and comments on your changes. Otherwise, we won't be able to incorporate your contributions.

Translate documentation to other languages

You are welcome to translate the Kotlin documentation into your own language and publish the translation on your website. However, we won't be able to host your translation in the main repository and publish it on kotlinlang.org.

This site is the official documentation for the language, and we ensure that all the information here is correct and up to date. Unfortunately, we won't be able to review documentation in other languages.

Hold events and presentations

If you've given or just plan to give presentations or hold events on Kotlin, please fill out the form. We'll feature them on the event list.

KUG guidelines

A Kotlin User Group, or KUG, is a community that is dedicated to Kotlin and that offers you a place to share your Kotlin programming experience with like-minded people.

To become a KUG, your community should have some specific features shared by every KUG. It should:

- Provide Kotlin-related content with regular meetups as the main form of activity.
- Host regular events (at least once every 3 months) with open registration and without any restriction for attendance.
- Be driven and organized by the community, and it should not use events to earn money or gain any other business benefits from members and attendees.
- Follow and ensure a code of conduct to provide a welcoming environment for attendees of any background and experience (check out our recommended Code of Conduct).

There are no limits regarding the format for KUG meetups. They can take place in whatever fashion works best for the community, whether that includes presentations, hands-on labs, lectures, hackathons, or informal beer-driven get-togethers.

For Kotlin User Group brand assets, see Kotlin brand assets documentation.

How to run a KUG?

- To promote group cohesion and prevent miscommunication, we recommend keeping to a limit of one KUG per city. Check out the list of KUGs to see if there is already a KUG in your area.
- Use the official KUG logo and branding. Check out the branding guidelines.
- Keep your user group active. Run meetups regularly, at least once every 3 months.
- Announce your KUG meetups at least 2 weeks in advance. The announcement should contain a list of talks and the names of the speakers, as well as the location, timing, and any other crucial info about the event.
- KUG events should be free or, if you need to cover organizing expenses, limit prices to a maximum of 10 USD.
- Your group should have a code of conduct available for all members.

If your community has all the necessary features and follows these guidelines, you are ready to Apply to be a new KUG.

Have a question? Contact us

Support for KUGs from JetBrains

Active KUGs that host at least 1 meetup every 3 months can apply for the community support program, which includes:

- Official KUG branding.
- A special entry on the Kotlin website.
- Free licenses for JetBrains products to raffle off at meetups.
- Priority support for Kotlin events and campaigns.

- Help with recruiting Kotlin speakers for your events.

Support from JetBrains for other tech communities

If you organize any other tech communities, you can apply for support as well. By doing so, you may receive:

- Free licenses for JetBrains products to raffle off at meetups.
- Information about Kotlin official events and campaigns.
- Kotlin stickers.
- Help with recruiting Kotlin speakers for your events.

Disclaimer: Support and/or any assistance provided by JetBrains is subject to its discretion and compliance with regulatory requirements and applicable laws by the recipient.

Kotlin Night guidelines

Kotlin Night is a meetup that includes 3-4 talks on Kotlin or related technologies.

For Kotlin Night brand assets, see Kotlin brand assets documentation.

Event guidelines

- Please use the branding materials we've provided. Having all events and materials in the same style will help keep the Kotlin Night experience consistent.
- Kotlin Night should be a free event. A minimal fee can be charged to cover expenses, but it should remain a non-profit event.
- The event should be announced publicly and open for all people to attend without any kind of discrimination.
- If you publish the contents of the talks online after the event, they must be free and accessible to everyone, without any sign-up or registration procedures.
- Recordings are optional but recommended, and they should also be made available. If you decide to record the talks, we suggest having a plan to ensure the quality is good.
- The talks should primarily be about Kotlin and should not focus on marketing or sales.
- The event can serve food and drinks optionally.

Event requirements

JetBrains is excited to support your Kotlin Night event. Because we want all events to provide the same high-quality experience, we need organizers to ensure that some basic requirements are met for the event to receive JetBrains support. As an organizer, you are responsible for the following aspects of the event:

1. The location and everything required to host the event, including booking a comfortable venue. Please make sure that:

- All the participants are aware of the exact date, place, and starting time of the event, along with the event schedule and program.
- There is enough space as well as food and beverages, if you provide them, for everyone.
- You have a plan with your speakers. This includes a schedule, topics, abstracts for the talks, and any necessary equipment for the presentations.

2. Content and speakers
    - Feel free to invite presenters from your local community, from neighboring countries, or even from all over the globe. You don't have to have any JetBrains representatives or speakers at your event. However, we are always happy to hear about more Kotlin Nights, so feel free to notify us.
3. Announcements and promotion
    - Announce your event at least three weeks before the date of a meetup.
    - Include the schedule, topics, abstracts, and speaker bios in the announcement.
    - Spread the word on social media.
4. Providing event material to JetBrains after the event
    - We would be glad to announce your event at kotlinlang.org, and we would appreciate it if you provided slides and video materials for a follow-up posting.

JetBrains support

JetBrains provides support with:

- Access to Kotlin Night Branding, which includes the name and logos
- Merchandise, such as stickers and t-shirts for speakers and small souvenirs for attendees
- A listing for the event on the Kotlin Talks page
- Help to reach out to speakers to take part in the event, if necessary
- Help to find a location if possible (via contacts, etc.), as well as help to identify possible partnerships with local businesses

Code of conduct and guidelines for Kotlin Slack

Kotlin Slack aims to be an inclusive space committed to providing a friendly, safe and welcoming environment for all, regardless of gender, sexual orientation, ability, ethnicity, socioeconomic status, and religion (or lack thereof).

For this to be the case, it is vital that we all follow a basic set of guidelines and most importantly, adhere to the code of conduct. As such, please make sure you read this Code of Conduct and Basic Usage Guidelines in its entirety. This isn't your regular License Agreement that you should scroll through and agree blindly. It's here for a reason and also contains practical information.

- How to behave
- How not to behave
- How to report issues
- Moderators

- Basic usage guidelines
- Moderators
- Copyright

How to behave

- Participate in an authentic and active way. In doing so, you contribute to the health and longevity of this community.
- Exercise consideration, respect and empathy in your speech and actions. Remember, we have all been through different stages of learning when adopting technologies.
- Refrain from demeaning, discriminatory, or harassing behavior and speech.
- Disagreements on things are fine, argumentative behavior or trolling are not.

How not to behave

- Do *not* perform threats of violence or use violent language directed against another person.
- Do *not* make jokes of sexist, racist, homophobic, transphobic, ableist or otherwise discriminatory nature, or use language of this nature.
- Do *not* post or display sexually explicit or violent material.
- Do *not* post or threaten to post other people's personally identifying information ("doxing").
- Do *not* make personal insults, particularly those related to gender, sexual orientation, race, religion, or disability.
- Do *not* engage in sexual attention. This includes sexualized comments or jokes and sexual advances.
- Do *not* advocate for, or encourage, any of the above behavior.

How to report issues

If someone is acting inappropriately or violating this Code of Conduct in any shape or form, and they are not receptive to your feedback, or you prefer not to confront them, please get in touch with one of the Administrators. The main Administrators are Ilya Ryzhenkov (@orangy) and Hadi Hariri (@hhariri).

Basic usage guidelines

There are over 50 000 users on many different timezones using the Kotlin Slack, and the number is growing rapidly. The influx of messages per day and the numerous channels can lead to a lot of noise and little value in the long run. If we all follow a set of guidelines, it can help make things more useful and bearable for everyone.

- Please remember this is a Slack team for Kotlin. If you have generic questions that are about a technology (which may or may not be used with Kotlin), maybe it's better to use another forum, such as StackOverflow.
- This Slack is not an official support channel. It is a place where the community hangs out along with some members of the JetBrains and Kotlin team (suffix [JetBrains]).
- This Slack is not the best place for reporting bugs. For this, please use YouTrack.
- Find the right channel to ask your question. There are channels for pretty much every topic.

- New channels should be focused around a well-known technology or area of interest. Create them sparingly. And before requesting for a new channel, make sure it doesn't exist in any other shape or form. Ask an administrator to create a new channel on the #meta channel. If you do end up creating a channel, make sure you set the topic.
- Please refrain from cross-posting the same message on multiple channels. It is considered spamming.
- When you ask a question, please be patient. Don't repeat it. Or at least not immediately.
- Please do not ping or mention someone directly to get your questions answered, especially project owners, whether the project is Kotlin or other, unless they specifically indicate that you can.
- Don't split messages into multiple ones. Ask it all in a single message.
- Use code blocks. Don't paste code as plain text. Slack supports Kotlin markup. If the code you are pasting is longer than a few lines, use "Code or text snippet" available from `+` menu next to message input. Only first few lines will be displayed to all users, and people interested in the code can expand your code to look into details.
- While it's polite to say "Hi" or "I have a question" before asking something, it doesn't scale and leads to noise. You can say hello in the same message you ask the question if you like.
- Using threads is not required, but do take into account that it does allow people to more easily follow conversations, especially those jumping in late.
- Use reactions to show gratitude as opposed to a message. It reduces the noise and gets the message across.
- Don't use reactions to tell people they're in the wrong place or asking the wrong question. If they're on the wrong channel, point them to the right one. If their question is badly worded, help them correct it. Have empathy.
- Take into account cultural differences. As they say, what the British say isn't what the British mean. Remember this both as the receiver and producer of messages.
- Don't create integrations with Slack. Given this is running on the free tier, the number is limited, and thus it won't be approved.
- @channel, @here and other forms of notifications are disabled, even if you own a channel (unfortunately, Slack doesn't allow fine-grained permissions).
- Use the #meta channel if you're unsure about how to do something.

Moderators

A moderator is a member of the Kotlin Slack community who volunteers to keep the kotlinlang Slack a safe and welcoming place for other members. Moderators are approved by kotlinlang Slack administrators. Their responsibilities and the guidelines they follow are described below.

Responsibilities

- Monitor Slack channels to ensure compliance with the Code of Conduct.
- Help community members follow the rules.
- If a channel has additional rules, ensure these are visible and up to date.
- Monitor the #reports and #meta channels.
- Participate in the private #moderators channel.

Guidelines

- Moderators communicate in a friendly manner and do their best to help other community members.
- Any changes suggested by a moderator should be discussed by all moderators and administrators before coming into effect.

Process

- Each moderator oversees at least one channel, or more if possible.
- When moderators notice inappropriate behavior, they explain the rules and guidelines to the members and help figure out how to correct the unwanted behavior. If the unwanted behavior persists, moderators report the case to administrators for further actions. In the case of obvious and/or particularly blatant violations, offending members can be reported immediately.
- To set up or update a channel's rules, the moderator initiates a change proposal and discusses it with the appropriate community members.
- Communication regarding moderation takes place in the private #moderators channel.
- If community members notice that a moderator is ignoring their responsibilities (or engaging in any unwanted behavior), they can alert administrators.

Moderator status acquisition and revocation process

- Any member is welcome to apply to be a moderator once they have been in the Slack community for longer than 6 months.
- Moderator status is provided based upon the decision of the administrators.
- Moderator status can be revoked if (this list is not exhaustive and can be updated on a case-by-case basis):
  - A moderator ignores their responsibilities, which leads to issues in a channel.
  - A moderator violates these guidelines.

The list of moderators

At the moment we have 17 confirmed moderators, and they will be responsible for observing a total of 64 channels. For all other channels, if any issues arise, members can ping any of the moderators or admins directly, or they can post a message in #meta.

- Alexander Nozik (@altavir) – #mathematics, #science, #datascience, #education
- Anderson Lameck (@andylamax) – #coroutines, #kotlin-native, #webassembly, #serialization, #random, #javascript, #react

Kotlin brand assets

Kotlin logo

Our logo consists of a mark and a typeface. The full-color version is the main one and should be used in the vast majority of cases.

Download all versions

Our logo and mark have a protective field. Please position the logo so that other design elements do not come into the box. The minimum size of the protective field is half the height of the mark.

Kotlin logo proportions

Pay special attention to the following restrictions concerning the use of the logo:

- Do not separate the mark from the text. Do not swap elements.
- Do not change the transparency of the logo.
- Do not outline the logo.
- Do not repaint the logo in third-party colors.
- Do not change the text.
- Do not set the logo against a complex background. Do not place the logo in front of a bright background.

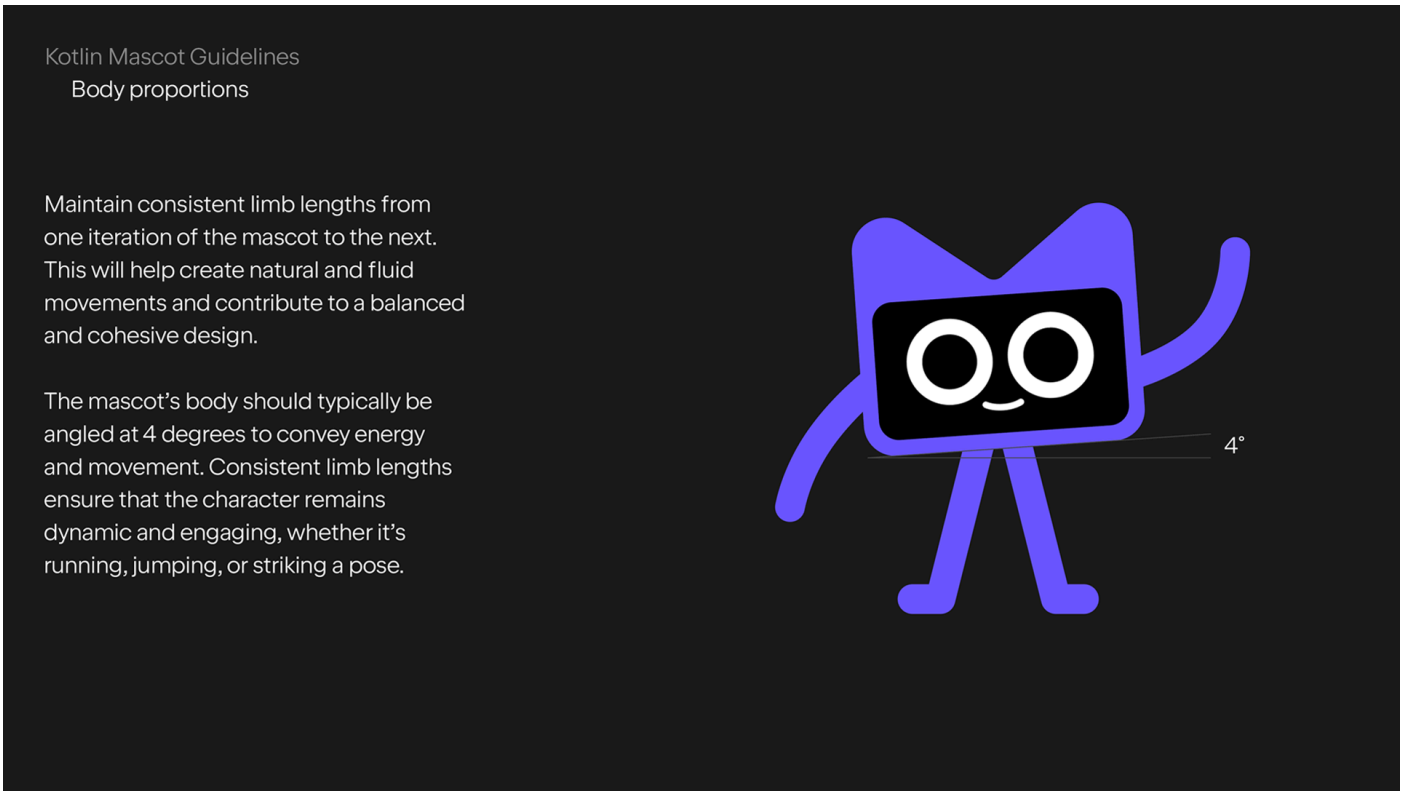
Read the Kotlin brand usage guidelines.

Kotlin ecosystem logos

The Kotlin brand package also includes logos for several official Kotlin ecosystem projects, libraries, frameworks, and technologies. These assets follow the same visual principles as the Kotlin logo and help ensure consistent representation across the ecosystem.

The package contains logos for:

- Kotlin Foundation
- Kotlin Multiplatform (KMP)
- Talking Kotlin
- Compose Multiplatform (CMP)
- Compose Hot Reload
- Ktor

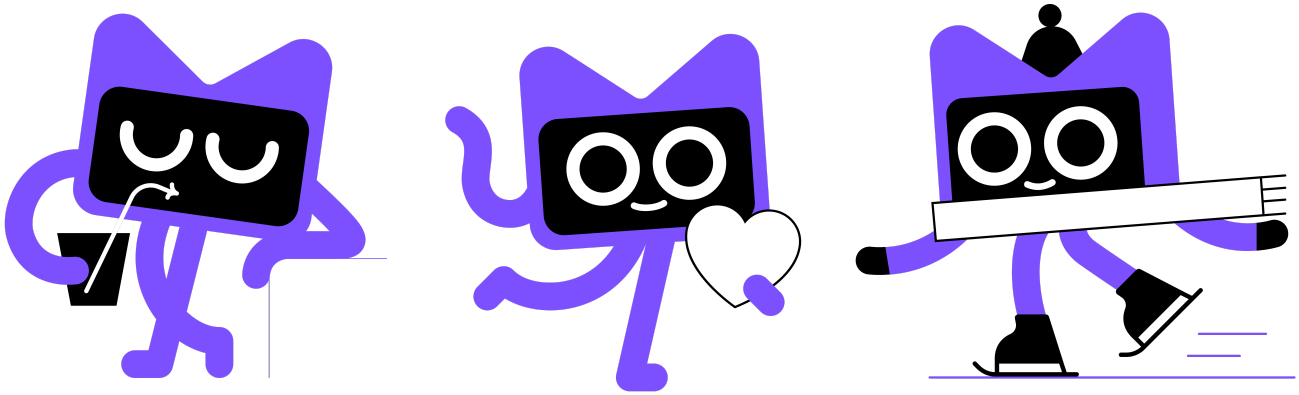


- Exposed

You can find these logos in the same download bundle:

Download all versions

Kotlin mascot



Meet Kodee, the Kotlin mascot and your friendly companion who's always there to encourage and inspire your creativity. When using it, we ask you to follow these simple guidelines.

Kotlin mascot Kodee proportions

You can use Kodee in your digital and print materials. For this purpose, we have prepared a variety of Kotlin mascot assets for you to download and explore.

Kotlin mascot Kodee in action

Kotlin User Group brand assets

We provide Kotlin user groups with a logo that is specifically designed to be recognizable and convey a reference to Kotlin.

- The official Kotlin logo is associated with the language itself. It should not be used otherwise in different scopes, as this could cause confusion. The same applies to its close derivatives.
- User groups logo also means that the opinions and actions of the community are independent of the Kotlin team.
- Your opinions don't have to agree with ours, and we think this is the most beneficial model for a creative and strong community.

Style for user groups

Since the launch of the Kotlin community support program at the beginning of 2017, the number of user groups has multiplied, with around 2–4 new user groups joining us every month. Please check out the complete list of groups in the **Kotlin User Groups** section to find one in your area.

We provide new Kotlin user groups with a user group logo and a profile picture.

Branding image

There are two main reasons why we are doing it:

- Firstly, we received many requests from the community asking for special Kotlin style branded materials to help them be recognized as officially dedicated user groups.
- Secondly, we wanted to provide a distinct style for the user group and community content to make it clear which Kotlin-related materials are from the official team and which are created by the community.

Create the logo of your user group

To create a logo of your users group:

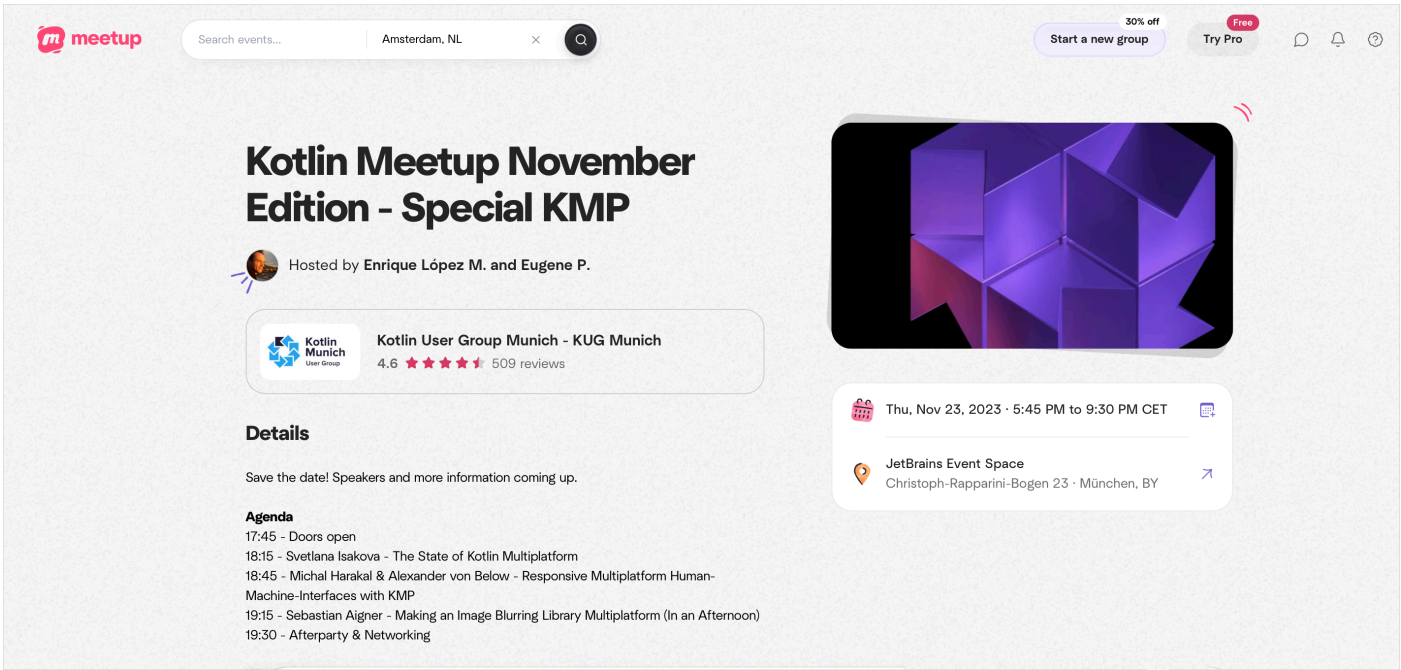
1. Copy the Kotlin user group logo file to your Google Drive (you have to be signed in to your Google account).
2. Replace the **Your City** text with the name of your user group.
3. Download the picture and use it for the user group materials.

Belarusian Kotlin User Group sample

Belarusian Kotlin User Group Profile Picture sample

You can download a set of graphics including vector graphics and samples of cover pictures for social networks.

Create your group's profile picture for different platforms



To create your group's profile picture:

1. Make a copy of the Kotlin user group profile picture file to your Google Drive (you have to be signed in to your Google account).
2. Add a shortened name of the user group's location (up to 4 capital symbols according to our default sample).
3. Download the picture and use it for your profiles on Facebook, Twitter, or any other platform.

Create meetup.com cover photo

To create a cover photo with a group's logo for meetup.com:

1. Make a copy of the picture file to your Google Drive (you have to be signed in to your Google account).
2. Add a shortened name of the user group's location to the logo on the right upper corner of the picture. If you want to replace the general pattern with a custom picture, click on the background pattern-picture, choose 'Replace Image', then 'Upload from Computer' or any other source.
3. Download the picture and use it for your profile on meetup.com.

Kotlin Night brand assets

JetBrains provides branding and materials for Kotlin Night events. Our team will prepare digital assets for the event promotion and ship your merchandise pack containing stickers and t-shirts. Check out what we have to make your Kotlin Night fun!

Download all assets

Social media

Stickers can be used to brand any media necessary for a Kotlin Night. Just stick them on anything you can get your hands on. It's fun!

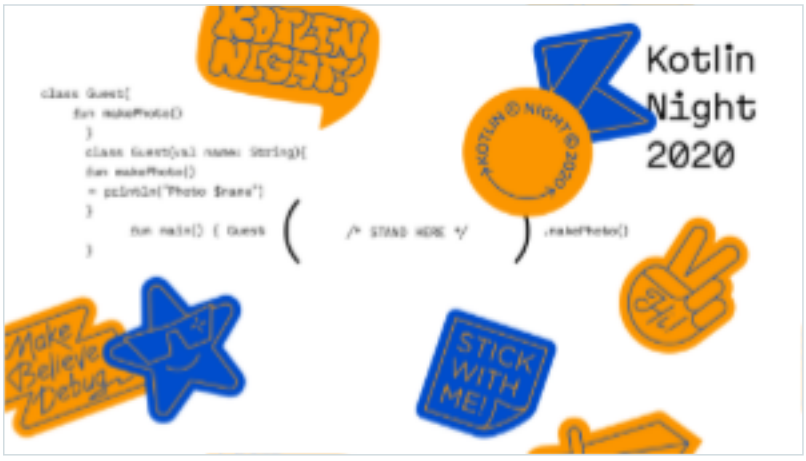
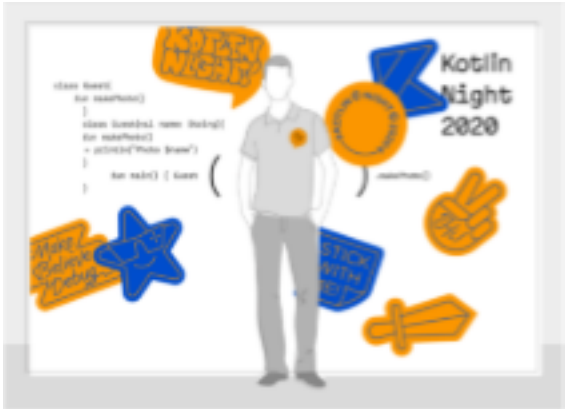
Cover Social

Branding stickers

Stickers can be used to brand assets for a Kotlin Night. Just stick them on anything you can get your hands on. It is funny!



Example of usage



Stickers

Press-wall

You can decorate a press wall with stickers for unforgettable event pictures.

Press-wall

Example of usage

Press Wall

Sticky badges

Use stickers as badges for the attendees and boost networking at the event!

Board for stickers

Or you can provide a board where your guests can paste stickers with their impressions, feedback, and wishes.

board pack

T-shirts

Guests of the event are offered to paste stickers on the board with their impressions of the meeting. What does it mean to you?

Security

We do our best to make sure our products are free of security vulnerabilities. To reduce the risk of introducing a vulnerability, you can follow these best practices:

- Always use the latest Kotlin release. For security purposes, we sign our releases published on Maven Central with these PGP keys:
  - Key ID: **kt-a@jetbrains.com**
  - Fingerprint: **2FBA 29D0 8D2E 25EE 84C1 32C3 0729 A0AF F899 9A87**
  - Key size: **RSA 3072**
- Use the latest versions of your application's dependencies. If you need to use a specific version of a dependency, periodically check if any new security vulnerabilities have been discovered. You can follow the guidelines from GitHub or browse known vulnerabilities in the CVE base.

Starting with Kotlin 2.4.0, the Kotlin standard library for the JVM has an 18-month support window for each release line. Language releases (2. *x*. *0*) and the following tooling releases (2. *x*. *20*) belong to the same release line (2. *x*). To learn more about how we handle security vulnerabilities in the standard library for the JVM, see Standard library security support.

We always want to hear about any security issues you find. To report vulnerabilities that you discover in Kotlin, post a message directly to our issue tracker or send us an email.

For more information on how our responsible disclosure process works, see the JetBrains Coordinated Disclosure Policy.
